TO OUR READERS.

———— × ————

Every one must have had that temper-trying personage, a plain-spoken friend—one who is aptly described as "always calling a spade a spade," and as aptly might it be added, "and always using it as a spade" by digging with it unmercifully. We have such a friend, and you, our Readers, know her too; but so many months had elapsed without her delving into us that we began to hope—we think we did not hope that she was dead—but we began to hope that she had given us up as incorrigible. The cherished delusion is dissipated, for we have the note following—

"Cackleton Hall,
"*Innocents' Day*, 1869.

"Miss Penelope Pomeroy's compliments, and wishes to know what improvements the Editors intend to make in their Journal. They were very prone to changes at one time, and had a change of office, change of publishing day, and change of name; but now when other journals are making changes the Editors remain stagnant. Why don't they print the Journal on toned paper, or alter its type, or add some such department as 'Pug Dog and Parrot Chronicle' to its many titles? Miss P. P. knows both the Editors from their photographs, and begins to call them her 'old Gooseberries;' and by way of distinction she calls one her 'smooth old Gooseberry,' and the other her 'hairy old Gooseberry.'"

We shall not gratify Miss P. P. by revealing whether one of her 'old Gooseberries' became more red and the other more pale upon perusing that note. They have not even posted to her a reply, but they here print it.

"The Editors' compliments to Miss Penelope Pomeroy, and they do not purpose making any change in the Journal, and for that most satisfactory of reasons—there is no occasion for it. Their Readers are satisfied, their Correspondents are satisfied, and the Editors are satisfied; and they are quite contented to be called 'her Gooseberries,' because they hope it intimates her intention to preserve them."

Our Readers will appreciate the concluding sentence; and we have purposely omitted any allusion to the senility of the Gooseberries, because we feel there is no occasion for it.

INDEX.

Aberdeen Poultry Show, 681
Abies, Douglasii, 227; Pattoniana, 287
Abutilon megapotamicum or vexillarium, 341
Acer rufinerve, var. albo-limbatum, 247
Acorn in water, 485
Aerides japonicum, 303

From observations taken near London during the last forty-two years, the average day temperature of the week is 74 7°; and its night temperature 50 7° The greatest heat was 97°, on the 5th, 1852; and the lowest cold 35°, on the 7th, 1864. The greatest fall of rain was 1.18 inch.

THE ROSE.

IN no flower are usefulness and beauty more happily combined than in the Rose; so highly are its blossoms esteemed, that although those of some members of its family expand early in spring, and other sections flower throughout the summer, and continue to do so till winter nips them, yet we are not satisfied, for no sooner do we perceive the approach of winter than our thoughts revert to our pot Roses, which, having matured their growth, and been gradually prepared for the purpose, are now brought forward in successive relays, in order to afford a continuous supply of their charming flowers throughout the winter. And thus do we wreath the year round with a bright garland of the blossoms of our floral queen, most gladly yielding ourselves to the refining influence of her gentle sway; never swerving from our allegiance, never faltering in our loyalty, although at times rudely assaulted by the rampant followers of the republican Mrs. Pollock, who, shaking their tricolor flags in our faces, seek to dazzle us with their brilliancy. Tricolors forsooth! let them try colours with the Rose, and their harsh leaves will quickly have to succumb to the delicacy and polish of a Rose petal.

Amongst the different sections of the Rose family, none are more justly esteemed than the Tea and Noisette Roses, which are invaluable on account of their coming into bloom early in spring, and also succeeding the latest autumnal blooms of the Perpetuals; and when planted in sufficient numbers, they will always ensure a supply of flowers until severe frost set in. The weaker kinds, such as Gloire de France, Elise Sauvage, and Devoniensis are admirably adapted for filling up any vacant spaces between fruit trees on walls; and the more rampant kinds are quite worthy of the greater space which their vigorous growth demands. Nothing suits Cloth of Gold so well as a large gable or two over which it may ramble unchecked by the pruning knife. Solfaterre, too, and Gloire de Dijon are lovely ramblers, which if pruned much make a strong growth, but do not bloom so freely as they would if their growth were only slightly shortened. Lamarque is not so rampant as some, but for purity and delicacy of colour it is unrivalled. In cutting some flowers for bouquets a few days ago, I accidentally happened to put a partly-expanded blossom of Lamarque with two flowers of the old Crimson China; each Rose had its buds and foliage, and I thought nothing could be more lovely. The best kinds of Roses of this section that I have cultivated are those already named, together with Louise de Savoie, Céline Forestier, Maréchal Niel, Safrano for its beautiful buds, Souvenir d'un Ami, and Miss Isabella Grey, a fickle maid in whom no dependance can be placed. Last summer the blossoms of this expanded freely, and were most beautiful, but this season, although producing a profusion of buds, not one good flower has expanded; the whole of those on one strong plant, about two hundred in number, are "green-eyed monsters."

Nothing can be more beautiful than a wall covered with a well-arranged collection of Roses in full bloom; and although wall-space is generally devoted to the choicest and more delicate Tea and Noisette varieties, yet the beauty of Roses of these classes is much enhanced if an occasional deep crimson, such as Charles Lefebvre, Senateur Vaisse, or the more brilliant Souvenir de Charles Montault, or perhaps such sterling pink varieties as a Jules Margottin and a John Hopper be introduced. My own rule in planting is to have every third plant either a crimson or pink.

In concluding these few notes on my favourite flower, permit me again to urge upon all lovers of the Rose the adoption of pyramids in place of standards. I feel quite certain that no person after seeing the effect produced by a symmetrical pyramid will ever plant another standard. Of a few plants of various sizes growing here, and just coming into bloom, I have selected one as a model plant, whose size and shape I shall endeavour to imitate as closely as possible in a number of young plants which I have in training. The plant I allude to is a Jules Margottin; the diameter of its base is 2 feet 8 inches, and it is 3 feet 6 inches high; it has a crop of at least fifty trusses, the principal buds of which are just beginning to expand; its foliage is abundant and thriving, and altogether it is a picture of health and beauty; so when I state that this plant is the offspring of a cutting made by my own hands in August, 1866, I think it will be granted the result obtained is very satisfactory. One or two plants of the same age are larger than this, but they are not so symmetrical; for unless the height of a plant increases in proportion to its diameter, it quickly assumes the appearance of the old-fashioned bush; but a true pyramid presents a happy medium between the squat ungainliness of the bush and the stiff formality of the pillar.—Edward Luckhurst, *Egerton House Gardens, Kent.*

THE REV. W. F. RADCLYFFE'S, OKEFORD FITZPAINE.

It is not given to Sir Joseph Hawley always to win the Derby, to Oxford always to carry off the laurels at Lord's, to the best marksman to pocket the Queen's prize at Wimbledon: so neither is it given to every horticulturist, however distinguished, to record successes. Here is Mr. Pearson telling us at last, what I recollect being severely taken to task for, that orchard houses *pur et simple* (*i.e.*, without heat), are of very little use when seasons are unpropitious. Here are our beautiful Peach trees all brown and burnt, Cherries by the bushel lying underneath our trees, and failure of fruit crop the too-general cry. So instead of having to sing, as I have previously done, in loud tones of our friend's garden, of his Roses and his Peach trees, I must this year as a faithful chronicler state that he has suffered tremendously, and that only his indomitable perseverance and skill could have surmounted the disastrous influences to which he is exposed. He neither possesses the beautiful Rose soil of Hertfordshire or Essex, nor rejoices in the shelter that enables many to

defy the asssults of Boreas. Although his soil is a vast improvement on that of Rushton, yet there is a certain steeliness about it which, in such a season as this has been, tends to make it what farmers call surly; his knowledge of its character and its wants is gradually altering this, but it must take some time before the neglect of former tenants can be repaired. Then, although situated on the slope of the hill, it is just on the brow, so that the winds have full play on it, and I am not sure whether the wall which he has built may not have aggravated the evil, for it affords a point of resistance to the south-west gales, such as a hedge does not, and sends the wind eddying round through the garden. Some idea of the force of the wind may be gathered from the fact that his first wall, a 9-inch one, was blown completely down, and that in protecting his fruit trees he is obliged to use stout canvas, and to fasten it on to the iron rods with copper wire, tarred twine being of no use whatever. The result of all this has been that his Roses have suffered a good deal; the wind has bruised the foliage, and so checked the circulation that a good deal of orange fungus (a thing almost unknown in good Rose soils, I believe), has made its appearance; with this he has no mercy, he cuts out the affected part as soon as it appears, and encourages thereby the growth of new shoots. That the wind is the cause of this is proved from the simple fact that in one corner of his garden which is sheltered the plants are in vigorous and robust health, without a sign of this fungus upon them.

I have before mentioned that Mr. Radclyffe is very shy of new sorts, and he is inclined to wait a couple of years before he introduces them into his garden; while no amount of his old favourites seems to satisfy him. Charles Lefebvre, for instance, meets you in all parts of the garden; grand blooms, 5 inches across. Duc de Cazes is another great favourite for the brilliancy of its tints. John Hopper and Jules Margottin also occupy a conspicuous place; while there are some sorts which we generally think highly of which he does not; for example, he has discarded me from his garden, and is inclined to send my daughter after me; but he has lost his heart to Marie Baumann. He had some blooms of it out, and each time that he went round the garden he returned to these again to take another fond gaze at them. It is without doubt a very beautiful Rose. I should just add, before leaving the Roses, that they were all making vigorous new growth, and would in a short time be full of fresh bloom.

The wall fruit trees were in wonderfully fine condition as far as appearances went, not a blistered leaf was to be seen, not an aphis, I believe, from beginning to end, and their general aspect was an evidence of how carefully they had been tended. Fruit was, as everywhere this year, very scarce; but when we are told that even glazed walls and orchard houses are no protection this season, it is not to be wondered at that the Peaches and Nectarines are few and far between. Since my last visit some standard Cherry trees have been added, and from trees from Sawbridgeworth planted on the 1st of April we had some delicious Early Lyons for dinner.

The Strawberries were looking very fine, but, as everywhere, late. I could hardly believe that the plants which I saw were those which I had seen as runners last year, but it was so; Cockscomb, Dr. Hogg, and Lucas were especially fine. Raspberries also had a heavy crop; while Potatoes were looking remarkably well. We had for dinner Royal Ashleaf, which has been in use since June 5th, and very excellent they were, far better than those I used to grow at Deal; so it must have a trial at Westwell.

I found our good friend hearty and genial as ever, and Stevie as original. My rosarian friends must congratulate me on my ecclesiastical preferment to the dignity of "Dean;" my modesty forbids my assuming the title, however; for alas! it only extends to the gardens at Okeford, where Stevie, hearing me called "D.," had converted it into Dean.—*D., Deal.*

HAND BOUQUETS.—No. 1.

Amateurs are seldom successful in making a good bouquet for the hand, as there is an amount of skill and patience required which few people are willing, if able, to bestow upon it.

The shape, according to the existing law of custom, should be circular, the centre slightly raised, with a gentle slope evenly kept to the edges. Underneath, the stems must be managed so as to be easily held in a lady's hand, and the weight must be light. But to obtain this combination, it is necessary to put the flowers together in an artificial manner.

Before the work is begun, care should be taken to have ready a plentiful supply of wet wool, or dried moss well soaked in water, and two sorts of wire, one as fine as horsehair, and the other rather thick and strong; a bundle of pliable sticks should also be provided. They may about 6 inches long, and the thickness of an ordinary Pelargonium stem. Young twigs from a Thorn bush, dried, and left in water for twenty-four hours before they are used, will answer the purpose very well. The stems of all the flowers are to be cut off, leaving only 1¼ inch to each head. This portion is bound round with a thin strip of wet wool, or a little wet moss, to keep it moist, and to prevent the wire bruising it, and an artificial stalk is then added, placing it close under the calyx of the flower. If the natural stem is soft, or full of sap, one of the prepared sticks will be the best; but if it is woody and tough, strong wire must be used. To bind on the sticks, fine wire is twined round and round from the bottom of the stick to the head of the flower, and crossed back again, which will render the whole stalk flexible. Wire stalks are twined round in the same manner, from the place where the natural stem is joined on.

The easiest way of making up a bouquet is to begin in the centre, and work round it in circles. This does not necessitate a formal arrangement of the flowers, but will materially help in keeping the shape perfect. To each circle and to each flower must be added sufficient wool or moss (the moss is preferable), to prevent the flowers crushing one another, and to enable them to be spread out at the top, while the stalks underneath are compressed into a small compass. Black thread is the best material with which to bind all the flowers together.

If full-blown flowers are used, they will generally require wiring before they are mounted, to keep them from shedding their petals. Roses, Camellias, Oleanders, &c., are treated in this way. A piece of fine wire is inserted through the calyx of the flower on one side, and brought out through the calyx on the other, another thread of wire being crossed over in the same manner; the four ends are then twisted together round the stem. For Pelargoniums and open flowers, a drop of clear gum dropped in the centre the day before they are wanted, will secure their petals, and will not spoil the look of the flowers. A bouquet well managed ought to look fresh for a week at least. Flowers will last longer if placed in water an hour or two before they are used.—L., *Laughton.*

CAULIFLOWER CULTURE.

The earliest crop of the season is produced from seed sown the previous autumn. The good old rule, "sow and plant often," in order to keep up a regular supply in good condition, does not apply to any vegetable with greater propriety than to that now under consideration. It is well to start with a recognition of this rule by sowing twice instead of once in autumn. The first sowing should be made about the middle of August, and the second fourteen days later. In those localities where the checking frosts of autumn set in early, these times may, perhaps, be found late enough, while in other districts I have found the last week of August quite early enough. It will depend entirely on the character of the season which of these two sowings may prove the most desirable from which to choose the main stock of plants for wintering in the best condition as to size and hardiness. Some seasons the earlier sowing may be found too large for wintering in frames, and in such cases the propriety of a second sowing becomes apparent.

Choice should be made of an open airy situation on which to sow the seed. The soil should, if possible, be moderately light, rich, and well pulverised. The seed should be sown thinly, so that the crop of young plants may not become crowded and weakly. If thick, and the season prove wet, mildew is very apt to destroy them. Should the weather and ground be dry, the seed should be steeped in water for twelve hours, and the ground well watered the night before it is sown. This secures a quick and healthy germination without resorting to the undesirable practice of watering the soil after the seed is sown. Many objections might be urged against watering seed beds in hot dry weather, with the view of promoting germination and healthy growth. The action and reaction caused by such a practice in some cases destroys the seed altogether, and the surface of the soil gets consolidated and caked over. By soaking the seeds and bed before sowing, and then shading it from the hot sun, a healthy germination is promoted with very little trouble.

As has already been remarked, the earliest Cauliflowers of the next season are produced from these autumn sowings; and as soon as they are ready to transplant, a border with a

due south and sheltered exposure should be got ready for them. As earliness is the chief object, the soil should not be heavy nor damp. A good dressing of thoroughly-rotted manure should be trenched or dug deeply into it, and every spadeful of the soil should be well pulverised. Hand-glasses should then be placed on the soil thus prepared, at about 2 feet apart one way, and 2½ feet the other. The most stocky and healthy plants that can be selected are planted five in each glass; one in each corner, and one in the centre. Although four or five plants are the number to be brought to maturity in these glasses, no harm results from putting a few more into each with the view of transplanting them in spriog. This, where framing is scarce, is often practised. Care, however, must be taken that they do not get crowded, or injury to the whole will be the result, and the transplanting of the superfluous stock should be done before rapid growth commences. When planted and watered, the light should be put over them, but not closely, and a slight shading afforded for a few hours in the middle of the day if the weather be hot.

After they take with the ground, it must be kept in mind that the more exposed they are in autumn, while they continue to make growth, the better will be their condition to stand the winter, should it be severe, and come away bold and strong in spring; consequently, the tops of the lights should be kept off, except to throw off heavy rains. When the winters are severe, they should be kept closely shut-up while the frost continues, and should be screened from sudden bursts of sunshine. If severe frosts take place after the sun gains sufficient power to thaw them quickly, they are more likely to suffer from sudden alternations of temperature than from continued severe frost. Generally this is all the shelter found necessary for moderate-sized plants that have not been crowded, and rendered tender thereby. In mild weather slugs are the principal devourers that must be looked after and destroyed in the usual way. If the surface of the soil is covered with the siftings of burned earth or charcoal, it is good for the plants, and prevents slugs from harbouring so much. If more have been wintered in the hand-glasses than can be left to come to maturity, they should be removed by the middle of March. If the hand-glasses are of the largest sizes, one plant in each corner and one in the middle may be left, as nice compact early heads are required rather than large ones; but if the glasses are smaller, one in each corner is enough. The surface of the soil should then be well stirred, all dead leaves removed, and a slight earthing-up of a few inches of light rich soil applied. On fine days a free exposure to air must be followed out, shutting them up at night to prevent the soil from losing the heat absorbed by day. They soon make rapid progress, and April adds greatly to their size and strength, and they are generally far a-head of spring-transplanted crops. The glasses should be removed entirely as soon as the plants outgrow them. A top-dressing of well-rotted manure should then be laid over the surface of the ground among and around the plants, and over all a covering of soil. This moulds up the plants and keeps them steady. In performing this operation the corner plants should be pressed away from the centre, to further prevent them from becoming crowded. This moulding-up must be efficiently and firmly done, so that the plants do not get blown about and loosened at the neck by high winds, and a basin should be left all round them to hold manure water. When from dry weather it becomes necessary to help them on with water, let it be a thorough soaking once a-week in preference to smaller quantities more frequently. A mulching should be applied after the first watering, and nothing is better for this than old hotbed manure.

In very cold damp situations it is advisable to pot up in October as many plants as are required for the desired number of glasses, in case, in the event of severe weather, they get crippled. In pots they can be wintered in a cold pit or frame, and turned out into the glasses as established plants, either to make up blanks or replace the whole stock. These will come away much earlier than transplanted plants, and in cold localities it is always advisable to have a few plants in pots to make up blanks under the glasses, if not for anything more important; for if the blanks are made up by transplanting, the plants so introduced do not keep pace with the established plants, and eventually get smothered.

Returning to the stock of young plants in the seed beds, the next consideration is to take steps to winter a stock of plants for planting out in good condition in spring, to succeed those under hand-glasses. The means to this end are to a great extent regulated by the climate of different parts of the country. Some localities are so favoured with climate that the Cauliflowers can be planted out in quarters like Cabbages, and generally stand the winter so managed. In others less mild it is necessary to prick them off under the shelter of a wall. In the majority of cases it is wise not to trust them without some more substantial means of protection, and it becomes necessary to put a quantity into temporary pits, with some means of covering them up in severe frosts, and still better are they under glass in cold frames and pits. For this purpose the latest sowing recommended generally supplies the most suitable plants, the earliest being generally too large, and not in such a good condition to stand the winter, and more likely to button in spring than less plants. The middle of October is a good time to transplant them into frames, which should stand dry and well exposed. Any moderately rich soil, such as common light garden soil, answers very well. The most healthy, stubby, and short-necked plants must be chosen, and planted in rows 4 inches apart each way. They may stand wider if space be plentiful; certainly not closer if fine plants are to be produced.

All the autumn and winter they must be freely exposed to light and air in mild weather, by pulling off the lights every morning and tilting them well up at night. Rain must be kept from them on all occasions, as a superabundance of moisture makes them grow too much, and more liable to suffer from frost. All decaying leaves must be removed when they appear, the surface of the soil kept stirred, and if some charred soil is strewn amongst them, it keeps the surface of the soil from becoming slimy and caked. In dull damp weather, when it becomes necessary to cover them up from severe frosts, it must be borne in mind that they are more likely to be killed by a sudden thaw than by a smart bite of frost. Therefore they should be kept covered up from light after the surface of the soil and the plants have become frozen, and not uncovered till they are completely thawed again; and then the covering should be removed, and light and air admitted by degrees. Mice and slugs are the enemies that are to be guarded against, for if allowed their own way they soon spoil a lot of plants—the former by eating the hearts out of them, and the latter by eating the stems below the leaves.

Looking at these Cauliflower plants that have been wintered in frames in cold localities, the next consideration is how to manage them so that they shall succeed those in hand-glasses in a south border. If transplanted into the open borders or quarters in March they receive a considerable check, even when lifted with balls and carefully planted, and are likely to get checked severely by frosts and cutting winds before they take hold of the ground, so that the earliest of them has little chance of being ready by the time the latest under the glasses are cut. To gain the object in view I know of no better plan than that of potting them up out of the frames the first week in February, and establishing them in pots in kindly quarters under glass, for a time at least. In this way they receive a comparatively slight check, and fine strong plants can be turned out with good balls by the end of March. They are also better able to contend with sun and wind, and are much earlier than those transplanted from the frames without being potted.

Four-inch pots are large enough for the strongest plants, while the smallest may have a size less. The soil should be rich, such as old Melon-bed loam and well-rotted leaf mould in equal proportions, with a slight sprinkling of fine bone dust and sand. A single crock in each pot is enough. They should be potted firmly, and room left in the pot to hold plenty of water when they require it. In lifting the plants from the frame, the object should be more to get the roots as entire as possible than to preserve a ball of earth to them. None of them should be discarded on account of their being small, if healthy; for the greater the variety in size, the longer and more regular the succession a given number of plants will afford. After being potted and well watered, they should be returned to the pit or frame and kept close for a time till they begin to take with the pots. Then they must be inured to full exposure, but always protected from frost, although in all other respects grown in a hard manner. The end of March, or, should the weather be cold, the beginning of April, is soon enough to plant them out, unless in more favoured localities. The ground intended for them should be trenched and well manured with thoroughly rotted dung. Some of the most forward plants should be planted in a border with a south exposure, on a rather light rich soil. Here they will succeed those in the glasses. The rest may be planted in the open quarters, where the earliest of them will follow up those in the early border. In performing

the operation of planting, circumstances must determine the exact way in which it is best performed. On heavy cold soils, upon which it is advisable to tread as little as possible after it is trenched, I have frequently left the trenching till the time of planting, and put the plants out as the trenching proceeded. Having a heap of light rich soil in readiness beforehand, a couple of spadefuls of it were put round the ball of each plant to give it a start. This may perhaps be considered a preferable way of doing the work on such soils, to that of first trenching the ground and then throwing out pits for the light soil, inasmuch as all treading of the ground is avoided. In free fine soils there is nothing necessary beyond setting the line and planting the plant-balls entire in the natural ground. They should always be planted at such a depth that the soil reaches up to the first leaves of the plants. Two feet by two will be plenty of room for producing moderate-sized heads. If large ones for the hall be an object, some of them may be planted wider; but for all practical purposes, 2 feet by 2 will be enough.

In heavy soils, slugs are a great pest if the spring proves wet, and a few plants should be kept in reserve to make up blanks. Cinder ashes, sand, and various other things which slugs do not relish, may be spread over the soil round each plant to help to check their work; but to catch them and kill them is probably the best way of saving the plants.

Where the ground is exposed to the north and east, it is a good plan to stick in a stiff sprig or two of evergreen on those sides of each plant, to protect them from cutting winds, which often prevail at that season. As they progress in growth they must be attended to by drawing a little soil to them, to keep them from becoming loose at the neck; and, if dry, a good watering should be given before they are moulded up.

To make sure of succession, I have frequently planted some of these potted plants on a north border, and found them come in very handy, especially when the season proved hot and dry.

About the middle of February, a sowing should be made in heat to succeed the autumn-sown plants. The temperature should be from 55° to 60° till they come up; then they should be removed to a dry cold pit or frame and placed near to the glass, and when about 2 inches in height pricked off into rich soil in a cold frame. Here they are completely protected from any frost that may occur, but otherwise hardily reared. These make fine strong plants by May, ready to be planted out. They should be lifted with good balls, and carefully planted and attended to with water should the weather be dry, till they get a good hold of the soil. For summer plantations a good, holding, well-manured and worked, loamy soil is the best; and in dry sandy soils it is most difficult to prevent a great bulk of the crop from buttoning if the season prove dry.

To succeed this sowing made in heat, I have usually found it desirable to make another under hand-glasses on a wall border about the middle of March, and afterwards at intervals of three weeks, up to the middle of June. The plants should always be pricked-out into beds of rich soil as soon as they can be conveniently handled, and before they become drawn in the seed bed. They suffer less from the transplanting when young than if it be delayed till they form deeper tap-roots. From the time they are pricked-out till they are established in the garden quarters, they must never be allowed to get a check from want of water, for if once they become "blue," there is little chance of their doing well afterwards. This frequent sowing, and as frequent planting, is the only way to be sure of keeping up a constant succession of nice heads, fit to present in the dining-room. It is not necessary to make large plantations, except in the case of the last for the season, from which a winter supply is expected at least up to Christmas. The last should, therefore, be the largest of the plantings, as it comes in at a cool season, when the heads stand long in good condition, and can be stored away to keep in quantities.

The time for making the last sowing and planting will require always to be determined by the climate of different localities. Here the latest may be delayed till August, but in most places in Scotland it will require to be planted somewhat earlier. By the time the latest is consumed, it is succeeded by that excellent variety of Broccoli, known by the name of Snow's Winter Broccoli, easier known by name than by experience, although I always manage to obtain it true.

In light dry soils I have found it a good plan, to make sure of good Cauliflower, in very dry seasons, to plant a few rows among rows of Peas, kept rather wider apart than is common. The Peas afford shade to the plants, and I have seen them do well when they buttoned extensively in open quarters. The later, and particularly the latest, should always be in well-exposed situations. It is a practice in England to take two crops of Cauliflowers from the same ground. When those planted in April in an open quarter are cut, which is generally by the 1st of July, I have frequently trenched or dug the ground and planted again, and had two good crops in the same place. The latest planting has generally succeeded the earliest sowing of Kidney Beans and second-early Potatoes.

In keeping up a constant supply of this vegetable, one of the most necessary auxiliaries is a cool, dry, dark cellar, with its floor, or part of it at least, covered 6 inches deep with moist sand. When Cauliflower comes in quicker than it can be used, it should be cut—when scarcely so big as is desired for table—with half a foot of the stem attached, the leaves cut off square with the surface of the flower, and then stuck into the sand in the cool dark place. In this way they keep crisp for weeks; and for saving the late crop when frost sets in, it is a plan much preferable to that of hanging them up in sheds with the leaves and stumps attached; and late in the season particularly, it is surprising how long they keep in good condition.

As to the best kinds of Cauliflower for different seasons, I think, if I had to confine myself to one sort, I would choose the Walcheren. For a summer variety probably the New Frogmore is preferable, inasmuch as it stands longer without opening or running than the Walcheren. These two, with the Early London, are the varieties I confine myself to. About fifteen or perhaps more years ago, there was a sort grown about London as Myatt's Cauliflower, which to my mind was the best I ever saw, but have not seen it true for a good many years.—D. Thomson (*The Gardener.*)

GARDENERS' ROYAL BENEVOLENT INSTITUTION.

The twenty-sixth anniversary dinner of this Institution took place at the London Tavern, Bishopsgate Street, on the 23rd of June. The Duke of Argyll, K.T., took the chair, and was supported by G. F. Wilson, Esq., F.R.S.; J. Bateman, Esq., F.R.S.; Professor Owen, A. Helps, Esq., R. Wrench, Esq., and J. J. Mechi, Esq. Among the company, which was more than usually numerous, were Mr. John Lee, Mr. Charles Lee, Mr. Williams, Mr. Carmichael, of Sandringham Gardens, Mr. Eyles, Mr. Earley, Mr. Forsyth, Mr. Holmes, Mr. Judd, Mr. Marnock, and Mr. Taylor.

The Chairman, in proposing the health of Her Majesty, dwelt at some length on the interest which she takes in plants, especially in those which flourish on alpine summits, where Nature, as if to compensate for the fewness of her gifts, had given the flowers such exquisite delicacy and beauty. And he related that only three weeks ago Her Majesty had asked him if he remembered the name of a flower which she had brought home in one of her Highland excursions, and he was sorry to say he did not, but Her Majesty showed him the whole collection of dried specimens of the plants of Braemar; he examined them, and he believed he was correct in stating that the plant was Azalea procumbens. He mentioned this to show the interest Her Majesty takes in botany.

After the other loyal and patriotic toasts, the Chairman, in proposing the toast of the evening, "Prosperity and Success to the Gardeners' Royal Benevolent Institution," said he well knew there were present those who were better acquainted with its objects and operation than himself, but the object was to provide retiring allowances or pensions to gardeners, market gardeners, nurserymen, and their widows, to make them comfortable in their old age. He rejoiced to say that it was not one of the conditions attached to the pension that the recipients should live immured in buildings, but they could live with their friends, and in this way a comparatively small sum sufficed to make them comfortable. The rule by which preference is given to those who have subscribed for fifteen years so long as any such are candidates for election, was commended as being very judicious. And then, referring to the mode in which the funds are raised, it was remarked that they are partly derived from gardeners themselves, but still more largely from others; but if all the working gardeners in this country were to subscribe, the funds would be more than sufficient. Nothing had surprised the public more than the large sums of money which had been subscribed by trades' societies throughout the country, showing what could be done by a long pull, a strong pull, and a pull all together. But bricklayers, carpenters, and other trades were chiefly gathered together in the great centres of industry, while gardeners have been under great disadvantages in this respect from shunning these centres, and especially the chimnies. From being thus scattered in remote districts, gardeners had some difficulty in providing for themselves funds for their maintenance in sickness and old age; at the same time he would earnestly recommend the adoption of some more ample system of organisation for the purpose. Referring then to the market gardeners, he knew nothing more wonderful than how London's 3,000,000 of population were provided with fruit and vegetables—a population exceeding that of many of the most powerful states of ancient history. One had only to walk out on a hot summer's evening, and he

would see hundreds of waggons coming into that greatest of all gardens in the world—Covent Garden; and even Penzance sent to it early Broccoli and early Potatoes, and the tropics their fruits. No country in the world was supplied with such fine fruit as this, and he even believed that the table of the Emperor of the French was supplied with it from this country. So with flowers. He, the Chairman, had had no wish so great as to see the flowers in the tropics—he supposed he never should, but he was somewhat reconciled to that on reading the remarks in Mr. Wallace's "Malay Archipelago." Individually the flowers of the tropics were magnificent; but as regards colouring the landscape, they were not so effective as the flowers of the temperate regions—the Heather on our mountains, the Hyacinths of our woods, and the flowers of our pastures. Besides the flowers of our own temperature, those of other regions had been brought together and cultivated successfully. These were great triumphs of skill, great triumphs of industry, and the gardening of this country was one of the greatest triumphs of civilisation. After referring to the refining influence of flowers, the Chairman concluded by calling on his hearers to cultivate the gardener's art, and to show their interest in that class of men to whom society owes so much.

Among the other toasts were "Physiological Science," coupled with the name of Professor Owen; "The Chairman;" "The Horticultural and Botanical Societies," responded to by Mr. Bateman; "The Treasurer," responded to by Mr. Wrench; "The Secretary;" and "The Nursery and Seed Trade," coupled with the names of Mr. Veitch and Mr. Hurst, the latter of whom returned thanks.

As usual there was a tastefully arranged group of plants at the back of the chair, also plants and cut flowers on the tables and in other parts of the room. These were contributed by Messrs. Veitch, Lee, Williams, and Turner; while fruit for the dessert was sent from the gardens of His Royal Highness the Prince of Wales, Baron Rothschild, and Mrs. Dixon, of Stanstead Park.

The list of donations amounted to nearly £500.

ROYAL HORTICULTURAL SOCIETY.

Rose Show, *June* 29*th*.—More favoured by weather than its predecessor at the Crystal Palace, this exhibition, with which is incorporated the National Rose Show, was eminently successful in the number of stands exhibited, the quality of the flowers, and in the numbers who flocked to this the great levée of the queen of flowers. There were, as there always are, a good many defective blooms; there were, as there always are, a good many stands which might have been set up to much better advantage; but on the whole there was an absence of coarseness, a refinement of form, and a beauty and freshness of colour, which gave it a peculiar charm. Larger blooms of many of the kinds have been shown, and not a few had changed colour under the influence of the hot sun of the past week, but taken all in all this was the Rose show of the season—a season hitherto in some respects as remarkable as that of 1868.

In Class I, seventy-two single trusses, Messrs. Paul & Son were first with a splendid collection, in which we remarked as fine—La Ville de St. Denis, Exposition de Brie, Clotilde, Maréchal Vaillant, Marie Baumann, very large and fine, but showing the eye a little; Pierre Notting, Dr. Andry, Marguerite de St. Amand, Le Rhone, Comtesse de Chabrillant, Antoine Ducher, Baroness Rothschild, Charles Lefebvre, Alfred Colomb, Victor Verdier, Camille Bernardin, Xavier Olibo, Mdlle. Marie Rady, Duchesse de Caylus, Pitord, Maréchal Niel, Senateur Vaisse, Leopold Premier, Madame Victor Verdier, Madame Thérèse Levet, Beauty of Waltham, Felix Genero, Devienne Lamy, new; Triomphe de Rennes, Maurice Bernardin, Centifolia Rosea, François Treyve, extremely brilliant; Thorin, Jean Cherpin, and Madame Willermoz. Mr. Turner came second, with a lot but little inferior, containing beautiful examples of Souvenir de Monsieur Boll, Horace Vernet, Rubens, Felix Genero, Souvenir de Comte Cavour, Général Jacqueminot, Abel Grand, Napoleon III., darkly shaded; Marie Baumann, Prince Camille de Rohan, Rev. H. Dombrain, Narcisse, Madame Victor Verdier, Marguerite de St. Amand, John Hopper, Gloire de Dijon, Maurice Bernardin, Duchesse de Caylus, Madame Charles Wood, and Triomphe de Caen. Mr. Keynes, of Salisbury, who was third, had fine blooms of Duchesse d'Aoste, bright rose; Marguerite de St. Amand, Victor Verdier, not large but beautifully fresh; Marie Baumann, Alba mutabilis, Souvenir de Malmaison, Madame Vidot, Coquette des Alpes, white; Dr. Andry, Duc de Rohan, Lord Macaulay, Elie Morel, Abel Grand, and good examples of several others. The fourth prize went to Messrs. Francis, of Hertford, for stands which included good trusses of several of the varieties already named.

Class 2 was for three trusses of forty-eight varieties. In this the first prize went to Messrs. Paul & Son for magnificent specimens of Leopold Hausburg, Duchesse de Caylus, Madame Clemence Joigneaux, Duke of Edinburgh, Madame Fillion, Marguerite de St. Amand, Souvenir d'Elise, Senateur Vaisse, Mdlle. Thérèse Levet, Horace Vernet, Xavier Olibo, Beauty of Waltham, Exposition de Brie, Maréchal Niel, Comtesse de Chabrillant, Antoine Ducher, Charles Lefebvre, Camille Bernardin, Abel Grand, Paul Verdier, Triomphe de Caen, Maurice Bernardin, Marie Baumann, John Hopper, Alfred Colomb, Madame Caillat, and Prince de Portia. To Mr. Keynes the second prize was awarded for stands containing fine trusses, among which the following were conspicuous:—Louise de Savoie, Marguerite de St. Amand, Exposition de Brie, Madame Sertot, Duchesse d'Aoste, Madame Vidot, Victor Verdier, Madame Canrobert, John Hopper, Charles Lefebvre, and Paul Verdier.

The third prize went to Mr. C. Turner, who had fine examples of Exposition de Brie, Charles Lefebvre, Beauty of Waltham, Souvenir de Comte Cavour, Gloire de Dijon, John Hopper, Madame Victor Verdier, Marie Baumann, Général Jacqueminot, Alfred Colomb, Duke of Wellington, Madame Clemence Joigneaux, Vicomte de Cazes, and Maurice Bernardin. The fourth prize was taken by Messrs. Francis, John Hopper, Charles Lefebvre, Gloire de Dijon, Jules Margottin, Colonel de Rougemont, and Mdlle. Bonnaire, were the most conspicuous in this collection.

The next class was for three trusses of twenty-four kinds, and though not so effective, was everything that could be desired as regards quality. Messrs. Paul & Son were again successful in taking the first position with Marguerite de St. Amand, Baroness Rothschild, John Hopper, brilliant; Beauty of Waltham, Maurice Bernardin, splendid; Senateur Vaisse, Madame Noman, Duke of Edinburgh, very fine, and rich in colour; Marie Baumann, Madame Rivers, Abel Grand, La France, Lord Clyde, and Mdlle. Thérèse Levet. Mr. Turner came second with Madame C. Joigneaux, John Hopper, Leopold Hausburg, Victor Verdier, Madame Victor Verdier, Paul Verdier, Impératrice Eugénie, Marguerite de St. Amand, Felix Genero, Marie Baumann, and Exposition de Brie, besides others likewise very good. The third prize went to Mr. Keynes, who had very good examples of Victor Verdier, Marie Baumann, Duchesse d'Aoste, Madame Vidot, Dr. Andry, Madame Beanverger, Alfred Colomb, John Hopper, Madame Rothschild, Marguerite de St. Amand, Beauty of Waltham, and Comtesse de Chabrillant. Mr. Cranston, King's Acre, Hereford, was fourth with, among others, very large trusses of Marguerite de St. Amand, Felix Genero, Jules Margottin, and Monsieur Noman. Mr. Fraser, of Lea Bridge, sent Le Rhone, Exposition de Brie, John Hopper, and Leopold Hausburg, very beautiful both in form and colour.

In the nurserymen's class for single trusses of twenty-four varieties, Mr. Cant was first with splendid specimens of Marie Baumann, Baronesse de Rothschild, Madame Willermoz, Maréchal Niel, Maréchal Vaillant, Céline Forestier, Madame Bravy, Duchesse de Caylus, Souvenir d'un Ami, Xavier Olibo, and Marguerite de St. Amand. Mr. Keynes was second with Viceroy, a new purplish kind with a brighter centre, Felix Genero, Abel Grand, John Hopper, and several others equally good. Mr. Turner was third with a very good stand, and Mr. Cranston fourth.

In the amateurs' class for forty-eight varieties there were several excellent exhibitions, particularly that from Mr. Chard, gardener to Sir F. Bathurst, Bart., Clarendon Park, Salisbury, who gained the first prize. In this were excellent trusses of Marie Baumann, Mdlle. Bonnaire, Maréchal Niel, Madame Boutin, Madame Moreau, Duc de Rohan, Fisher Holmes, Duchesse de Caylus, John Hopper, Maréchal Vaillant, Pierre Notting, Exposition de Brie, Maurice Bernardin, Souvenir d'un Ami, and Céline Forestier. The second prize went to Mr. A. Moffat, gardener to the Earl of Rosslyn, Easton Lodge, Dunmow, who had fine specimens of Maurice Bernardin, Maréchal Niel, John Hopper, Madame V. Verdier, François Lacharme, Moiret, and Rubens. Mr. Ingle, gardener to Mrs. Round, Birch Hall, Colchester, was third with fine trusses of Exposition de Brie, Rubens, Madame Caillat, Jules Margottin, Maréchal Niel, Maréchal Vaillant, La Brillante, Senateur Vaisse, La France, and Jules Margottin. Mr. Exell, gardener to J. Hollingworth, Esq., Maidstone, was fourth, who, as well as Mr. Laxton, of Stamford, had in his stands excellent blooms of Maréchal Niel, Alfred Colomb, Madame Victor Verdier, Marie Baumann, Senateur Vaisse, Victor Verdier, and La France. Mr. Johnson, of Uxbridge, would have been second if he had not had two blooms under the name of La Brillante. Of his others several were very bright-coloured and fine, especially Madame Victor Verdier, Senateur Vaisse, Madame Caillat, Mdlle. Thérèse Levet, Narcisse, Victor Verdier, and Duc de Rohan.

In Class 6, for thirty-six varieties, there were several very fine exhibitions. The first honours went to Mr. Chard, who had admirable blooms of Olivier Delhomme, Thorin, Duchesse de Caylus, Dr. Andry, Xavier Olibo, Maurice Bernardin, Narcisse, Maréchal Vaillant, Lord Macaulay, Madame Knorr, Comtesse de Chabrillant, Madame Boutin, John Hopper, Madame Charles Crapelet, Rubens, and Maréchal Vaillant. Mr. Ingle, gardener to Mrs. Round, was second with Charles Lefebvre, Charles Lawson, Madame Domage, Jules Margottin, Lord Raglan, Maréchal Niel, &c.; and Mr. Stoddart, gardener to J. G. Rebow, Esq., M.P., Wivenhoe Park, third; Mr. A. Moffat being fourth, and an extra prize was awarded to Dr. Cooper, of Slough.

The class for twenty-four single trusses brought very good exhibitions from Mr. Cant, Myland Lodge, Colchester, and Mr. Stoddard, who were first and second. Among the kinds shown were excellent trusses of Fisher Holmes, Marie Baumann, Merechal Niel, Comtesse de Chabrillant, Dr. Andry, La Ville de St. Denis, Souvenir de Charles Montault, Maréchal Vaillant, John Hopper, Victor Verdier, Mdlle. Bonnaire, Jules Margottin, and Charles Margottin. In Mr. Cant's collection every bloom was good. Mr. Exell was third; Mr. Stretton, Manningford, fourth; and an extra prize was awarded to Mr. Soder, gardener to O. Hanbury, Esq.

For twelve trusses Mr. Cant was again first with fine examples of Pauline Lansezeur, John Hopper, La Ville de St. Denis, Cloth of Gold, Marie Baumann, Maréchal Niel, George Prince, Charles Le-

febvre, and Madame Clemence Joigneaux. Mr. Soder was second, Mr. Marsh and Mr. Quinnell third, and Mr. Stretton fourth.

For eighteen new Roses of 1867 or 1868, which will be reported on by "D., *Deal*," the prizes went to Messrs. Paul & Son, Mr. Keynes, Mr. Cant, and Mr. Turner, in the order named. Mr. Cant, of Colchester, was first for twelve trusses of any new Rose of 1867 with La France, Mr. Keynes second with Elie Morel. The first prize for the best six trusses of any new Rose of 1868 was awarded to Messrs. Paul and Son for Duke of Edinburgh, the beauty and brilliancy of which were noticed last week in connection with the Crystal Palace Show.

Yellow Roses, however charming in themselves, when unmixed with other brighter-coloured varieties exhibit a great amount of sameness. The first place for the best twelve was taken by Mr. Cant with Vicomtesse de Cazes, Gloire de Dijon, Triomphe de Rennes, Maréchal Niel, Climbing Devoniensis, and Céline Forestier, all of which were in fine condition. Mr. Stoddart came second with Maréchal Niel and Triomphe de Rennes, both finely coloured, Solfaterre, Gloire de Dijon, and Madame Falcot; Mr. Keynes being third, and Mr. Chard fourth. In the class for the best exhibition of yellow Roses of one or more varieties, Mr. Cant was first with a splendid group of Maréchal Niel, Céline Forestier, very fine, Triomphe de Rennes, Madame Falcot, and Safrano. Mr. Stoddart was second, and Mr. Chard third.

The classes for twelve Tea-scented and Noisette Roses drew together several very pretty collections. Mr. Cant took the lead among nurserymen with beautiful examples of Madame Bravy, Maréchal Niel, Niphetos, Souvenir d'un Ami, Rubens, Gloire de Dijon, Madame Willermoz, Céline Forestier, Triomphe de Rennes, and Marquise de Foucault. Messrs. Paul & Son were second with excellent specimens of several of the above, Reine du Portugal, new, and Lamarque. Mr. Keynes, who was third, had Madame Sertot, very large and fine, Moiret, Sombrieul, and others already named. In the amateur's class Mr. Ingle, who was first, had fine trusses of Madame Bravy, Gloire de Bordeaux, Maréchal Niel, Madame Margottin, Gloire de Dijon, Devoniensis, Rubens, Bougère, Souvenir d'un Ami, and Sonvenir d'Elise. Mr. W. Cant, of Myland Lodge, Colchester, who was second, had, besides fine examples of Maréchal Niel and Adam, very good ones of Souvenir d'un Ami, Pauline Labonté, Devoniensis, Gloire de Dijon, Triomphe de Rennes, Madame Bravy, Céline Forestier, and Cloth of Gold. Mr. Stoddard was an excellent third.

In the open class for single blooms of twelve varieties, the first prize went to Mr. Cant, nurserymen, Colchester, for a remarkably fine stand containing Souvenir d'un Ami, Colonel de Rougemont, Marie Baumann, Maréchal Niel, beautifully coloured; Duc de Wellington, Marguerite de St. Amand, La Ville de St. Denis, Madame Bravy, Le Rhone, and Gloire de Vitry. Mr. J. Keynes, who was second, had Souvenir d'on Ami, Monsieor Noman, Soovenir de Malmaison, Pitord, Elie Morel, Victor Verdier, Marie Baumann, very bright and beautiful; Louise de Savoie, Marguerite de St. Amand, and Devoniensis. The third-prize lot came from Mr. Turner, and contained Caroline Hole, a seedling with, as shown, a salmon-rose centre and purplish pink towards the outside; Antoine Ducher, Rubens, Monsieur Noman, Gloire de Dijon, and others less noteworthy. Mr. J. Cranston, who was fourth, had Marquise de Mortemart, pretty pale rose.

Prizes were offered for vases or baskets of Roses, but brought no novelty in design. Mr. Soder was first with a March stand with Ferns and Roses at the base, Japanese Honeysuckle twining up the stem, and Roses, Pteris, and Maidenhair Fern in the top dish. Mr. Chard was second with a similar stand, having Cissus discolor twined up the stem, and ornamental grasses freely introduced.

Prizes were also offered for six bouquets of distinct kinds, five trusses of each. Mr. Cant, nurseryman, of Colchester, was first with beautiful examples of Le Rhone, Céline Forestier, Marie Baumann, Souvenir d'Elise, Charles Lefebvre, and Margnerite de St. Amand. These were set up in Etruscan terra-cotta vases, and surrounded with bouquet paper. Messrs. Paul & Son were second with John Hopper, Dr. Andry, Marguerite de St. Amand, Senateur Vaisse, Céline Forestier, and Charles Lefebvre, set up in Hyacinth-glasses. Mr. Chard was third.

Of Moss Roses only two stands were shown, the exhibitors being Messrs. Paul & Son and Mr. Cranston. There were in these trusses of Baronne de Wassenner, the Common, which still maintains its place as one of the best, Angélique Quetier, Celina, Laneii, &c.

Of Roses in 8-inch pots, the admirably-grown plants from Messrs. Paul & Son were first. The following were especially remarkable for the profusion of bloom—viz., Duchesse de Caylus, Souvenir de Malmaison, Charles Lefebvre, Dr. Andry, Louise Margottin, Lord Clyde, Senateur Vaisse, Général Jacqueminot, Triomphe de Soissons, Leopold Hausburg, and Louise Odier. Mr. Turner, who was second, had also most excellent plants, Maurice Bernardin, John Keynes, Maréchal Vaillant, Duchesse de Caylus, and Madame Alfred de Rougemont were particularly worthy of mention. Messrs. Francis, were third. The first prize for new Roses in pots went to Messrs. Paul & Son.

The miscellaneous subjects were not numerous, Mr. W. Paul sent his new Roses, Prince Leopold and Princess Christian. Phlox Beautiful, and Blue Bell and other Pelargoniums, including Waltham Bride, with white-variegated leaves and white flowers. Mr. Postans, of Brentwood, sent fifty splendid blooms of John Hopper Rose; Mr. Hooper, Widcombe Hill, Bath, Pinks, both show and bedding, Picotees, and Pansies; Messrs. F. & A. Smith, Tricolor and Bicolor Pelargoniums; Mr. Mann, Brentwood, flowering and Tricolor-leaved Zonal Pelargeniums; Mr. Turner, Blue Gown Cucumber; and Monsieur Baulant his beautiful artificial flowers and plants noticed in the report of the Floral Committee of June 15th.

ROYAL BOTANIC SOCIETY'S SHOW.

This Society's last Show for the season commenced yesterday, and will be continued this day. For this time of year there is a great amount of freshness and beauty in the plants exhibited, which, as usual, are very numerous, but fruit forms its distinctive feature. Mr. Miller, gardener to Lord Craven, Combe Abbey, carries off the first prize for the best collection with two handsome Queen Pine Apples, splendid bunches of Black Hamburgh Grapes, Foster's White Seedling Grapes, two Melons, Royal George Peaches, very large and fine, Elruge Nectarines, and British Queen Strawberries. Mr. Bannerman, gardener to Lord Bagot, Mr. Johnson, Mr. Miles, Mr. Simpson, of Wortley, and Mr. Carmichael, gardener to the Prince of Wales, have also good collections. The last-named exhibitor has in his collection two fine Melons, named respectively the Prince and Princess of Wales, the former green-fleshed, the latter scarlet-fleshed, and large bunches of Black Hamburgh Grapes, which had become much rubbed in carriage. Mr. Douglas, Loxford Hall Gardens, stands first for Black Hamburgh Grapes, with beautifully coloured compact bunches; and Mr. Bannerman and Mr. Henderson, Colcorton, send fine bunches of the same kind. The best Muscats come from Messrs. Standish & Co. Mr. Bannerman and Mr. Goldsmith send very good Black Prince; Mr. Cole, Ealing Park, and Mr. Douglas, Buckland Sweetwater, the bunches from the former being especially good; Messrs. Standish and Co. baskets of the Royal Ascot, finely coloured, and Vines of the same Grape trained with a flat head, bearing excellent bunches. Among baskets of Grapes, however, the lead in Black Hamburghs is taken by Mr. Miller, in Muscats by Mr. Davis, of Fryern Barnet. Mr. Henderson also sends Black Mammoth Grape, an Australian seedling, with very large oval berries. Peaches and Nectarines on the whole are rather small. Mr. Jack, gardener to the Duke of Cleveland, Battle Abbey, has Bellegarde, very large, and Mr. Miller, Grosse Mignonne, very fine. Pine Apples are few in number, and not remarkable for size. Mr. Ward, gardener to T. N. Miller, Esq., Bishop Stortford, has a fine Prickly Cayenne, of 5¼ lbs., an excellent Queen of 4½ lbs.; and Mr. Bailey, of Shardeloes, a large Providence and a fine Queen.

Orchids from Messrs. Williams, Parker, Hill, and Wheeler are remarkably good, whilst the collection of eight from Mr. Archer, gardener to A. Turner, Esq., Leicester, is worthy of all praise. In this there is a fine mass of Cypripedium barbatum superbum, Odontoglossum Pescatorei, Phalænopsis grandiflora, and Saccolabium guttatum with ten spikes, all of which plants are splendid specimens. Mr. Wilson, gardener to W. Marshall, Esq., who is second in the same class, sends Cypripedium Stonei with six flowers, four of which are on one spike, and a beautiful specimen of Dendrochilum filiforme. Mr. Lawrence, gardener to the Bishop of Winchester, has a plant of Trichopilia turialvæ, with a regular ring of blossoms, a beautiful specimen of this recent introduction. New plants are exhibited in multitudes by Messrs. Veitch, Bull, Williams, and Henderson of Wellington Road and Pine Apple Place. Of cut Roses, too, there is a large exhibition, furnished by Messrs. Paul & Son, Mitchell, Turner, Fraser, Hill, Exell, and others; and a magnificent display of Roses in pots from Messrs. Paul & Son.

ASPECTS OF SPRING GARDENING.—No. 3.

My third aspect of spring gardening is drawn from a source much further northward than I have as yet taken your readers—away from the "precincts of the silver sea," and the softer climate of the southern shores of England—to a district different in almost every respect from that I have previously drawn my supplies from, save this, that there, as in the south, spring gardening is well carried out; but in this instance to such an extent as to astonish, and with such excellent results as to delight, those who yearly search the country through for illustrations of this somewhat modern feature of gardening.

The scene is laid at the gardens of the Holte Hotel, Lower Grounds, Aston, Birmingham. The proprietor of these grounds is a spirited and genial man, wonderful in resource, and prompt and decided in action, by name Mr. H. G. Quilter. Some few years ago (having, as the manager of the Aston Park Estate under the corporation of Birmingham, obtained some insight into the recreative requirements of a great industrial community), he became the proprietor of about 36 acres of the Lower Grounds of the Aston Park Estate, with the idea of making it a place of popular resort and recreation. His design was to provide for the masses of population who inhabit Birmingham, sources of recreation that while they should be broadly applicable to the varying tastes of an enormous community, should also exclude every coarse feature which would be likely to wound the sensibilities of the most fastidious social reformer. This, by dint of untiring energy, he has established in one of the immediate suburbs of Birmingham, scarcely more than two miles

distant from the busy centre of this vast iron metropolis: and by means of lakes for boating and fishing (one being exclusively retained as an ornamental water for various species of waterfowl, &c.); by providing archery, cricket, and croquet grounds, and extensive bowling greens; by high-class concerts, by private theatricals and dancing under the strictest regulations; by the daily attendance of a first-class band of music; and lastly, and not least in the category of attractions, by the introduction on an extensive scale of the best modern features of spring, summer, and subtropical gardening, combined with shady walks under umbrageous trees, grass plats, specimen ornamental trees, clumps of Rhododendrons, &c.—Mr. Quilter has become related to Birmingham in such a beneficent social bond as to secure the full approbation of the lover of his kind, and the admiration of the practical horticulturist.

The whole grounds are irregularly pyriform in shape, the dwelling-house forming the apex, the large boating lake the reverse of the outline. While they may be roughly divided so, next the dwelling-house are the grass lawn and ornamental water; then a walled-in garden of four acres used as an extensive flower garden, on the left of which are the archery, cricket, and other grounds. Beyond this come the promenade and the boating lake. A broad gravel walk 300 yards in length leads down to the walled-in garden and recreation grounds. On the right is a large stretch of grass plat, with the ornamental water parallel with it; on the left a verge of grass lawn, with a broad flower and shrubbery border skirting the Harborne Road. Right and left of this broad walk there is a line of oblong and circular beds alternately, the one filled with hardy evergreen shrubs, the other with spring flowers, such as Tulips, Iberis sempervirens, and such like. The grass plat on the right falls with a gentle declivity towards the lake, and about it are studded various specimen Coniferæ, while a line of golden Thuja aurea skirts a narrow gravel path running parallel with the lake. The broad flower border in front of the line of shrubbery on the left presented a striking floral spectacle. The flower border proper is about 6 feet in width. Next the shrubbery comes, as a kind of floral background, a line of herbaceous Phloxes alternately with Dahlias; in front of this dwarf Roses and herbaceous Pæonies alternate, leaving a space of about 4 feet to fill in with bedding plants, a sharply angled zigzag line of single and double Tulips, early and late-blooming kinds being mingled together for the purpose of prolonging the effect. The groundwork of this bed was formed of slanting diamonds of Viola cornuta and Cerastium tomentosum, each diamond filling up two angles formed by the line of Tulips. As this border falls gently towards the lower portion of the ground, the visitor appeared to be looking along a broad band of Tulips instead of a zigzag line simply. At the extremity of the broad walk, and on the right of the same, and forming a fine and attractive object when seen from the distance, was a huge raised circular bed about 1 foot from the ground, the pedestal formed of turf banks. From the centre of this circle sprang two baskets, the one appearing to issue from the other. The space round the lower basket gave a circular border 6 feet in width, admitting of nine circular lines of Tulips, the back and the front circles being mixed double and the others mixed single flowers. This was broadly edged with Cerastium tomentosum just coming into bloom. The baskets were formed of pieces of the outside wood and bark of the Fir held together by cables. This basket was filled with Golden Prince early single Tulip and Wallflowers, edged with Stachys lanata. The upper basket was also filled and edged in a similar manner. Between the lake and the enclosed flower garden was a piece of ground which had been prepared as a subtropical garden; while on the other side of this garden, close by the promenade, are other beds to be used for the same purpose. Many other nooks and corners and raised beds, together with rustic baskets, are also utilised. There are also introduced cascades, waterfalls, &c., all of which considerably heighten the effect sought to be produced, and impart a finish to the whole arrangement.

So far I have only touched on what lies outside the area of the great floral display within the enclosed garden. It is that I will now attempt to pourtray, aided by the accompanying plan, though the best my pen can perform would give but an inadequate conception of the splendid effect produced here. The walled-in garden is nearly four acres in extent, and is laid out in the form of a huge Maltese cross, the arms of the cross being represented by a broad raised border on either side, with a broad gravel walk between. The centre of this garden, which forms the body of the cross, is of a circular shape, and the exterior border on the plan gives one-half of the raised border just referred to. The scale being 15 feet to 1 inch, some idea of the extent of the central garden alone can be obtained. The four openings in the outer border represent the main walks forming the arms of the cross, running the length and breadth of the garden from east to west and from north to south, halfway between the wall enclosing the garden and the central garden as given in the plan. Each arm of the cross expands in order to admit a large oval bed, on either side of which runs the broad gravel walk. Under the four walls forming the boundary of the garden there are broad borders, and at the angles huge banks of Hollies, Rhododendrons, &c., with backgrounds of Coniferæ. A broad gravel walk divides these borders from the square occupied by the cross and the angles of grass plats which fill up the outline of the garden. About these angular grass plats are studded ornamental trees and shrubs, rustic baskets, and various flower beds. The raised border on either side of the central gravel walks thus faces both ways—to the gravel walks, and also to the grass plats in the angles of the garden. A Yew hedge about 4 feet in height occupies the apex of the raised border throughout, with standard Roses at short intervals in a line with the Yews. When the central garden is reached a background to the Yew hedge is introduced in the form of a galvanised iron fence in perpendicular lines, hollowed out at the top at intervals to give the form of hanging in festoons. These festoons spring from standard plants of Acer Negundo variegatum, the ends of the convex festoons meeting just under the silvery head of foliage, and being supported thereby. The line of circles on the exterior of the accompanying plan gives the sites occupied by the variegated Acers. The finest edge of this border, here in a level with the gravel walk, is edged with turf. Next this is a broad circular gravel walk, as seen in the plan, then a scroll bed inlaid in turf, then a sharp fall of some 5 feet leads to a sunken panel garden, in the centre of which is a fountain. So much for the general outline of the grounds, and disposition of the beds. The galvanised iron fence on each division of the outer border, is continued across the gravel walks, dividing them by means of lofty and handsome wire arches, from the centre of which, and immediately over the centre of the walk, hangs an ornamental basket in wire, which, during the summer months, is filled with flowering plants. Hops, climbing Roses, Clematises, &c., run over these arches, and form conspicuous and attractive objects when viewed from any distant point. At the corners next the central walk, and corresponding to the corners from which the ornamental wire arches spring, are placed stone vases on pedestals, filled in the spring months with Tulips, Dielytra spectabilis, &c., and in the summer months with showy flowering and foliaged plants.

The lines running from front to back in the outer border, as seen in the plan, represent divisional rows of dwarf Spruce Firs, about 12 inches in height. These remain here constantly, and are kept clipped at intervals to keep the line dwarf and regular. The panel with double lines in each division so formed, is also formed of two lines of Spruce Firs. These, however, are removed when the summer-bedding plants are placed out. This circular border is about 10 feet in width, and rises from a level with the gravel walk to a height of nearly 3 feet at the apex, in which is planted the Yew hedge. Inside the double line of Spruce Firs was a line of the variegated Arabis next the Firs, the space between filled up with double crimson Daisies. The groundwork outside the Firs was filled with Stachys lanata, with the exception of the rounded angles, which were masses of Aubrietia purpurea. Each bed was planted in the same manner, with the exception of the centres in this respect, a mass of the blue Forget-me-not, with which was mingled a pretty pale-striped single Tulip, alternated with a mass of the pink Silene pendula, with which was mingled a showy double crimson Tulip.

The scroll bed in the inner side of the walk was one of the finest features I have ever beheld in the way of spring gardening. It was a chaplet of various colours, inlaid on the emerald turf. In length, this border is upwards of 90 yards, in width about 5 feet. It was almost wholly planted with Daisies, and it required 7000 to work out the design, independent of the other plants employed. The serpentine line in the plan represents a broad line of the double crimson Daisy; the groundwork of the bed occupying the rounded angles was composed of double white Daisies. On either side of the crimson serpentine band were lines of Echeveria secunda. The line of circles next the walk were composed of rings of Viola cornuta on the outside, then a ring of pink double Daisy encircling a centre clump of the crimson-foliaged Ajuga reptans. The

circles on the fountain side were formed thus:—An outer ring of the golden-blotched double Daisy, an inner ring of Aubrietia purpurea, and a central clump of the Ajuga as before.

Passing down the turfy slope, the sunken panel garden is reached, composed of four beds, in shape resembling the divisions of a circular line, and four small circular beds, in which was a pedestal of "slag," a blue-tinted deposit left in the manufacture of glass, supporting a stone vase. These vases had previously been filled with vari-coloured Hyacinths, but had now as occupants large plants of Centaurea candidissima. Round the base of each pedestal of slag was a row of Echeveria secunda. The four other beds were also edged with this useful plant, and filled with bright masses of Silene pendula, mingled with which were showy Tulips of various colours. The fountain is within a stone basin, the edge of which is level with these beds. There is also a border round the stone basin, having, as a background, a circle of the common Fern, then a band of Wallflowers mingled with double crimson and double yellow Tulips, the whole edged with showy gold-laced Polyanthuses.

I have attempted to pourtray this "floral scene," but to appreciate it, it is necessary to look upon it. The numberless details, all of them skilfully wrought out, cannot be described even in the somewhat large space this paper will require. I must, however, make allusion to a broad border, some 10 feet in width, under the wall on either side of the garden, along the side of which runs a broad gravel walk. The wall is covered with fruit trees, and in front of these, as a background to the

flower border, but allowing of a narrow walk between it and the fruit trees, is a hedge of dwarf Roses that bloom the summer through. This flower border represents a chain of diamonds formed by the use of the dwarf Spruce Fir. On two sides of the garden these diamond beds were filled with the blue and white Forget-me-not and Silene pendula alternating; and on the two other sides the beds are planted with Cliveden Blue, White, Yellow, and Purple Pansies alternating. The angles formed by the diamond beds are all filled with Cerastium tomentosum, which comes into full bloom by the time the spring flowers are at their best, and when the bloom is past it is clipped with sheers, and does admirable service all the summer as an ornamental-foliaged plant. Probably no one can realise sufficiently the value of the Cerastium as a bedding plant but those who have seen it growing in great masses as it is used at Aston. The two lines of angles at the front of the diamond beds give grand masses of white, and in the summer months, when the beds are diamond shapes of dazzling scarlet or golden yellow, the effect is surprising. Each corner of this garden gives a huge mass of Rhododendrons with a background of Cedrus deodara. Then there are also huge turfy angles formed between the arms of the cross, as shown in the design of the flower garden. As I have already stated, the border slopes toward these as toward the paths. This border is planted with

huge masses of blue Forget-me-not, Silene pendula, Tulips, dwarf Roses, among which are Tulips also, and other showy agencies. About the turf are specimen trees, ornamental shrubs, &c., and small flower borders filled at the time of my visit with spring-blooming plants.

That Mr. Quilter marches with the times, is seen in he fact that he has what he terms a "reserve garden," which is not only a place for the reception of the spring plants during the summer months, but also a trial ground, in which is bedded out a small quantity of any new bedding plant that challenges attention. If they succeed here they are used hereafter, if they fail they are condemned as useless. There is also an extensive service of glass, for the propagation of plants—a large nursery, in fact, and it is very interesting to go through the houses and pits during the month of April, and note the quantities of certain leading bedding plants that are being grown on for use in the summer. Such things as Echeveria metallica, for instance, are largely grown, and I saw here, growing in pots, six of the finest, healthiest, and best developed specimens of this plant I have ever met with.

And so I leave Mr. Quilter and his wonderful garden. My enthusiasm as a practical horticulturist was increased tenfold as I looked on the triumphs of the art as seen here; but this gave place to another feeling—that of profound gratitude, as I saw how flowers and their surroundings can be made a mighty lever in the way of social and moral elevation; and I left this place prouder than ever of our pursuit from perceiving the deeper significance of great popular displays of this character. —Via.

FOSTER'S PATENT BOILER.

Mr. T. Taylor, of Lancashire, must be well known if the postman is sure to deliver a letter to his address. I feel I should like to know him (he writes so good-naturedly), and promise him a welcome if he will pay me a visit. He is quite right in one thing—I am a bit of an enthusiast. If an idea strikes me I hammer at it. If it appears a good idea it seems so natural to communicate it to others, that the scribbling fit takes me at once. Having built nineteen houses, some of them amongst the largest in the trade, everything connected with their construction and heating has interested me. If I have suffered in any way from bad construction, badly manufactured glass, adulterated paint, imperfect boilers, or anything of the kind, I have at once written to "our Journal" on the subject. Indeed, I believe no one has been more interested in the subject of horticultural buildings than myself, though I never received a sixpence for advice, or discount on orders entrusted to me. I think I shall turn over a new leaf, and when Mr. Foster makes a fortune by his new boiler, shall send in my claim.

As to Mr. Taylor's remarks, let me say first I always take, if possible, a full hour for dinner, and it took exactly that time to heat the water. I believe a mere "hatful" of fire was what I wrote, but I did not suppose it would be taken literally, using the term for a small quantity. Now, as I find it necessary to be very particular, let me tell Mr. Taylor that having a thick head my hat is rather large, and my man thinks there was at least three hatsful of cobbles on the fire, and that if I had employed the hat as a measure, accuracy would have been gained at no great pecuniary sacrifice. Having, I hope, satisfied my friendly critic on the above points, let me remind him that every one's geese are swans; and though to Mr. Foster alone belongs the credit of rearing the bird, I have taken great interest in the process, and feel for it almost a paternal affection.

I have sent you photographs of the boiler; and if you think it worth while to illustrate this article with a woodcut, I think any of your readers capable of understanding the subject will see at once that to compare a common saddle boiler with it is absurd. Of the many persons who have seen it at work, not one has, in my hearing, taken exception to anything that has been said in its favour. Mr. Veitch, of Chelsea, has ordered one; and I have persuaded Mr. Foster to agree that if it will not heat 2000 feet of 4-inch pipes he will take it back. I am bound to say it is rather against his own judgment he has given this guarantee, but I was very anxious its full powers should be tested. If a boiler costing less than £20, and so easily fixed, should be found capable of heating the above quantity of piping, nothing more will be required to show its value; but if not, I shall still say of it that having, I think it is eight, different boilers at work, there is not one of them but burns quite double the fuel, according to its work, that the new one does, and any one who doubts it shall have the opportunity of testing the same with his own hat for a measure. In case it should be found that a boiler of this construction 3 feet 9 inches in length will not heat satisfactorily 2000 feet of piping, it will only prove that a larger size is necessary, not that the principle is wrong.

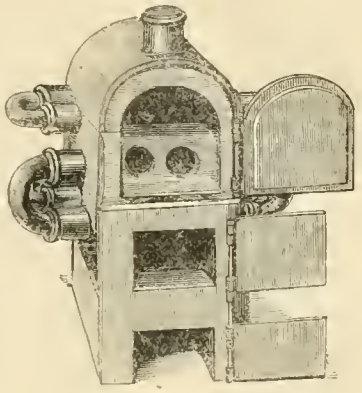

Fig. 1.

Fig. 1 represents the front of the boiler; the lowest door being the ash-pit door, the middle one the fireplace, and the highest door that for cleaning out the soot. *Fig.* 2 is a side

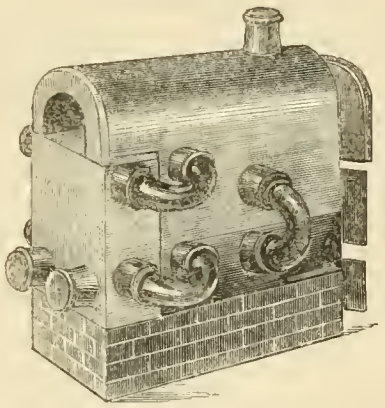

Fig. 2.

view, showing the back against which the flame strikes; after doing so it returns through the two holes shown in *fig.* 1, and then passes back under the arch of the boiler into the flue or

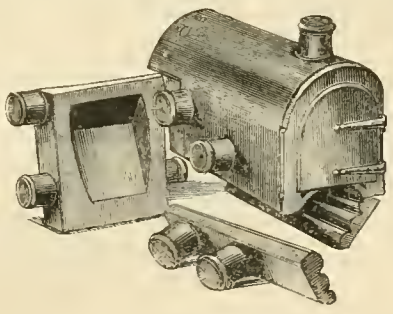

Fig. 3.

chimney. The flow pipe is seen at the top; the two return pipes at the back, and at the side three of the six bent connections uniting the different sections of the boiler. In *fig.* 3 are seen the four sections of which the boiler is composed.—J. R. Pearson.

ORCHARD-HOUSE FAILURES.

I was rather surprised to see by Mr. Pearson's letter of last week that he anticipates nearly a total failure with his orchard

houses, and, moreover, that the failure is universal round him. As there is a like failure out-doors in many places, the loss must be severely felt.

However, if the failure of this season should induce the general heating of orchard houses, it will certainly be a salutary caution. With respect to the advantages of heat, I have a small orchard house here, 25 feet square, containing about forty trees, all planted out, the majority Peaches and Nectarines, with a few Apricots; twenty in the centre bed, the rest round the border and on the end wall, one end of the house being formed by a dead wall. The trees all flowered well, and although we scarcely had a glimmer of sunshine, by the application of gentle fire heat they set well. They have since had several thinnings, and are now, with the exception of six or seven of the trees which I turned out this last season, all well covered with fruit, and are now all in splendid health. On the other hand, there is need to be careful, and not to give too much heat, as that would likely also cause failure. I consider that the most efficient aid in the orchard house is the syringe thoroughly well used, although in unheated orchard houses such a season as we have had would almost prohibit its use.

One remark in conclusion. I think that those who are only in possession of one orchard house may well take this consolation, that when such men as Mr. Pearson fail, failure is unavoidable, and the only thing to be done is to adopt his advice, and put pipes in their houses, and there will be no fear for the future.—J. H. Davis.

REMINISCENCES OF THE ISLE OF WIGHT.

Much has been said and written about the Isle of Wight, its different features, its splendid views, its variety of scenery both by land and water, and its agreeable temperature, owing to the heat of summer and cold of winter being moderated by the sea air. To a great extent this is one reason why the Isle of Wight has become such a favourite resort for the last quarter of a century, during which period the increased facilities for locomotion both by land and sea have been such an advantage to many thousands of the middle class, besides tradesmen in the large towns, and all the artisan class. The Isle of Wight is no less varied and interesting geologically than it is superficially to the less scientific traveller. In a geological sense it seems like a continent crumpled up into a few square miles, and then dropped into the sea close to the shores of England. But my reminiscences must be confined to it as "the garden island," as its natives are so fond of terming it. Let me note one of their words which I have overheard when in conversation amongst themselves—namely, the word "overers," applied to persons who are not natives of the island, they have come over the water. Formerly "overers" were looked upon as persons whom they would charge extra for everything. Some years ago, when sinking a well on the east side of Ryde, the first few yards were of a strong brick earth, then about 2 yards good yellow gravel, the next 25 feet a clean blue clay as fine as if it had been strained through a sieve. At about 22 feet from the surface, and 12 feet into the blue clay, we came upon the trunk of a tree lying horizontally in the clay; when taken up it seemed like a lump of coal, but from exposure to the air it crumbled away. I still have a small portion of it. It was only in the small gravelly portion we found any water; the clay merely acting as a reservoir.

Passing to the south of the island and entering Bonchurch parish you reach East Dene, the marine residence of J. S. Henry, Esq., M.P. The mansion nestles close at the foot of a steep bank, having a few acres in front and about it of comparatively level ground, but at the same time falling away a good deal seaward. In front and round the house are some large trees, principally Elms. At some distance off, overlooking the sea, are the gardens, in which are a number of vineries, pineries, and other structures, and there is a large conservatory by the house. All are in first-rate order. Then come both the old and new churches of Bonchurch, occupying very romantic positions, and well sheltered among trees; while close by is the marine residence of Sir J. Pringle. The entrance from the high road is quite a curiosity. It seems while this portion of the hill had been slipping away to the sea, a huge piece of rock, it may be 200 yards long and 20 or 30 yards wide at its base, and from 30 to 60 feet high, took its lodgment here. These measurements, however, are by guess, but they will give some idea of this rock. Its sides are very steep, and over all are growing shrubs, trees, or grass. The house is not more than 100 yards from the high road. The entrance is by an archway cut through this rock; and the house, a large mansion, is only about 25 yards from the bottom of the rock. Once inside, it will be perceived that a liberal expenditure has been incurred to render this a first-class marine residence, as there are ranges of forcing-houses, and attached to the house a large and lofty conservatory. At a few hundred yards' distance, on the opposite side of the main road, Dr. Leeson in his retirement, made and cultivated several singular little bits of gardens on the shelves of the rocks, trained Pear trees against the rocks, had greenhouses against the rocks, and ferneries running into their clefts.

At St. Lawrence, about a mile west of Ventnor, in one portion of the grounds, an attempt has been made to combine the useful with the ornamental. Along the face of a steep hill are cut terraces from 2 to 3 yards wide, the front of each being walled from 3 to 5 feet high. Against the walls were Vines. The half of the level terrace next to the top of the walls was laid out in flower border, the other half being walks. A walk passed in at the bottom, having a flower border beyond it; then came a piece of grass with trees, and at the top of all these terraces ran a row of upright irons with chains suspended between, having Roses growing over them so as to form festoons. A little further to the westward are some very large Fig trees, yielding every year large crops of fruit.—G. Dawson.

NOTES AND GLEANINGS.

The new Southwark Park was opened on the 19th ult., by Sir John Thwaites, the Chairman of the Metropolitan Board of Works. It consists of sixty-three acres of ground, formerly market gardens, situated near the Spa Road Station, about a mile from London Bridge—a densely populated neighbourhood, to which it will, doubtless, prove of great advantage as lungs, and as a place of recreation. It was laid out by Mr. A. McKenzie, of Alexandra Park, and has cost upwards of £95,000. A large space is devoted to a cricket ground, and other spaces to shrubberies and a flower garden.

—— We have just returned from a visit to the nurseries of Mr. William Paul, at Waltham Cross, and by the time these pages are in the hands of our readers, the Roses in that nursery will be breaking out into a blaze of beauty. We are afraid to say how many thousands there are in the nurseries altogether, but fifteen thousand in one "piece" is a sight worth seeing. Mr. Paul's new seedling, Princess Christian, is one of the grandest Roses in cultivation—a Titan in growth, with foliage large and glossy, and a bold flower, having the unsurpassed form of the "old Cabbage," and a colour reminding one of the under-cooked flesh of a grand salmon—that is the Rose Princess Christian.

—— The following are the results of the recent examinations of gardeners, by the examiners appointed by the Society of Arts:—In Floriculture the first prizes of £5 each, offered by the Society of Arts and the Royal Horticultural Society, were awarded to Michael Middleton, aged 22, of Richmond; and the second prizes of £3 each, to R. I. Lynch, aged 19, also of Richmond. In Fruit and Vegetable culture, the first prizes of £5 each, offered by the same Societies, were taken by Michael Middleton, and the two second prizes of £3 each, by Alfred Bradley, aged 26, of Deptford. The certificates granted were as follow:—

	Floriculture.	Fruit and Vegetable culture.
A. Bradley, Deptford (26)	1	1
B. Cargill, Liverpool (27)	3	—
C. Fryer, Lambeth (28)	3	—
F. Hardisty, Edinburgh (26)	2	2
J. C. Higgs, Southampton (28)	2	—
C. Lawton, Hull (25)	1	2
R. I. Lynch, Richmond (19)	1	—
J. McPherson, Southampton (23)	—	3
M. Middleton, Richmond (22)	1	1
W. Nettleton, Huddersfield (31)	2	—
W. Parkinson, Liverpool (23)	3	3
W. Ritchie, Edinburgh (22)	—	2
J. Smith, Richmond 27)	1	1
T. Smith, Hull (18)	8	3

—— The following prizes are offered for competition at the meeting of the Fruit and Floral Committees, to be held on Tuesday, July 6th—viz., 1, Twenty-four Carnations, cut blooms, distinct (Nurserymen), £1 5*s*., £1, and 15*s*. 2, Twelve Carnations,

cut blooms, distinct (Amateurs), 15*s*., 10*s*., and 7*s*. 3, Six Carnations, cut blooms, distinct (Amateurs), 10*s*., 7*s*., and 5*s*. 4, Twenty-four Picotees, cut blooms, distinct (Nurserymen), £1 5*s*., £1, and 15*s*. 5, Twelve Picotees, cut blooms, distinct (Amateurs), 15*s*., 10*s*., 7*s*. 6, Six Picotees, cut blooms, distinct (Amateurs), 10*s*., 7*s*., and 5*s*. 7, Thirty-six Carnations, Picotees, and Cloves, mixed, cut blooms (Nurserymen), £1 10*s*. and £1. 8, Twelve Carnations, Picotees, and Cloves, mixed, cut blooms (Amateurs), 15*s*., and 10*s*.

—— The floral decorations at Buckingham Palace in honour of the visit of the Viceroy of Egypt, were supplied by Mr. Wimsett, of the Ashburnham Park Nursery, Chelsea.

WORK FOR THE WEEK.

KITCHEN GARDEN.

The frequent showers we have had of late have been most favourable for the operations of this department. Every yard of ground that can be spared should be planted with winter vegetables. Stir the surface of the ground amongst all growing crops where practicable; doing so will enable the rain to percolate through it more equally, and will check evaporation. If not already done, a good breadth of *Brussels Sprouts* should be planted in rich deep soil, for if not planted at once the crop will be poor, and it is very desirable to secure a good supply of this most useful winter vegetable. *Endive*, those who desire a good and constant supply of autumn and winter Endive must make a full sowing at once. Endive is generally sown too thickly. Another sowing may be made about the middle of the month, after which the plants will not attain their full size. As soon as they are a few inches high mow the tops of the leaves off with a scythe, cutting about one-third of them away.

FRUIT GARDEN.

Those who fully understand the importance of thoroughly ripening the wood of all trees on walls and espaliers will, of course, pay attention to thorough thinning and early training. We cannot expect Peach trees to ripen their wood perfectly when the young shoots are dangling from the wall until August. Pear trees at this period should also have as much attention as Peaches. The breastwood must be kept short, and in doing this remove it from the upper half of the tree first. Proceed with the fastening-in of the young wood of wall trees, and see that they are perfectly free from insects. Gross shoots that were stopped early in the season should be divested of all laterals except one, or, if they can be spared, removed altogether. Look to preparing Strawberry runners for forcing next season. When Strawberry plants have ceased to bear for the season, and have borne on the same ground for three successive years, they ought to be trenched down, and the succession kept up by making fresh plantations of those that have been forced, taking care that the soil is trenched and well manured at least 2 feet in depth. Currants growing against walls or other fences ought now to be matted over, to protect them for use in autumn and winter. See that the shoots of young grafts are nailed or tied up as they advance, to prevent their being broken by the wind.

FLOWER GARDEN.

Late-sown annuals should be thinned so soon as they are well above ground, for if left to grow too thickly they spoil one another, and never make half the display that plants do which are allowed plenty of space, and which are grown strongly from the first. Attend to staking such of the herbaceous plants as require it before they are blown about and injured, and do not huddle the stems together, as is too frequently done. Early-flowering bulbs, as Tulips, Hyacinths, Turban Ranunculuses, &c., will now or very soon be ready for taking up, and should not be left in the ground after the decay of the foliage, as, if wet weather occurs, they will be making fresh roots, which weaken them for next season. On light, dry soils American plants will be greatly benefited by a good soaking of water after flowering, and the finer sorts should be mulched to assist in keeping the roots moist during the growing season. Attend to the propagation of the better sorts of Pentstemons, which are exceedingly useful plants; also see to having a good stock of border Picotees and Carnations, which are invaluable for cutting, and although now discarded from the parterre, should not be overlooked. Cuttings of these put in before they become too hard, root as freely as Pinks. Water Dahlias during dry weather. It will be serviceable to mulch the surface of the soil with rotten manure. Trap earwigs and other destructive insects. All newly-bedded-out plants will, during hot weather, require attention in watering. Attend diligently to standard Roses; constant disbudding is necessary at this period, also keeping down suckers. Let every attention be paid to propagating a reserve stock to fill gaps, and let plants already rooted, or the remains of store pots, have kindly cultivation forthwith, in order to be ready for that purpose.

GREENHOUSE AND CONSERVATORY.

Now that the conservatory is relieved of all superfluous stock, nothing remains but to carry out a cleanly system of cultivation, and to introduce fine specimens from other houses. This house should now be gay with Achimenes, Clerodendrons, Allamandas, Gardenias, Stephanotis, and other showy plants from the stove, for without the assistance of these it is hardly possible to produce a first-rate display at this season. If the house can be kept rather close, many of our more attractive stove plants will be more at home there while in bloom than they would be in the stove itself; and the length of time they retain their beauty under these circumstances renders it very desirable to grow them largely for this purpose. To do them justice, however, the house should be cleared of Cape Heaths, and plants that are soon injured by a confined atmosphere, for few stove plants will succeed in a temperature that is regulated for Ericas and similar plants. If the present occupants of the beds and the twiners, however, are such as require a free circulation of air, the house must not be kept so close as to injure them; but where Passifloras, Ipomæas, Mandevilla suaveolens, Tecomas, Begonias, &c., are grown for covering the roof, and Orange trees and other subjects which enjoy a fair amount of warmth and moisture while making their wood occupy the beds, the hardier stove plants will form the most suitable decoration for the next three months. Go over the twiners frequently and regulate the growth before the shoots become entangled, but avoid keeping them tied too closely, for they are never seen to advantage unless they are allowed to hang down in a natural and graceful manner. Sickly specimens must be frequently examined for insects, and means used to destroy their enemies as soon as they are perceived, otherwise they will spread to adjoining plants and be more difficult to eradicate than if taken in time. With respect to mixed greenhouse plants pursue the directions given for the conservatory. Use abundance of water morning and evening with a particularly free circulation of air. Continue to make cuttings of gay-flowering plants for a late autumn display. Camellia stocks may now be grafted, choosing the young wood which has the leaves perfectly developed, and which is of a ripening brown at the base. A slight hotbed affording a bottom heat of 80° from fresh fermenting material, will be found suitable for them, placing a foot of cinder ashes over it to keep down worms. Amaranthus melancholicus ruber makes a fit edging plant under glass, and a good supply of it should be secured for that purpose.

STOVE.

As regards stove plants, a very free use of the syringe with abundance of air night and day should be persisted in, the main business being to produce sturdy plants with short-jointed wood. Liquid manure composed of cow drainage, guano, and soot water should be constantly in use, taking care to employ it in no other way than clear and weak. Give air liberally to Orchids, syringing them freely early in the morning, and shutting-up early in the afternoon. The stock will now be growing very rapidly, and must be afforded sufficient space to allow of perfect development of the foliage, and the formation of compact handsome specimens. A slight shade will be indispensable for tender plants in active growth for a few hours during the forenoons of bright days. Plants that are known to suffer from the direct action of the sun's rays should be placed in a shady part of the house, or kept together at one end where they can be shaded without interfering with plants that require plenty of light.—W. Keane.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

The 25th and 26th ult. have been as yet the only fine hay days in this quarter. The latter day, Saturday, was hot and parching enough, after so much dull moist weather, to try many crops recently planted, as Cauliflowers, Lettuces, Brussels Sprouts, Broccoli, &c., and a little water was given to them at the roots to prevent them feeling the effects of a too rapid evaporation from their foliage. One great essential to rapid

success in all departments of gardening is never to allow a plant or a cutting to flag. We have no faith in cuttings or Cabbage plants which have flagged if they can be avoided. We have seen Cabbage and Cauliflower plants carried in bundles with the roots exposed, and left lying about before planting, as if the more withered the foliage, and the more parched-up and destroyed every fibre of roots, the better might the plants be expected to thrive. Just so with *cuttings*, they often are so carried and tumbled about that they are half-dead before they are made and planted. There is one rule which, though not appertaining to this department, is universally applicable in growing cuttings of all kinds, and that is, whenever a cutting is taken from its parent plant, put it as soon as possible into its new position, and then prevent the evaporation of its juices too freely by shade or a close moist atmosphere. A second good rule is, when cuttings are brought from a distance, and they become a little withered in the journey, never to place them in water to revive them. This is often done by beginners and the inexperienced, and though it often seems to freshen up the cuttings, it generally so fills the stem with watery juice that there is a likelihood of rotting or damping-off afterwards. The far better plan is to lay the cuttings down thinly in a shady close place, and sprinkle them all over with water, making thus the floor on which they rest damp. The foliage will thus recover its healthy appearance, whilst little extra moisture will be absorbed by the base end of the cutting. Cut flowers may often be preserved a long time in fresh water if a small slice be cut off the base of the shoot every day. A fresh basis for absorbing liquid is thus given. Without such care the base of the shoot soon decomposes, and this is what we wish to avoid in the case of a cutting.

Exactly the same principle, though in a modified degree, should be acted on in *planting out* with the dibber Cabbage and Broccoli plants. If the plants are raised at home, it is well to puddle the roots as taken up, to prevent the fine fibres becoming parched up in the mere carrying to the ground. When brought from such a distance that the leaves are likely to be flagged on arrival, it is well to puddle the roots before starting them on the journey, and if not so treated, to do so when they arrive; but in either case, never allow them to stand any time in water, but rather lay the plants down thinly, and damp them all over, which will soon swell the foliage and the stems. We have often been pained at seeing thousands of bundles of young Cabbages and Greens so marketed and exposed in the journey home, that every fibre of the roots was parched up, and though the plants ultimately flourished, they did so from the inherent force of vitality enabling them in self defence to put out fresh roots from the main descending axis of growth. If the roots of such bundles had been wrapped in damp litter, or even protected with a Cabbage or Rhubarb leaf tied firmly round them, there would have been a considerable gain of time as to fitness for use. We have seen hundreds of bundles of such plants in markets, where from lying on each other the foliage did something to protect itself, but with the root ends all exposed as if they could not be dried enough.

Peas and Beans.—Hoed all the ground about them to keep moisture in, but a few days of such weather will render it necessary to give them water at the roots where bearing heavily. If let alone, this promises to be a good season for Peas. Our late-sown ones have not been touched since we put a few poisoned pellets beneath the open wire netting, but we are almost beaten by the sparrows. They made many a breakfast on the buds of the earliest, and now frequently save us all trouble in gathering and shelling the pods.

Celery.—The great point now, until earthing-up time, is never to let the plants become dry. Every time they are allowed to feel the want of moisture is an inducement to the plants to throw up their flower stems, when, however blanched, they are fit for nothing but soups, and scarcely for that. In the parching summer of last year we saved ours from bolting by a dense shading for fully a month. If we should have a few more such bright days, we shall stick a few branches by the sides of our beds, to prevent such a free evaporation from the foliage and soil.

Cucumbers.—Banked up the frames to keep a regular temperature, and ere long will remove plants from a pit, and plant others in fresh soil, as they are showing the effects of heavy cropping. We met the other day with one of the most successful Cucumber-growers, who has a very neat span-roofed house for the purpose, and for two or three years the disease has nearly mastered him, although he has procured fresh seed from great distances. No place, be it pit or frame, is exempt from the pest; though at a short distance in another place, no sign of the disease has appeared.

Pea Gathering.—Even this simple matter requires system. Many a row only yields half the produce it would have done, because the gatherer in plucking the pod nearly pulls up the Pea plant. The very precise may nip off the pod by applying small scissors to the stalk of the Pea, but the simplest plan is to use a small sharp-pointed knife in severing the stalks, and no strain is thus given to the Pea plant.

Dwarf Kidney Beans.—A good supply of these is useful now, before they can be obtained in the open ground. In heated houses it is rather dangerous to have them, except in a pit appropriated entirely to them, as in hot sunny weather they are so subject to red spider and thrips. They suffer little from such pests when merely covered with glass—such as old sashes. We have had a plentiful supply, grown in pots in a little heat, and then turned out pots and all. A second supply in an earth pit just showing bloom was grown, four or five in a 6-inch pot, and then turned out into the ground. The dwarf kinds are best for this purpose, and even they on the whole do best when stopped at the first or second joint above the seed leaves. We lately met with one not so generally known as it ought to be, grown in-doors and out of doors, almost to the exclusion of every other kind, by Mr. Beales, at Wharton Wood Hall, and named Sir Joseph Paxton's Kidney Bean. The Bean itself is small, about the size of the Newington Wonder, but it produces a fair-sized pod in great abundance, though even in a hothouse the plant continues very dwarf and needs no stopping. The latter fact is of importance for forcing and early work, as the stopping delays the blooming. The slightest glance showed us these distinctive features, which we hope to turn to future advantage. We do not know how this variety came to be named after the great gardener, but some of our readers may be pleased to learn, that the same substantial wooden bedstead on which Sir Joseph slept when attending the furnaces at Wood Hall, is still doing good service; and let us hope, as there is much even in little circumstances, may do something to foster the genius of other youths who will be as great in gardening, and as worthy in true manliness of character as Sir Joseph Paxton.

We need not repeat the importance of planting winter vegetables in every available space. We only wish we had more space at liberty. When that cannot be done, the next best plan for securing a good return in winter, is to plant out in rich rough soil, at from 4 to 6 inches apart, and raise and plant with balls. On the whole we find this plan answers better than planting at once between rows of Potatoes, Peas, &c., where the plants are likely to be drawn up by shade.

If this hot weather continue, *Cauliflowers* will need abundance of water. This season, amongst our earliest, which had the help of hand-lights in winter, we had six or seven of what might be called flowery heads, more open and green than usual, not fit to send to table, though, as far as we could judge, the plants seemed the same, the rest yielding noble close white heads. What can be the reason for this departure from the normal state? We have chiefly depended on the London Market Cauliflower, for though a little long in the leaves, it yields fine returns; but there is a much more compact kind, as respects foliage, grown on the east side of Hertfordshire, by Mr. Hill, of The Poles, Mr. Beales, of Wood Hall, and Mr. Cox, of Kimpton Hoo, all, we believe, with different names as Hill's Cauliflower, Hertfordshire Cauliflower, Cox's Cauliflower, &c., and all to a stranger seeming very much alike, but marked chiefly by the broad-spreading leaves, the comparative dwarfness of the plants, and the good size, compactness, and whiteness of the head. We have found that even the London Market Cauliflower assumes the best of these properties when thinly planted, and that the superior kind or kinds become long-leaved when thickly planted. Amateurs, and gardeners too, in choosing the best varieties, should give these fine Cauliflowers a fair trial. When from home for a few hours lately, we noticed a fine white Broccoli of Mr. Cox's, just heading when most others were gone; and we find that Mr. Francis, of Hertford, has a cream or sulphur-coloured one, that rarely comes in until June—a matter of importance where early Cauliflower cannot be easily had. For the table, of course, the white looks best; but we have found cream and purple-coloured often richer and sweeter in flavour.

FRUIT DEPARTMENT.

So late is the season, that with us Strawberries out of doors, with the exception of a few of the Black Prince, are only beginning to colour. Fortunately, we shall have a supply for some

time longer under glass, and Peaches are now coming in from Peach houses to make up for the deficiency of Strawberries out of doors. As already stated, our out-door Strawberries will not be a good crop, owing to the parching effects of last season on the crops, and watering being out of the question. Water is so very essential in a garden, that the means of supply should be carefully considered in the formation of all new gardens. What comparison can there be as respects management and results, where in a dry season every pond must be brought into requisition, and horse and cart employed as long as any water lasts, and the case of a garden where for syringing walls, watering borders, and flooding quarters, nothing more is required than a flexible pipe screwed on the end of a tap with a man or boy at the end of the pipe to direct it aright?

Peaches swelling and ripening had a fair supply of water; later houses had the shoots thinned, and in a few cases, but not many, the fruit well thinned, as in most cases it is thin enough in late unheated houses, and we shall have few on the open wall, though they showed plenty of blossom. We stated our apprehensions on pruning the trees in spring. The buds were parched in the dry weather from want of water, and the autumn growth made the matter worse, and there was no sun to open and foster the fertilising pollen, and hundreds of pistil points we closely examined never had the means of secreting the moisture on their summits, so as to catch and transmit any little pollen dust that might have reached them. Except where heat was applied, and growth was perfected more early, we shall be scarce of stone fruit, except Cherries and Plums. Even Apples which set thickly, have dropped numbers of young fruit, and numbers of young bush trees have a brownish hue instead of the rich green with which they used to cheer us. We expect that some Pears and Apples will drop, and more especially when for three following seasons the trees have been heavily laden; but more have dropped this season than usual, which we attribute chiefly to the roasting which the shoots and buds had last season.

We went over part of our fruit trees, shortening, pinching, and thinning the young wood, so as to admit light and air nearer home. We would have been at this work earlier if we could have found time. Whatever else should be neglected no time should be lost in stopping or removing over-luxuriant shoots; they not only rob other moderate growers of their proper strength, but are useless themselves for any purpose, as their extra luxuriance will prevent their due ripening, so as to be fruitful. Fresh-planted trees have had a little water at the roots. The natural moisture and the coldness of the soil have rendered the little quite sufficient for the purpose. As the ground gets warmer more will be necessary.

ORNAMENTAL DEPARTMENT.

Merely as a proof of the coldness of the soil, our Scarlet Pelargoniums, &c., out of doors, have done but little more than hold their own, the flowers are still rather few, the plants anything but masses of colour, whilst some Calceolaria beds and groups are really thickly studded with bloom. So far as they are concerned, provided we could keep the ground as moist and cool as it is now, and give them plenty of bright sun, we should have no reason to find fault with their not thriving and blooming, as then we should be furnishing them with their normal conditions of natural growth on the lofty hillsides of Peru and Chili. Most of our rather tender plants that we cultivate under artificial circumstances, like the water given to approximate in temperature to that of the atmosphere of the house, but, as a general rule, the whole tribe of Calceolarias prefer cool water to that which is warmed. The great essentials to their free growth and free blooming are a bright sun and a cool damp soil. We cannot easily secure the latter conditions in a hot summer, as the soil will partake of the warmth of the atmosphere, but still we can do much by surface-stirring and surface-mulching. If we have a few days of this fine hay weather, we shall mulch our Calceolarias with rotten dung to keep the heat and dryness from their roots.

Our few first-planted Perillas have been removed as the worse for the cold weather, and our bulk is planted out, consisting of good strong plants, which now we expect will go on well. Some plantations we have seen of young Coleus turned out, looked very miserable, and will only recover from the check from cold if we have sufficient heat to warm the ground and cause them to break afresh. We are now exposing ours in pots, night and day, and having turned the ground several times, we shall most likely plant out in the ensuing week. As the plants are of a good size, they will nearly fill the space intended at once. Of course, they have taken up valuable room under glass, but, except in warm sheltered places, it is of little use turning out small plants, say in the end of May, or the beginning of June. One of our best gardeners, unwilling not to finish the flower garden at once, turned out his Coleuses in the beginning of June, and scarcely a single plant will break afresh, and he has been forced to propagate and forward a young stock. Under general circumstances much north of London, we have no faith in small plants and early planting in cold soil. Our hopes for a fine, massive, rich-coloured bed, must mainly depend on warm rich soil, good-sized plants, and water well warmed with the sun.

Directing attention to previous numbers for general work, we would say a few words on sending bedding plants, &c., great distances at this period—that is, the packing of a great number in little bulk. Of course, when nurserymen send plants, each standing upright in a wide, shallow hamper, there can be no danger; but when gardeners and amateurs assist each other, as they often do at this time, and send the plants laid down in a box or hamper, the plants often suffer greatly before they reach their journey's end, chiefly from shaking and heating; the first from loose, and the second from too-close packing, and using grass, hay, and other unsuitable materials. We have opened a middle-sized hamper, and could scarcely hold our hand in the centre of it, and, of course, the plants were so heated, as for the most part to be useless. A good many dozen of little plants, even showing bloom, may be sent safely in a middle-sized hamper with a little attention to the packing. We have known some hampers which were not delivered under ten days, from having to traverse several lines of railway, and yet the plants did good service. The plan we have found the best, when numbers are to go in little space in a hamper, is, after the ball has been moistened and allowed to part with extra moisture, to wrap it in a thin leaf, as horse-radish, or a wetted rhubarb leaf, and pack all the balls round the sides of the basket, with the heads to the inside. Spray of dried larch, spruce, or other wood, was placed between the layers of the heads, so as to make the heap not only firm throughout, but to allow air to pass freely among the tops of the plants from top to bottom of the basket. If anything else is used, so as to be a little softer next the foliage, as moss, &c., it should be as dry as possible, damp moss or damp grass being very objectionable. If the earth about the roots is just moist, it is better than if it were at all soaking wet. Everything damp is to be avoided. Dry larch and spruce spray we like the best, but the small chippings of spray from Pea sticks, &c., answer very well. A large hamper thus packed will give no signs of heating. If a box is used, bore holes in the top and bottom.—R. F.

COVENT GARDEN MARKET.—June 30.

The demand scarcely comes up to that of last week, but a fair average amount of business is being done, and large quantities of goods have been despatched to the northern markets. Pine Apples are considerably in excess of the demand, and 20,000 West Indian Pines are reported in the river. Large quantities of Potatoes from the Continent and Channel Islands continue to arrive, the price varying from 8s. to 20s. per cwt.

TRADE CATALOGUE RECEIVED.

T. L. Mayos, Lugwardine, Hereford.—*Catalogue of New and Choice Plants and Bulbs.*

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely to The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week

Hawking Plants in Pots (*T. R.*).—If a person hawking plants in pots travels with them from town to town, or calls at people's houses, he requires a hawker's license.

Viola cornuta (*G. H. W.*).—We cannot give an opinion without seeing both kinds of leaves; nor can we name Beans which we have never seen.

Vines Syringing and Stopping (*G. H.*).—As the Vines are now in their stoning stage, you ought to keep the floors, walls, and flues moist by sprinkling them with water twice a-day at least, and three or four times would not be too often on very hot days, up to the time of the Grapes changing colour, when sprinkling should be discontinued. We fear you have in the "many bunches covered with something like dust" the mildew, but that we could not determine without a specimen. The remedy for that is to dust with flowers of sulphur. The shoots ought to be kept stopped to within a few leaves of the bunch, not allowing them to ramble until the Grapes have swelled off. Enough leaves should be left to shield the bunches from too powerful sun, and to elaborate the sap. It is well to have a moderate amount of foliage, but do not allow it to ramble and then reduce it wholesale. We cannot name plants from leaves only; flowers are necessary.

Orchard-house Constructing (*K. H. B.*).—The situation, we presume, is open, and has the sun's rays all the day, without obstruction from buildings or trees. The sides and ends will answer well, formed of boards, tongued and grooved, and put together very closely. The uppermost but one may be hinged for ventilation. It should be 11 inches wide, and made to open the entire length. A span roof would be best, and you could have the boards hinged at both sides, and that would give sufficient ventilation. The boards need only be dressed on the side which is towards the interior of the house. The outside being rough, may be coated with boiling coal tar, but the smooth surface may be painted with white lead. If the house be a lean-to, there should be openings for ventilation at back, immediately under the wall plate, as well as the hinged board in front. We presume you do not intend to still use the house as a poultry yard.

Dracæna Leaves Browned (*In-a-Fix*).—By keeping them shaded you will secure a more equable temperature, and the leaves will not spot or become browned at the tips; but in the shade they will be of bad colour. We do not syringe ours at all, but give them a light and airy position and abundance of room. We admit a little air early so as to dissipate any moisture condensed on the leaves during the night, and have the foliage dry before the sun shines powerfully upon them. The atmosphere should be kept moist by frequently sprinkling the floor, walls, &c. To have the plants in good colour for winter they should at once have light, as those now formed green will to a great extent continue so. The more light such plants have, the better coloured they will be; but if shaded they will grow more, and not be so liable to become brown, or go off at the tips of the leaves.

Coldstream Early Potatoes (*A Simple Scot*).—You are quite correct in stating that this very closely resembles Smith's Early. It is rather superior, but should be sold for about the same price.

Horseradish Leaf (*Mrs. White*).—The white spots are a parasitic fungi of a genus occurring on the dead and decaying leaves of the Cochlearias

Guano Water Producing Green Fly (*John B.*).—It will not induce, but rather act as a preventive of green fly.

Pelargoniums after Flowering (*Idem*).—Place them out of doors in a slightly-shaded position, supplying them with water as required, but not so much so as when growing, and yet not allowing the foliage to flag. Prune in August, and in September place them in a cold frame, setting the pots on coal ashes, and give no more water than enough to keep the soil moist; protect from heavy rains, but admit air by tilting the lights. When they have shoots an inch long, shake the plants out of the pots, and repot in others no larger than sufficient to hold the roots properly; return the plants to the frame, keeping it rather close and shaded for a few days, then expose them fully to light and air, protecting, however, from heavy rains. At the end of September or the beginning of October remove them to a shelf in the greenhouse, where they can have abundance of light and air.

Roses after Forcing (*Idem*).—Plunge the pots in coal ashes quite to the rim, and give the plants plenty of room. The situation should be open and warm. Supply them well with water, in September repot, and at the end of October remove them to a cold frame, plunging the pots as before, and admitting air on all favourable occasions, but protecting from heavy rains and severe frosts. During the latter, a covering of mats in addition to the lights will be desirable. Prune in November or December. The plants may be taken from the frame as required, and placed in the greenhouse or forcing pit.

Piozons' Dung (*A Subscriber*).—It is not so powerful a manure as guano, but is, nevertheless, one of the best manures, and may be safely used to all kinds of flowers, fruit trees, and vegetables. It should be thoroughly mixed with an equal quantity of dry soil, and stored in a shed where it will be kept dry. By being laid thinly, turned over frequently, it is kept from heating, as when it heats, as it will do if laid thickly, its fertilising constituent, ammonia, is to a great extent lost. About 1 inch in thickness is a good dressing, and may be applied now as a top-dressing to the soil near Roses and fruit trees, and again in March, neatly pointing it in with a fork, if that can be done without injury to the roots; if, however, they are near the surface, it will be sufficient to cover the manure with a little soil. For vegetables it should be applied previous to planting and dug into the ground.

Aphides on Rose and Fruit Trees (*Mrs. G.*).—There is, as you say, an unusual abundance of these pests this year, owing, no doubt, to the prevalence of cold north-easterly winds. We do not know of a better mode of destroying them than dipping the shoots on a dry evening in tobacco water, which may be obtained at any tobacco manufactory, or it may be made by pouring four gallons of boiling water on 1 lb. of the strongest tobacco, covering up, and then the tobacco should be strained and squeezed so as to express the juice. If the shoots cannot be dipped in the tobacco water, it may be applied with a fine-rosed watering-pot or syringe. There is another effectual mode of clearing off the aphides—namely, to syringe the bushes on a calm evening, and whilst wet dust them with tobacco powder, giving the bushes a good syringing the following evening. The bushes may be washed in autumn or winter before the buds begin to grow, with a composition of 4 ozs. of soft soap to a gallon of tobacco water, made from 4 ozs. of tobacco in a gallon of water; adding enough sulphur vivum, soot, and a lump of lime, unslaked, about twice the size of a hen's egg to bring the mixture to the consistency of thin paint, applying it with a brush to all the parts of the shoots and stems after pruning, rubbing it well into the angles and crevices of the bark and stem, and taking care not to dislodge the buds.

Select Roses (*Henry Bedwell, Lancashire*).—"Cloth of Gold and Maréchal Niel are so precarious, that I do not care to recommend them, but they are the finest of the yellow Roses, and would do well under glass. To your collection of seven Roses add these. They are free-blooming, and successful Roses here, and, in my judgment, they are the *elite*. *Yellow:* Gloire de Dijon, Triomphe de Rennes, Céline Forestier, and Solfaterre. The last requires a S. or S.E. wall. For free and continuous blooming, no yellow Rose has a chance with it, good and excellent as are the two first named. *Rose colour or Pink:* Baronne Prevost, William Griffiths, Gloire de Vitry, Comtesse de Chabrillant, John Hopper, Charles Rouillard, Baron Gonella, Comte de Nanteuil, Princess Mary of Cambridge, Paul Verdier, Monsieur Noman. *Blush:* Abel Grand, Marguerite de St. Amand, La France, Duchesse d'Orleans, La Sœur des Anges, Madame Knorr, Madame la Baronne de Rothschild, a magnificent Rose. *White:* Baronne de Maynard and Madame Alfred de Rougemont. *Darkest Crimson, or Maroon:* Prince Camille de Rohan, Duc de Cazes, Pierre Notting, Souvenir de Dr. Jamain, Baronne Pelletan de Kinkelin, Empereur de Maroc, Souvenir de W. Wood, Vicomte Vigier. *Crimson, Cherry colour, or Carmine:* Charles Lefebvre, Marie Baumann, Alfred Colomb, Maurice Bernardin, Lord Macaulay, Madame Victor Verdier, Senateur Vaisse, Exposition de Bric, Dr. Andry, Lady Suffield, Marshal Vaillant, Jules Margottin, Madame Boutin, Baronne Adolphe de Rothschild, Madame Clemence Joigneaux, Duchesse de Caylus, Leopold Premier, Madame Julie Daran, and Achille Gonod. It is impossible to speak too highly in every respect of the two new Roses, Marie Baumann, and Mme. la Baronne de Rothschild. I have other new Roses here, but I will not speak of them, though I think some of them very promising, till I can speak confidently. If you wish for more white Roses, I recommend the two Tea Roses, Madame Willermoz and Sombreuil. The latter is as hardy as a Hybrid Perpetual, a strong grower, and continual bloomer. Acidalie is fine, but probably it would not bloom freely in Lancashire.—W. F. Radclyffe."

Purifying Air (*G. H. M.*).—You need be under no apprehension that the air of Forest Hill is not sufficiently pure for Roses. We know where they flourish much nearer London, and close to Manchester, Birmingham, and Sheffield. If it were otherwise, there is no chemical that would purify the air as it entered the Rose-house.

Froth Insect (*R. W.*).—If you remove the froth with a sponge you will find an insect within, which produces the froth. The insect is called by entomologists Tettigonia spumaria, and Aphrophora spumaria by some. It is the larva which is inside the froth, and it should be destroyed, for by its sharp rostrum or beak it extracts the sap of the plants it infests, and voids it as an excrement in the frothy foam.

Raising Vines (*Idem*).—You will not succeed very well in the open air, but by making a frame and forming a hotbed, you may raise them in quantity. The wall might form the back of the frame, and you would only need a front wall and ends, making an excavation so as to allow for fermenting material, which should be at least 4 feet deep, and there should be a height of 2 feet for the plants to grow in. The excavation might be 6 feet wide or more, and any length. Fill it with hot dung in the first week in March, and pot in the eyes or cuttings in 3-inch pots, plunging them in sawdust, but the bottom heat must not exceed 90°. The plants should be potted in 6-inch pots when the smaller pots are full of roots. The cuttings or eyes may be potted in February, and kept rather dry until placed in the hotbed, and in July the pit may be emptied partly or wholly, according as the plants grow, to give them head room, a stick being placed in each pot to train the Vine to. If the Vines require it, they may be potted in 9-inch pots. They should be kept rather close and well watered, but not excessively, so as to encourage a good growth; keep them dry after September, so as to ripen the wood. In the following March they may be planted out where they are to remain, cutting them down to two eyes. Another batch of eyes may then be started. The Vines would not be in a bearing state until the fourth or fifth year. We shall shortly treat of the out-door culture of Grapes, or those against walls, when your queries will be more fully answered. We cannot say whether you can grow Grapes profitably on walls, so much depends on the locality. In quality they are about equal to foreign Grapes, and are worth, when first-class, about 1s. 6d. per lb. We have known them bring

less than 4*d.* per lb., when, as they often are, they were of very inferior quality.

Engine-house Windows (*J. K.*)—We fear there will not be a sufficient command over the temperature to enable you to grow successfully any kind of fruit; but you might try Vines and Figs in pots. Plants would succeed, their foliage being kept clean by frequent spongings. Store plants would be most suitable, but would not the plants obstruct too much light? A few of those most likely to succeed are:—Tillandsia splendens, Puya Altensteini, Ardisia crenulata, Æchmea fulgens, Cereus grandiflorus, C. McDonaldi, Clivia nobilis, Epiphyllum truncatum, E. violaceum grandiflorum, E. Salmoneum, Ficus diversifolia, F. elastica, and Crotons variegatum and pictum.

Polyanthus Seed not Germinating (*Idem*).—The probability is your seed was bad, otherwise your plants would now be strong. They usually appear within a month from the time of sowing.

Pyramidal Gooseberries and Currants (*A Poor Lady*).—Both are bushes, and succeed best grown in that form. You may, however, have them as pyramids by putting in a stake to each plant and heading it down to 1 foot from the ground. The heading-down being done in autumn will secure shoots in spring. One of them must be trained as a leader, erect, and other shoots tied down, rubbing off all above three. These in autumn are to be cut back to 1 foot from the stem, and the leader shortened to that extent. In the spring following the shoots from the leader are to be treated as in the previous year, only any shoots not required may have their points taken out when they have made three leaves, and be kept closely pinched back to one leaf afterwards, shortening them in autumn to within an inch of their base. The side shoots will need to have some of the shoots proceeding from them stopped, as described above, allowing such as are advantageously situated to grow so as to furnish shoots for bearing. They should be trained-in their full length, and so as produce a uniform compact head, and not nearer together than 9 inches, though they may for a time be left 6 inches apart, and afterwards thinned out. The leader will need to be shortened in autumn to 1 foot, the second tier of side shoots cut back to 9 inches, and those from the second growth of the first tier cut back to about 6 inches, leaving them longer or shorter so as to keep their extremities in the same tier, at one distance from the stem all round. The shoots stopped should be cut back to within an inch of their base. The treatment in subsequent years is only a repetition of the above, the object being to stop all shoots not required for extension, or the formation of the head, at the third leaf, keeping closely pinched afterwards to one, and cut them back at the winter pruning to 1 inch from their base. The extremities of the main shoots should, when the bush or pyramid is wide enough, be cut to 3 inches at the winter pruning, and in summer be stopped at the sixth leaf. They may be grown to any height. We have seen 6-feet standards, but we think them quite tall enough at 4 feet, and prefer them as bushes not exceeding 3 feet 6 inches high.

Cutting-back the Laurel, Arbor-Vitæ, and Box (*E J.*).—The best time to cut-in evergreen shrubs, the object not being to make them formal, but to get rid of too great a size or irregularity of growth, is at the beginning of May. It may, however, now be done, it not being necessary to do more than remove the irregular straggling growths. If, however, they require to be cut hard-in and so that little beyond bare stems would be left, they would not start sufficiently this season to make their appearance presentable. In that case it would be best to postpone the pruning until the end of April, or beginning of May.

Hoya carnosa Blooms Falling (*E. S., Chelsea*).—The falling of the blooms may be due to want of water at the roots, but we think it has been occasioned by the soil becoming sodden and sour from excessive waterings in winter, which would cause the roots to perish. Without any information as to the plant's treatment, we cannot arrive at a conclusion nor advise.

Gloxinia's Flower Buds not Expanding (*South Wales*).—The buds have had the corolla destroyed by allowing water to stand in them. It may have been a result of syringing, or of condensed moisture, and the sun's rays falling powerfully upon them whilst wet. The only remedy will be shade from bright sun, keeping them rather near the glass, and preserving a moist atmosphere by frequent sprinklings of the paths, walls, &c., avoiding wetting the plants overhead. You will, we think, yet have a good bloom. The white woolly-leaved plant is, we think, Gnaphalium lanatum; the blue is a Nepeta, but we are unable to say which from so small a specimen.

Herbaceous Plants (*Q. Q.*).—You will find lists of them with their heights, colours of flowers, and usual time of flowering, at page 40 of Vol. XIII., New Series, of this Journal.

Names of Fruits (*J. R. F.*).—No fruit is more difficult to identify than the Strawberry, there being so many varieties, and the difficulty is increased, when, as in your case, their surface has been rendered pulpy by long travelling in contact with wet leaves. The two very fine berries you have sent, we believe—we are not certain—to be Sir Harry.

Names of Plants (*W. B.*).—Your Orchids are both forms of Orchis latifolia, and only differ in colour. (*Annie Heyton*).—2, Lonicera Ledebourii. (*Tyro—W. C.*).—Colutea arborescens, the Bladder Senna. (*F. P.*). 1, Polygonum convolvulus; 2, Solanum Dulcamara; 3, Centranthus ruber. (*Margaret*). — 1, Lonicera Ledebourii; 2, Rhododendron hirsutum; 3, Thalictrum flavum.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending June 29th.

POULTRY, BEE, AND PIGEON CHRONICLE.

THE EAST INDIAN BREEDS OF GAME FOWLS.

The Indian breeds of Game fowls are not very dissimilar to our own birds, though not so symmetrical, so neat, or so clean in limb and in feet. As to size, they vary like our own Game fowls, and are of much the same average size. They are, however, rather more of the Malay type, and more resemble the Malays, especially the smaller ones, than our birds do, but are perfectly distinct from them, having more of the Game shape, and being less stilty or long on the legs than the Malays. Some writers term the Indian Game fowls a smaller breed of the Malays, but any judge of fowls with a good eye can easily distinguish between the Indian Game fowls and the Indian or any other Malays; in fact, they resemble the wild Gallus ferrugineus in most respects, much more than they do Malays, though, of course, larger than the wild aborigines, considerably smaller than the larger Malays, and much more symmetrical in form than any Malays ever are. They are of good courage, which Malays are not, as may be seen on reading Col. Mordaunt's account of them, as he in 1827 took out English Game cocks to India on purpose to try the courage of the Indian Game breeds, and his birds were well beaten by them, probably owing to his cocks having suffered much from the long sea voyage to India, nearly six months, I believe. The courage of the true East Indian Game breeds is as well known in India, as the cowardice of the Indian Malay breeds is.

The Indian Game fowls which I have seen and heard of are of five distinct shades of red. I have also seen the yellow-legged Duckwings at Batavia, in Java, while I was there in 1849, but as these are not considered anything more than a cross-breed, I shall not enumerate them as a sort. I saw no Duckwing hens, but only the cocks, which strongly resembled our smaller yellow-legged Duckwing Game cocks in all respects, shape and everything.

The five different standard colours I will enumerate as follows:—

1st. Black-breasted Reds.—Eyes red, or reddish in general, the legs generally yellow, but sometimes yellowish-green or yellow-willow. General colour of cock much resembling our own birds of this colour. Hen partridge colour, with fawn breast invariably—no other colour.

2nd. Ginger Reds.—Eyes red, or reddish in general, the legs yellow in general, but sometimes yellowish-green or yellow-willow, as in the above. Cock a ginger-red colour, with a reddish ginger breast. Hen a reddish light partridge ginger, with a ginger breast—not fawn-coloured. There are no cinnamon or wheaten hens in this breed, which is closely allied to the first named.

3rd. Gingers.—Eyes yellow or daw always; legs always yellow; the colour a very yellow ginger colour, scarcely red at all. The hen of a light yellow ginger, not a red ginger; light ginger breast. This breed resembles the smaller Malay breeds more than the others.

4th. Brown-breasted Dark Reds.—Eyes very dark brown, bold and full. Comb and face inclining to gipsy in the cock, and quite gipsy-purple in the hen. Cocks of a dark brown-red plumage, with a red-brown breast, streaked with darker brown

or clear red brown. Legs dark willow colour. Hen of a dark pencilled dusky brown, with a streaked dark breast.

5th. Ginger Brown Reds.—Eyes as in the preceding sort; comb and face also. Cocks of a ginger brown-red colour, with ginger breasts streaked or clear. Hen of the same colour but lighter altogether than the preceding sort. Legs dark willow. The two last-named sorts are never yellow legged, but always dark willow-legged.

In the two sorts first named the combs are reddish, but not so red as in our red-combed breeds of Game. In the Gingers, the combs are of a yellowish colour, scarcely red at all, and the last two sorts are invariably gipsy-combed. I should also have stated that in the Black-breasted Reds, so called, the cocks are often mottled-breasted, or pheasant-breasted, instead of black, and that in the Gingers there are both black-breasted light ginger cocks, and the true light ginger-breasted ginger cocks. The three first-named sorts are much the most common, and the two dark-combed and dark-legged sorts much the rarest.

It will be seen that these birds are of precisely the same colours as the wild Gallus ferrugineus, and only differ from them in their superior size and fierceness; some, however, have been crossed with the Malays, as is evident from their long and clumsy legs, and their approach to the Malay shape and coarse feather. The yellow legs are much the most common with the Indian Game fowls, and legs of other colours than this appear to be rare; in fact, the yellow leg greatly prevails in all tropical poultry, a fact which militates greatly against their originals having been solely a dark or darkish-legged breed, as Gallus ferrugineus minor is described as being. I am convinced that the true original of the tropical breeds of poultry must have been the small Red-Brown yellow-legged breed, rather superior in size to the dark-legged Gallus ferrugineus. I am also convinced that the original of the non-tropical breeds of poultry was a brown or horn-coloured legged breed of Gallus ferrugineus which once extended farther north and west of India in Western Asia, and which has now become extinct in those countries. When they were more thickly wooded and less peopled, it was certainly once to be found there, as well as in the East Indian Peninsula, and to 9° or, perhaps, 10° north of the tropic of Cancer.

In the Black-breasted cocks of both Indian Game and the wild Jungle cock, it is to be observed that the breast is always of a greenish black or black with green reflections, and that the black breast with the bluish tinge, or with blue reflections, is never found in any Indian birds as it is in our own Game fowls, and the bar across the wing is invariably of a metallic green in the Indian breeds, and never steel blue, as often found in our own Game fowls. Many of our Game cocks have, however, the greenish tinge on both wings and breast, as is well known, but the breeds with the bluish-tinged breast and wings are generally considered to be our best Black-breasted Red cocks, which are thus distinguished from and differ from the favourite East Indian colour for the breast and wings; our breeds or strains with the greenish-tinged breasts and wings, thus inclining rather more to the original wild or East Indian type.

The five shades of colour described as belonging to Gallus ferrugineus, and to the East Indian Game breeds are, no doubt, the original and standard colours of our own Game breeds in this country, and all the other different strains and shades of colour found amongst our English Game breeds, have been made by different crosses and mixtures, and by breeding in-and-in from these five colours, two of which the Black-breasted Reds, and the Brown Reds are most common with us.—Trevor.

SPALDING EXHIBITION OF POULTRY, PIGEONS, AND RABBITS.

This year's Exhibition was evidently a great improvement on those preceding it, the arrangements being excellent throughout. The poultry Show was held under a tent, 140 feet long, by 40 feet in width, and the comforts of the poultry could not be better provided for. A floricultural show of very high character was also held in conjunction under a tent of precisely similar dimensions. We refer to the minute particulars as to these tents, as it may prove of interest to many other committees that purpose holding similar meetings. All persons well conversant with the management of such shows, know how ruinous to the exchequer is the occurrence of wet weather, and many an excellent show has been completely ruined by consecutive years of unfavourable weather. It is evident these mishaps may be readily and inexpensively provided against, as we are informed not only this pair of gigantic tents, but also a smaller one for the purposes of the Committee, are provided, erected, and taken down by Mr. Wright, the tent maker, of Peterborough, for an outlay of only £12. This includes all outgoings, for there are "not any extras. *Dorkings* were the first class of this Show, good throughout, but many sadly-diseased feet were to be found amongst otherwise excellent stock. *Game* fowls stood next on the list, and here two pens of the best birds were compulsorily disqualified from the owner transposing either the labels or the birds themselves when transmitting them to Spalding. It is somewhat surprising when old well-practised hands commit this somewhat common blunder, and one which as inevitably brings disappointment in its train. The Game classes were very good, a truly splendid pen of Brown Reds, shown by Mr. Gilliver, taking the Game cup. Mr. Mapplebeck had it all his own way in Buff *Cochins*, and Mr. Stephens was far ahead in the Partridge-coloured variety. The *Spanish* were particularly good, and the prizes were closely contested. In *Brahmas* the majority were shown not in the good feather that could be desired, the best-conditioned being decidedly the Light ones as a whole. The *Hamburghs* were not large entries, but mostly of very excellent character. The *Game Bantams* were a large class of good specimens, but many of them were suffering from over-exhibition. The Black Bantams were capital. *Pigeons*, *Rabbits*, *Canaries*, and fancy living foreign birds, added very much to the attractiveness of this meeting, and, perhaps, there has never in this district been so well selected an Exhibition, or one better supported by the public.

(*From a Correspondent.*)

The *Pigeons* formed a grand feature of the Show, both the Carrier classes being commended by the Judge. The cup was awarded to Mr. Fulton's Black Carrier cock, a bird remarkably good in head and eye, and exhibiting true Carrier style. This well-known exhibitor took the prizes in Pouters and Tumblers, in by no means a poor competition. Barbs, Jacobins, Owls, and Fantails, formed excellent classes.

Cage Birds brought a good entry. Mr. Harrison, formerly a resident in this town, and now an extensive dealer in the west end of London, exhibited cages containing six distinct varieties of foreign birds, winning all the prizes in this class. One cage containing some beautiful specimens, was mounted with two globes of gold fish. Great credit is due for the manner in which these specimens were shown.

Rabbits were not numerous, but very good Lop-eared, Himalayan, and Silver Grey were shown. The class for weight contained some large and heavy animals.

Altogether this, the third Exhibition, was in every way a great success; both exhibitors and visitors owe their thanks to the Hon. Sec., Mr. Cammack, for the very able manner in which he carried out his arrangements.

Dorkings (Any variety).—1 and 2, H. Lingwood, Barking, Needham Market. 3 and *hc*, Mrs. Arkwright, Etwall Hall, Derby (Coloured). *c*, Dr. Campbell, Brentwood (Coloured); Rev. G. Hustler, Stillingfleet Vicarage, York.

Game (Black and other Reds).—1 and Cup, W. Gilliver, Polesworth, Tamworth (Black Red). 2, H. M. Julian, Hull. 3 and *hc*, H. E. Martin, Sculthorpe. *c*, S. Matthew, Stowmarket.

Game (Any other variety).—1, H. M. Julian (Duckwing). 2, W. Gilliver (Piles). 3, S. Matthew (Piles).

Cochins (Buff).—1, Cup, and 2, H. Mapplebeck, Woodfield, Moseley, Birmingham. 3, and *hc*, Henry Lingwood. *c*, R. W. Richardson, Beverley.

Cochins (Any other variety).—1, J. Stephens, Walsall (Partridge). 2, H. J. Godfrey, Hammersmith (Black). 3, G. Shrimpton, Leighton Buzzard (White).

Brahmas (Dark).—1 and Cup, C. Layland, Morris Brook, near Warrington. 2, E. Leech, Rochdale. 3, H. Dowsett, Fleshey, Chelmsford. *c*, Rev. H. Combe, Aylesbury; W. Plowright, Spalding.

Brahmas (Light).—1, H. Dowsett. 2, J. Pares, Postford, Guildford. 3, W. Whitely, Sheffield. *hc*, T. Hardy, Peakhill.

Spanish (Any variety).—1 and 2, T. C & E. Newbitt, Epworth. 3, J. Stephens, Walsall. *hc*, J. Laming, Spalding; A. Cole, Long Sutton (Black); J. F. Dixon, Colgrave, Notts; P. H. Jones, Fulham. *c*, J. Mansell, Longton; H. Hendley.

Hamburghs (Gold-pencilled).—1, J. Laming. 2, W. K. Tickner, Ipswich. 3, T. F. Upsher, jun., Sutton, Cambridgeshire.

Hamburghs (Silver-pencilled).—1, J. Laming. 2, A. Woods, Sefton, Liverpool. 3, G. Clarke.

Hamburghs (Gold-spangled).—1, Miss C. E. Palmer, Lighthorne, Warwick. 2, J. Rollinson, Lindley, near Otley. 3, J. Laming. *hc*, J. Barnes, Spalding. *c*, T. Walker, jun, Denton.

Hamburghs (Silver-spangled).—1 and Cup, J. Laming. 2, T. Walker, jun. 3, J. Tooley, Downham Market. *c*, A. Storrar, Peterborough.

Polands (Any variety).—1 and Cup, J. Laming. 2, W. H. Patrick, Lynn (Gold).

French Fowls (Any variety).—1, H. Wyndham, Beverley. 2, P. H. Jones. 3, W. Tippler, Chelmsford (Houdan).

Any other Distinct Variety not Previously Mentioned.—1, J. Laming. 2, T. Spurr, King's Lynn (Japanese).

Game Bantams.—1 and 2, W. F. Entwisle, Leeds (Black-breasted Red). 3, W. Adams, St. Clements, Ipswich. *hc*, J. Eaton, Farnsfield, Notts (Black-breasted Red); H. Headley; G. Maples, jun, Wavertree. *c*, J. Laming; H. Eggleston, Halifax; J. R. Robinson, Sunderland.

Bantams (Any other variety).—1, A. Storrar, Peterborough (Black). 2, Mrs. Woodcock, Leicester (White Japanese). 3 and *hc*, S. S. Mossop, Long Sutton. *c*, J. Laming; J. H. Dawes (Japanese).

Selling Class (Any variety).—1, R. Clement, Spalding (Black-breasted Red Game). 2, J. Laming (Game). 3, C. W. Gibbs, Sutton Marsh (Golden Hamburghs). *c*, W. Tippler (Buff Cochins).

Ducks (Rouen).—1, E. Leech. 2, T. F. Upsher, jun., Sutton, Cambridgeshire. 3, Withheld.

Ducks (Aylesbury).—1, W. Tippler. 2, W. N. Hunt, Deeping, St. Nicholas.

Ducks (Any other variety).—1, S. & B. Ashton, Mottram (Garganey Teal). 2, R. W. Richardson. 3, Withheld.

FARMYARD.—1, R. W. Smith, Granford, March. 2, R. Webster, Weston, March.
GEESE (Any variety).—1, Rev. G. Hustler. 2, Mrs. Sewell, Pinchbeck.

PIGEONS.

CARRIERS (Any colour).—1, Cup, and 2, R. Fulton, Deptford. Whole class commended.
CARRIERS.—1, R. Fulton. 2, E. Walker. Whole class commended.
POUTERS (Any colour).—1 and 2, R. Fulton. *hc*, P. H. Jones, Fulham; R. Fulton.
POUTERS.—1, 2, and *hc*, R. Fulton.
TUMBLERS (Almond).—1 and 2, R. Fulton.
TUMBLERS (Any other variety, Short-face).—1, 2, and *hc*, R. Fulton (Mottles and Short-face). *c*, P. H. Jones (Kites).
BARBS (Any colour).—1, W. Massey, Spalding (Black). 2 and *hc*, P. H. Jones. *c*, H. Yardley.
JACOBINS (Any colour).—1, J. Hawley, Bingley. 2, T. C. & E. Newbitt.
FANTAILS (Any colour).—1, J Hawley. 2, W. H. Tomlinson, Newark (White). *hc*, H. Sunshall, Fleet Hargate; T. C. & E. Newbitt. *c*, H. Headley.
TURBITS (Any colour).—1, P. H. Jones. 2, H. Yardley.
OWLS (Any colour).—1, J. Fielding, jun., Rochdale. 2, P. H. Jones. *hc*, T. Egglestoo, Halifax.
DRAGOONS (Any colour).—1, J. Hawley. 2, P. H. Jones.
ANY OTHER DISTINCT VARIETY.—1, J. Hawley. 2, W. Woodhonse, West Wioch, Lynn.
SELLING CLASS (Any variety).—1, H. Snushall (Victorias). 2, Hudson and Burnip, Epworth.

CAGE BIRDS.

CANARY (Belgian).—1, E. S. Smith, Boston. 2, Miss E. M. Maples.
CANARY (Norwich).—1, W. Woodhouse. 2, J. W. Harrisoo, Great Portland St., London.
CANARY (Mule).— 1 and 2, W. Woodhouse. *hc*, J. W. Harrison.
LINNET, GOLDFINCH, OR OTHER ENGLISH FINCH.—1, W. Woodhouse (Goldfinch). 2, E. S. Smith, Boston (Goldfinch). *hc*, H. Harvey, Spalding (Bullfinch). *c*, R. Judd (Brown Linnet).
LARK.—1, J. A. Eaves, Skirbeck, Boston. 2, E. S. Smith.
THRUSH.—1, R. D. Borne, jun, Boston. 2, E. S. Smith.
BLACKBIRD.—1, E. S. Smith. 2, R. D. Borne, jun.
PARROT (Grey).—1, P. Goodacre, Boston.
VARIEGATED PARROT, PARAQUETTE, LORRY, OR OTHER FOREIGN BIRD.—1, G. E. Storr, Spalding (King Parrot). 2, T. Goodacre (King Parrot). Extra 2, H. Dodson, Moulton (Australian or Shell Parrots).
BEST COLLECTION OF SMALL BIRDS.—1, 2, and *hc*, J. W. Harrison (Foreign and British Birds).

RABBITS.—*Heaviest.*—1, W. Jeffrey. 2, P. Booth, jun., Spalding. *hc*, T. Mumby, Loog Suttoo. *Lop-eared.*—1, B. Hudson, Hull. 2, A. H. Easten, Hull. *Fancy Variety, except Lop-eared.*—1 and 2, A. H. Easten (Silver-Grey and Himalaya).

The *Poultry* were judged by Edward Hewitt, Esq., of Birmingham, and the *Pigeons*, *Rabbits*, and *Foreign Birds* by Matthew Hedley, Esq., of Claremont, Surrey.

BARNSTAPLE POULTRY SHOW.

THE following is a list of the prizes awarded at this Show, held on June 23rd and 24th.

COCHIN-CHINA.—1, J. Beard, St. Blazey. 2, J. H. Dawes, Moseley Hall *c*, W. L. Trewin, Kilkhampton.
BRAHMAS.—1, L. H. Ricketts, Bemvell. 2, H. Day, Ilfracombe. *c*, S. R Higham, Morehard Bishop.
MALAY OR INDIAN GAME.—1 and 2, H. Darch, Stratton, Cornwall.
GAME (Black-breasted Reds).—1 and 2, Rev. G. S. Cruwys, Cruwys Morchard.
GAME (other Reds).—1, E. C. Pope, Falmouth. 2, J. Westacott, Barnstaple.
GAME (Any other variety).—1, Rev. G. S. Cruwys. 2, Withheld.
DORKINGS (Coloured).—1, G. N. Walsh, Halsden, Dolton. 2, S. Woodman, Barnstap e.
DORKINGS (White).—1, Withheld. 2, Mrs. Hartwell, Pentra.
SPANISH.—1, Tonkin & Tuckey, Bristol. 2, W. Nosworthy, Exeter.
MINORCAS (Red-face).—1, F. Brewer, Lostwithiel. 2, F. Gloyn, Bridgerule. *hc*, H. Leworthy, Newport, Barnstaple.
ANDALUSIAN (Blue, or Blue Pilea).—1, J. Perrien. 2, W. Harper.
ANCONAS.—1 and 2, Miss C. E. Leworthy, Newport, Barnstaple.
FRENCH.—1, J. F. Worth, Washfield. 2, Miss B. W. Baring. *hc*, F. Brewer.
POLANDS.—1, Mrs. E. Procter, Hull. , J. Beard. c, M. A. Sly, Albaston.
HAMBURGHS (Golden-pencilled).—1, H. A. Carvannel, Redruth. 2, S. R. Harris, Cusgarne, St. Days. *hc*, F. Perren, Bristol. *c*, J. H. Nicholls, Lostwithiel; J. Stevens, Bideford.
HAMBURGHS (Silver-pencilled).—1, S. R. Harris. 2, J. Walter, Bideford.
HAMBURGHS (Golden-spangled).—1, J. Medway, Newton Abbot. 2, Miss S. E. Delmar, Trelana, Bude.
HAMBURGHS (Silver-spangled).—1, S. R. Harris. 2, E. C. Pope.
ANY OTHER NEW OR DISTINCT VARIETY EXCEPT BANTAMS.—2, T. Sherston.
GAME BANTAMS.—1, W. Dale Weston-super-Mare. 2, F. Brewer. *hc*, Master Williams.
BANTAMS (Any other variety).—1, Rev. G. S. Cruwys. 2, S. Woodman, Barnstable. *hc*, Rev. G. S. Cruwys. *c*, Tonkin & Tuckey; Rev. G. S. Cruwys; R. L. Hole, Hannaford, Swiabridge.
TURKEYS.—1 and 2, L. Pattoo, Hillmore, Taunton. 3, J. Heal, Parkham.
GUINEA FOWLS.—1, T. Hill, Marwood. 2, H. Adney, Pemberton, Collumpton.
GEESE (Toulouse, Embden, or Farmyard).—1 and 2, J. Heal. 3, H. Adney.
GEESE (Any other variety).—1 and 2, Mrs. Brayley, Swinbridge.
DUCKS (Rouen or Aylesbury).—1, L. H. Ricketts. 2 and 3, L. Patton.
DUCKS (Any other variety).—1, J. Oliver, Bideford.

PIGEONS.

CARRIERS.—1, C. Bulpin, Bridgewater. 2, G. S. Hockey. *hc*, J. Davy, Bideford; G. S. Hockey.
POUTERS.—1 and 2, C. Bulpin.
TUMBLERS (Almond).—1, Master C. W. Bulpin. 2, H. Yardley.
TUMBLERS (Any other variety).—1, Master C. W. Bulpin. 2, W. Westacott, Barnstaple.
BARBS.—1 and *c*, F. L. Smith, Newport. 2, H. Yardley.
JACOBINS.—1, C. W. Bulpin.
OWLS (Foreign).—1, C. Smith. 2, C. Bulpin, Newport.
FANTAILS.—1 and *hc*, Mrs. Bulpin. 2, H. Yardley.
OWLS (English).—1, W. Westacott. 2, Master Bulpin.
TRUMPETERS.—1, Miss F. M. Bulpin. 2, J. A. Sleath, Newport.
TURBITS.—1, H. Yardley. 2, C. Bulpin.
NUNS.—1, C. Bulpin. 2, H. Yardley.
ANY OTHER NEW OR DISTINCT VARIETY.—1, H. Yardley. 2, A. Garnish, Chittlehampton Vicarage. *hc*, Mrs. Bulpin. *c*, E. S. Keall, Ilfracombe.
CAGE BIRDS.—1, N. Robbins (White Mule); Mrs. Petherbridge, Barnstaple (Parrots). 2, J. Galliford, Lake, Tavistock (Lark).

JUDGES.—Dr. Scott, and the Rev. G. F. Hodson.

A LITTLE ADDITIONAL PIGEON LORE.

BEING something of an archæologist, and very much of a Pigeon-fancier, I was particularly interested in the article in last week's Journal, entitled "Poultry and Pigeon Lore," and beg a place for the admission of the following:—The Rev. A. C. Smith, in his ornithology of Wilts, published in "The Wilts Archæological and Natural History Magazine" of May, 1868, states: "There are instances of the lower stage of church towers, immediately below the bells, having been originally built for a columbarium, of which we have one example at Collingbourn, in this county, and probably there may be others of which I am not aware. Another instance occurs at the tower adjoining the ruined chapel of Charter House, Hinton, near Bath, the lower part of which was originally intended for the priest's residence, and the birds dwelt above him. In both these cases the east, north, and west sides are fitted up with Pigeon holes, and a small square opening in the south wall admitted the birds."

Perhaps some of my brother clerical readers may know of other instances; if so, I should be very glad to be informed of them.—WILTSHIRE RECTOR.

MORTALITY AMONG CANARIES.

YOUR correspondents "ONE IN A FIX," and "A SUBSCRIBER" are not alone in their troubles. The bills of mortality in the Canary would only too frequently tell of this species of murrain. There must be a cause for it, finding its origin in the violation of some law, but which nevertheless may still be beyond our knowledge, and consequently beyond our control. It is by no means unusual to hear of an entire stock being almost annihilated. When I first began to breed Canaries I put up eight pairs, and at the close of the season I had just three birds. Every old one was dead, and all the young stock except these three, and from no cause which I could in the least degree trace. All died from apparently the same cause, exhibiting the same symptoms, and dropping off slowly, but surely, one by one. The next season, under precisely similar treatment, with the same diet, and in the same room I have reared a great number, nor have I had any recurrence of such a visitation. Should there be, I shall be as powerless under it as "SUBSCRIBER" or "ONE IN A FIX." The farther we depart from Nature, and the more we try to reclaim and tame (I was going to say civilise), and domesticate birds, the more difficult becomes the task; for the more liable we become to exact so mething from them which violates some important condition of their existence, or at least of their health, and we know what inevitably follows.

I can see nothing to find fault with either in the diet described or the general mode of treatment. It is in the main the same as I follow myself, and I do not attribute the loss of a "SUBSCRIBER'S" young ones to any defect in these particulars, but to something radically wrong with the hens—they are the nurses and feeders, and the general management of the young brood devolves upon them. True, the cock bird feeds the young and, as a rule, feeds them well, and goes through a few other motions in his own peculiar, affectionate, clumsy, left-handed way, standing over the young ones with his legs wide-stretched, evidently quite under the impression he is keeping them warm and doing something very clever; but it is the hen who determines when they shall be fed, or whether they shall be fed at all; she nurses them, and attends to their little wants, and tucks them up in their warm bed after each meal, while the old cock looks on very patronisingly, as if the whole affair was under his direction; then off he hops to the egg box, and back to his hen, and off to the egg box again, hop, step, and a

jump, like a feeding machine, and the young ones have hardly had time to compose themselves for forty winks after their last meal before the cramming process is repeated. So long as this machinery works well, all goes on well, but if from any cause the hen become sick or out of condition, visible or otherwise, at once the young ones begin to decline; a retrograde movement begins, which most certainly ends in the loss of the whole nest. When a nest of fine, plump, healthy, lusty young birds, such a nest as I cannot describe, but which every breeder full well understands, once begins to lose that appearance (and a practical eye can at once detect it), it is a saving of time, a service to the old birds, and a happy release to the young ones, to nip their necks, unless they can be at once transferred to another more healthy nurse. To the uninitiated this may seem cruel treatment, but in the long run it is the most merciful. The first forty-eight hours of a young bird's life are very important ones, if well fed then you may hope for size and health; but if only nursed in a step-mother sort of way, it never seems to recover the neglect, and at best grows up a dwarf. "Never crow till you are out of the wood." The man who first said that, must have been in the "fancy." It means, Do not count your young birds till they are sitting on the edge of the nest; then do so with fear and trembling, but hold them with a light hand till they are on hard seed. Notice carefully every day if any in the flight cages look puffy, or sit thick. I have called attention to this once before, but some may have overlooked it, and it may be of value just now to know that the best treatment in such cases which arise from a disordered state of the bowels, and digestive apparatus generally, is to administer a good dose of castor oil. I put my stick well down into the bottle to ensure its holding sufficient, and allow the bird to swallow not less than three good drops. Its action is quick and effectual. Put the invalid on ground canary seed, mixed with maw seed, and in place of an emaciated sufferer you will in a few days find him as plump as ever.

"Subscriber" should continue with the Diamond Finch as he has been doing. Nature will, however, do most to assist the bird in getting rid of the swellings.—W. A. Blakston.

NEEDLESS DESTRUCTION OF BEES.

The first week in June we had a small swarm which we lost for that day, but found in another part of the garden the next morning, I hived them and they appear to be doing well. On the 8th we had another small swarm, so I thought I would unite them to the other of the week before, which I did the same evening. All appeared to go on well till Friday the 19th ult., when I saw outside the hive a number of dead bees. On the 20th I raised the hive to examine them, when I found more than half the bees dead on the floor, and those alive all very weak. They had made a considerable quantity of comb which was much discoloured, and in several parts full of either a small white maggot or in others of a dark brown grub. The whole had an unpleasant smell; now, fearing this was the foul brood I have read of, I thought it best to destroy them all, so I poured over them some boiling water and destroyed the hive. Did I do right?—Thomas Comber.

[You did right in uniting the two small swarms, but wrong in destroying them, as they were simply dying of starvation arising from the late unseasonable weather, and might have been saved by a little timely assistance in the shape of food. The maggots and grubs were the brood of the bees, and were doubtless in a perfectly healthy condition.]

HONEY CONSUMED—DRONES.

We have a hive of bees twelve months old. We know that they have swarmed once, and we think they have swarmed twice. A few days ago the outside comb next the glass window was full of honey and sealed over; it is now all gone, and the hive appears to be three-parts full of drones. Is there any means to destroy a portion of them? They appear to be so strong in numbers that they will consume all the honey.—W. Strettle.

[When bees swarm they always fill themselves with honey, and this has, doubtless, had more to do with the rapid consumption of honey than the presence of drones, although the latter are unquestionably good feeders. The workers will soon expel them when their office is accomplished and the young queen begins egg-laying, and you had better leave it to them.]

OUR LETTER BOX.

Food for Fowls (*A. B. C.*).—We have many times tried to explain, and do so again, that we cannot name any quantity of food as sufficient for a number of poultry. It is guided by many things, as, for instance, the nature of the run they use, their condition and health, their breed. You are as well able to form your conclusion as we are to advise you. Feed them by hand, and with measured food. Keep account of the consumption, and after one week you will be able to judge for yourself. If they are in bad condition when you begin, they will consume more at first, as they have to make up condition, after this is accomplished there should be little variation. A grass run is one-third food, and with Geese one-half. Ducks and Geese do best on oats. Fowls want ground oats and barley, varied at times with whole corn and maize.

"Poultry-keeping for Profit—Gapes (*H. J. C.*).—As you speak of the market, we presume you mean to breed for the table. In such a situation as you describe, we should advise you to keep Brahma Pootras. They are hardy and profitable. No really adult fowls lay in the winter months. To ensure eggs during December and the following two months, you must keep early pullets of the previous spring. Most fowls prefer to roost in trees, and during the summer they do, we think, better there than elsewhere. In the winter the house is better and safer for them. Grass is a far better run than gravel, and in an orchard you will find the hens clever at making dusting places round the stems of the trees. Gapes are cured by giving one or two pills of camphor the size of a pea, and by giving them strongly camphorated water to drink.

Eggs Unproductive (*H. B.*).—It is so manifestly against the interest of those who make egg-dealing a profit to send out stale eggs, or those about which they have any doubt, that we should not think either of the persons you mention would do so. We think you might fairly appeal to both of them. We are disposed to doubt the close sitting of the hens; had they done so, the eggs being damped should have produced all the chickens and ducklings, if not at once, certainly within a few hours of each other. It is not necessary to damp the eggs at first, but for ten or twelve days before hatching; and we think the exit of the chickens is facilitated by the eggs being left in warm water for ten minutes when they are tried a day or two before they are expected to hatch.

Game Bantams at the Thorne Show.—We are informed that Mr. J. Crosland, jun., won the cup as well as the first prize.

Lice on Poultry (*W. W.*).—Dust flowers of sulphur under their feathers, so as to reach the skins of the fowls. Mix flowers of sulphur plentifully in the dust heap where they bask. Let the nests be made of fine deal shavings, and let the young chickens rest at night upon the same kind of shavings. The vapour of turpentine from the shavings is fatal to lice.

Ducks Suffering from Cramp (*Henwife*).—We fear you have a bad case. All you can do is to shut them in a dry place, the floor covered with dry straw, and feed on oatmeal put in a shallow vessel with sods of growing grass and some gravel. It is more than probable the Duck has had her liberty, and has dragged them through the grass when covered with dew or white frost. They should not be out till the sun is up and the grass dry.

White Musk Ducks—White Spanish Geese (*R. P.*).—The White Musk Duck is scarce, but seldom wanted. White Spanish Geese are only ornamental.

Weight of Aylesbury Ducks (*J. S.*).—With few and rare exceptions, 8 lbs. form the present limit of weight for Aylesbury Ducks. There have been rare exceptions where they have, when prepared for exhibition, weighed 10 lbs. If we are to understand you mean that when killed they are to be fit for food, then we say 9 lbs. are an unattainable weight. This is the result of especial feeding with a view to produce weight; or of extreme fat, the consequence of old age. In either case, the bird is unfit for food. A few years since 9 lbs. were the average weight of Geese, they are so no longer. We commonly have them 15 lbs. or 16 lbs. We have weighed this morning six unusually fat and fine young Ducks, as fine and large as we ever obtained, two weighed 5¼ lbs. each, two 5 lbs. each, and two 4½ lbs each. It is difficult to obtain them so heavy while they are young and tender. Four pounds would be a large average.

Tumbler Pigeons (*A Young Tumbler Fancier*).—Almost every dealer has "Feather-footed Tumbler Pigeons," now called by them Birmingham Rollers. Choice kinds could be easily obtained by advertising in our columns, by which plan (far easier than by guessing), you could obtain the "Chequered Blue Tumblers, and Barred Blues," which you require. It is certainly best not to keep common birds with flying Tumblers, they bring them down in flight, and injure their tumbling by so doing. Do not cross the common birds with Tumblers Old-established breeds, such as Tumblers, have been raised by care and pains, and it is not well to spoil them, but it is best to preserve them carefully from an admixture of common blood.

Pheasants Suffering from Cramp (*S. B.*).—Nothing is so good as grass to pen hens and Pheasant poults upon, but it should be cut short in the spots where they are put. When many Pheasants are reared, a field should be chosen slightly on the descent, and covered with long grass, but not thick at bottom. This should be cut in squares like a chess-board, the mown parts being for the hens in rips, and the covered parts for shelter for the poults. They also find much food in it. It affords them a shelter from mid-day heat, which is often fatal to them. Stale bread soaked in strong ale is the best cure for cramp.

Rabbits (*Neptune*).—The doe, whose young ones have been destroyed, may be placed along with the buck now.

Gooseberry and Grape Tart.—A lady writes to us that "Green Gooseberries mixed with the thinnings of the green Grape, sweetened with pounded white sugar, make an excellent and agreeably flavoured tart."

Brittany Cows.—"In reply to 'A Subscriber,' these cows are said to be kept for less than any other variety, and in proportion to their size, give richer and more milk. I have not had mine long enough to give a decided opinion, but some of my friends speak highly of them. Your correspondent can purchase them from an importer Mr. Parsons, Yew Tree Cottage, Southgate Road, Winchester, where I purchased mine.—J. W."

WEEKLY CALENDAR.

Day of Month	Day of Week.	JULY 8—15, 1869.	Average Temperature near London.			Rain in last 42 years.	Sun Rises.	Sun Sets.	Moon Rises.	Moon Sets.	Moon's Age.	Clock before Sun.	Day of Year.

14	W	Loughborough Horticultural Show.	74.2	50.4	62.3	15	1 4	10 8	5 10	2 11	5	5 33	195

From observations taken near London during the last forty-two years, the average day temperature of the week is 74·8°; and its night temperature 50.3°. The greatest heat was 93½°, on the 14th, 1847; and the lowest cold 33°, on the 9th, 1863. The greatest fall of rain was 1.10 inch.

DINNER-TABLE DECORATIONS.

AMONGST the many subjects which present themselves to the gardener in the fulfilment of his duties, the arrangement of the dessert and the decoration of the dinner-table, so far as they are in connection with his department, occupy an important position. During the last few years this subject has increased in importance, owing to *diners a la Russe* having become so fashionable. Generally where this fashion prevails pot plants predominate as ornaments for the dinner-table. These, if properly grown, answer very well, but I do not think them so suitable as cut flowers skilfully arranged: but if these are scarce, or their arrangement is not thoroughly understood, then it would be better to employ plants. The characteristics of plants for this purpose should be elegance and lightness, such as we find in ornamental-foliaged plants, as Dracæna terminalis or Dactylis glomerata variegata; and, among flowering plants, in Fuchsias or small-leaved Begonias. A heavy dwarf plant rarely looks well on the dinner-table—I allude to such plants as the large-foliaged Begonias, Gymnostachyum Pearcei, or Fittonia argyroneura; these plants and many others like them, although undoubtedly presenting a novel and beautiful appearance, yet are, I think, much better adapted for the decoration of the conservatory or vestibule. Of course there are exceptions to this rule as to all others. For instance, a Gloxinia amongst stove plants, and a large-flowered or Fancy Pelargonium amongst greenhouse plants, though dwarf, are yet rendered so bright and cheerful by their abundant blossoms that they may well form exceptions; and, again, if during the winter months one or two plants of that lovely stove climber Thunbergia Harrisii be introduced, they are quite certain to be admired. To have neat little half-specimens of this plant in bloom in 6 or 8-inch pots during winter, cuttings should be taken early in May, and grown throughout the summer and autumn in rich sandy loam containing a slight admixture of charcoal.

Whether plants are constantly required for the dinner-table or only for a definite period, as much variety should be secured as possible, and a considerable space of time should intervene between the first and second appearance on the table of the same plants; then, again, fine-foliaged plants should alternate with plants in bloom. I have known great annoyance given by a constant succession being kept up, night after night, of ornamental-foliaged plants, such as Begonias, Caladiums, Dracænas, and Crotons; always a fresh variety, but foliage, ever foliage. Now this was certainly a mistake, unless there had been an expressed wish; for, however rich and varied may be the colour, and however singular the variegation of the foliage, yet leaves must ever give place to those lovely tints and that delicate freshness which are the peculiar properties of blossom.

Crotons and all other fine-foliaged plants possessing yellow leaf-markings should be rarely introduced, as they never "light up" well, however beautiful they may be when seen by daylight; the yellow variegation, which is their chief beauty, loses so much of its richness by lamplight as to cause the entire plant to appear very insipid. Pink, on the contrary, acquires a deeper hue and richer charm from artificial light. I know no plant so charming, when seen in this way, as a deep pink Primula sinensis; its cheerful blossoms coming to us during the dullest season of the year ever receive our warmest welcome, but it is at night that they appear to partake of the greater sociability of humanity which is inspired by the exclusion of the external cold, by the drawn curtains, and the glowing fire; then they offer themselves to our gaze with a warmth and richness of colour which render them most attractive.

Plants, then, it must be granted, possess many advantages over cut flowers for dinner-table decoration, yet for the centre of the table nothing, in my opinion, can equal in appearance an epergne dressed with choice cut flowers and foliage, with the occasional addition of a few carefully selected examples of fruit. I have also seen small epergnes containing nothing more than Black and White Grapes, skilfully intermixed with Vine leaves and tendrils, which had a very good effect. Vases of cut flowers for this purpose are always appreciated, if they are suitable in design and size.

In setting up the fruit, if flowers are used, the simplest and most effective method is to arrange the latter in the form of a wreath. These wreaths should be just visible over the edges of the dishes, and rest lightly and gracefully against the lowest tier of fruit. A good wreath for a dish of dark-coloured fruit is formed of shoots of Cerastium tomentosum with single flowers of Campanula, used in just sufficient quantity to relieve the sameness of the grey; fresh young shoots of variegated Pelargonium Dandy, intermixed with either pink or blue blossom, are also good; and small leaves or shoots of Pelargonium Italia Unita form a lovely wreath. For fruit of a lighter colour, shoots of Begonia fuchsioides interspersed with its unopened heart-shaped blossoms form a good wreath. Then, again, small fronds of Maiden-hair Fern, with the deep crimson flowers or seed-vessels of Chenopodium atriplicis are very beautiful.

Although I have thus enumerated a few suitable wreaths, yet the plants offering materials for this purpose are so numerous as to render it useless to endeavour to form any regular list. Each season of the year, in fact, offers materials for wreaths peculiar to itself; for instance, early in spring, how chaste and elegant is a wreath of the fresh young shoots of the common Laurel regularly interspersed with its pure white blossoms! or a wreath of the foliage and blossom of any of the Myosotis family, or the tips of the young shoots of the Spruce Fir, dotted with the pink blossoms of the Larch. All such materials are of the simplest description, hence their suitability for the purpose.

One other point must be remembered, which is, that no flowers possessing the slightest offensive odour should be used, for no matter however well adapted they may otherwise be, yet should they impart the slightest un-

pleasantness to the flavour of the fruit they will only tend to mar the enjoyment of those for whose pleasure they were provided.—Edward Luckhurst, *Egerton House Gardens, Kent.*

JUSTICIA SPECIOSA CULTURE.

When well-grown, this is a fine showy plant for decorative purposes. By pinching at regular intervals, it assumes a sturdy and compact habit of growth, and when placed in the most favourable position during growth, and in suitable soil, its foliage becomes large, and of a rather dark green, which sets off to advantage the numerous purplish flowers.

Being a native of the East Indies, the plant requires heat to grow it to perfection; but in this respect it is very accommodating, for it will thrive in a much milder temperature than many cultivators give it—indeed, the strong heat in which it is generally kept is, in my opinion, one of the errors which are committed in its culture, for when so treated the plant is slender-stemmed, long-jointed, and produces few flowers, which last only a short time; indeed, under such treatment it is anything but the beautiful and continuous-flowering plant it is when grown under the system which I shall describe.

The principal time for the plant's flowering is stated in the "Cottage Gardeners' Dictionary" to be the month of August; but I am in the habit of growing it for conservatory decoration, and of having it in bloom in the winter months. For this purpose I insert the cuttings in sandy soil in heat during the first week in May; when struck, I select the best and pot them off in large 60-sized pots, using at this early stage a soil of moderate richness, such as turfy loam (not light), and leaf mould, with a little sand. After a few days take the top out of every shoot, and when they break again they will require a further shift into 6-inch pots. From the time the cuttings are put in, up to this stage, they should have a regular heat of 60°, plenty of moisture at the roots and in the atmosphere, and plenty of light; shading, however, from very bright sun.

After the young plants have become established they may with advantage be transferred to more airy quarters, where they will have plenty of light as before; but instead of using fire heat, unless the weather is unseasonable, they will do much better if the house or pit be shut up early to secure sun heat. Syringe copiously, stop the shoots as required—every one, large or small. This insures more perfect blooming. Shift the plants this time into pots of the next larger size, using stronger and richer soil; and as the Justicia is a vigorous-rooting plant, it must have plenty of moisture, consequently plenty of drainage. Shift the plants again when necessary into 9-inch pots, stop them once afterwards; then they may be allowed to grow at will, complete their growth, and form their flower buds. While these are becoming developed, gradually give more air, which will so far harden the plants as to enable them to flower in perfection in the more intermediate temperature of the conservatory.

Under the above treatment the plants will generally be about 2½ feet high, and 18 inches in diameter; but if taller plants are wanted they may be grown in stronger heat and pinched less frequently; still, as before stated, such treatment shortens the period of flowering, and deteriorates the value of the flowers for cutting purposes.

After the flowering is over I make it a rule to reduce my stock to two or three plants, which are kept in a rather dry state in the greenhouse through the winter, until wanted to supply cuttings in the spring, when they are cut back and placed in heat. Many cultivators keep their whole stock through the winter, shake the plants out in the spring, cut them back, start them into growth, and shift into larger pots as necessary; but as the Justicias are vigorous-growing, where room is at all valuable, the treatment I first described is preferable.—Thomas Record.

CHRYSOBACTRON HOOKERI.

This member of the Asphodeleæ was introduced into this country in 1848. It was discovered by Mr. Bidwell in rich marshy districts about Wairu, Middle Island, New Zealand. "It grows," said Mr. Colenso, who also discovered it, "in great clumps in boggy places, and is said to cover the plain with a sheet of yellow when in bloom. Some of the masses are 3 feet in diameter." It is figured in the "Botanical Magazine," t. 4602, and is there stated to have been kept at Kew in a cool frame. Probably from being treated too tenderly it was destroyed, for we believe it is no longer in the gardens. It is now called by some botanists Anthericum Hookeri. We are glad to find that it has been re-introduced, for we have received a specimen in flower from Mr. A. Storrie, Whiteinch Nursery, Partick, Glasgow.

He describes it as a hardy herbaceous plant, adding, "I have several plants at present in bloom, and it is thought by some a great acquisition. One plant planted-out two years ago has twenty-six spikes of flowers. The leaves attain 18 inches in length, and the flower-scape 1½ to 2½ feet, or even 3 feet, in height."

ZINC EDGE FOR FLOWER BEDS ON GRASS.

Graceful curvilinear beds on lawns are after a time often much distorted in consequence of the encroachment of the grass round their edges, and without much care in cutting it is almost impossible to keep the original design. I have, therefore, much pleasure in laying before your readers a simple plan to remedy this, and to effect a saving of labour. The thought struck me that some kind of metallic lining would answer the purpose, and about twelve months ago I tried the experiment in my home garden, the result of which is very satisfactory.

The following are the instructions:—Edge round your flower beds with a perfectly even upright cut in the grass, 2 inches deep, and let into this cut a strip of stout zinc of the same depth, bending and fitting it exactly to the shape of the bed on a level with the surrounding grass. To keep the zinc firmly in its place, drive down some small, square, red deal pegs, about a foot apart, making them low enough for the tops to be covered by the soil of the bed. With a little brown paint brush the zinc edge, which should be left 1 inch deep after the soil is replaced. The shape is thus accurately and permanently preserved.

These strips might be painted and sanded on one side before they are put down. They cost about three farthings per foot run, and are cut from 8-feet sheets of zinc of No. 12 thickness. The mowing machine will cut over this edge, and the stray blades of grass that escape can be easily clipped off, so that even a lady gardener with a pair of scissors may keep the edges of her beautiful scrollwork parterres in perfect order.—Henry Curtis, *Devon Rosery, Torquay.*

VICOMTESSE HÉRICART DE THURY STRAWBERRY.

If I were to be asked which is the best Strawberry for general use, I would unhesitatingly name the above. Out of a collection of upwards of five hundred varieties which I have grown and fruited during the last ten years, there is none, not one, to equal this, by far the most useful Strawberry in cultivation. It is surpassed by some in point of size—it is not a monster—by others in point of flavour—it is not a Queen; it is, however, extremely pleasant, and like the Black Hamburgh among Grapes, the most refreshing of all. A few Muscats cloy our palates, a few British Queens satiate us; we come back as to a well of pure water after a feast of wine, to the Hamburgh in the one case, and to the Vicomtesse Héricart de Thury in the other.

The Vicomtesse Héricart de Thury Strawberry is a most extraordinary bearer, the crop produced from a certain number of plants being something enormous. Although few of the fruits exceed the medium size, they are nearly all of good size, and gathering after gathering may be taken, the last almost equal to the first. There is no other Strawberry from which so many dishes of good uniform fruit can be taken as this. It is very unlike Keens' Seedling and many others in that respect, as from these, as is well known, after the first picking the rest are all "chats." Yet even the small fruits of this variety are prized and welcome. To use a Covent Garden expression, "the colour sells it." It is of the brightest and clearest scarlet, and very pleasing in appearance. Through its brightness and fresh appearance it is selected and preferred to others greatly exceeding it in size. This I have often observed in my experience of selling a mixed collection of Strawberries. The surface of the fruit is firm, so that it does not bruise readily; it is an excellent sort for packing and sending to a distance, being as fresh at the end of a day's journey as if newly gathered. This is a great quality in Strawberries, too often overlooked by the introducers of new varieties. Besides its high qualities as

a dessert fruit, it is also one of the finest varieties for preserving purposes, the flesh being of a fine reddish tinge. It also forces well.

In constitution this Strawberry is one of the hardiest and most vigorous, accommodating itself to almost every soil and situation, and rarely, very rarely, being injured by frosts or wet. Its foliage, indeed, remains pure and green throughout the most severe winter; it might be called the evergreen Strawberry. It is on that account very suitable and ornamental as an edging Strawberry in the kitchen garden. It is long-lived, although, as with all other Strawberries, the best fruits are produced on young and vigorous plants. This will continue in bearing on the same plants for many years in succession, longer than any other Strawberry.

In point of earliness, it is a day or two in advance of Keens' Seedling, and continues in bearing a week later than that variety. In form the fruits are generally conical, the largest being cockscomb-shaped.

The Vicomtesse Héricart de Thury is not a new variety. It was brought to this country from the neighbourhood of Paris, where it is esteemed over all other varieties, by Mr. R. Thompson, of Chiswick, many years ago. It has been distributed throughout the country a little, yet through not being directly the property of some pushing nurseryman, it has never obtained that publicity or notice which it would otherwise have done. I have myself sent it to all parts of the kingdom—to the north of Scotland, to Aberdeen, to Yorkshire, to North and South Wales, to Kent and Sussex, and from every quarter the report is the same—"The Vicomtesse Héricart de Thury is the best Strawberry we have." A further proof of its good qualities is its number of synonymes—viz., Duchesse de Trévise, Prince Imperial, Marquise de la Tour Maubourg, &c.—ARCHAMBAUD.

NEW ROSES AT THE ROYAL HORTICULTURAL SOCIETY'S SHOW.

ALTHOUGH I have headed this paper thus, and shall in the main confine myself to my text, yet I should like at the same time to take a little wider range, and include within it, as far as I can, my judgment on the new Roses of 1867 and 1868. I am not likely to see any more of the Hybrid Perpetuals (the Teas I shall reserve for another opportunity), this season, and be it remembered I only give my judgment on what I have seen. I take no *ipse dixit* of anyone, however clever and disinterested he may be. I ask no one to agree with me. I have my own ideas of beauty, and of what constitutes a good Rose; they may be false ones. My Vanessa may be no Vanessa to my neighbour Smith, but that does not prove Smith to be wrong; it only shows that he and I do not think alike.

There were four stands of Roses exhibited in the class for varieties of 1867 and 1868. The exhibitors were Messrs. G. Paul & Son, Mr. Keynes, Mr. Cant, and Mr. Turner. Instead, however, of particularising each stand by name, I shall just take out the names of the new Roses, first of 1867, and then of 1868. *Seniores priores*—so here are those of the former year: President Willermoz, Impératrice Charlotte, Reine du Midi, Clotilde Rolland, Madame Rolland, Reine du Portugal (Tea), La France, Enfant d'Ameugny, Christine Nilsson, Elie Morel, Ernest Boncenne, Duchesse d'Aoste, Baronne de Rothschild, Prince Humbert, Madame Luizet (Bourbon), Madame Grondier, Pitord, Lisette de Béranger, Madame Adèle Huzard, Charles Turner, Docteur Hurta, Madame Marie Cirodde, Vicomtesse de Vesins, Barillet-Deschamps, Madame Noman, Alice Dureau, and Souvenir de Caillat. Of Roses of 1868 there were exhibited Victor de Bihan, Duke of Edinburgh, Devienne Lamy, Nardy Frères, Adrienne Christophle, Dupuy Jamain, Charles Fontaine, Julie Touvais, Souvenir de Monsieur Poiteau, Alphonse Fontaine, and Marie Ducher (Tea). Of Roses not yet out, and therefore I suppose English seedlings, there were Caroline Hole, Charles Perry, Lord Napier, Seedling No. 2 in Mr. Turner's stand, and Viceroy of Egypt.

It will be hardly necessary for me to go through each and all of these. There are many which I verily believe we shall never see much of, and some which I am sure are the very best of this year were not there at all, being, as I shrewdly suspect, strongly attacked by the budding-knife. Thyra Hammerick, which is a lovely Rose, Marquise de Mortemart, Madame Creyton, and Reine Blanche, were not exhibited in these stands, but I believe they will be found in many a winning one in another year.

I have little to add to my former observations on the Roses of 1867 at the Crystal Palace, and should hardly be inclined to add to the list I have already given. As to the Roses of 1868, in addition to those mentioned in that report, I should be inclined to give a trial to Dupuy Jamain, a large and well-formed flower, to Charles Fontaine, a deep crimson flower, shaded with scarlet, and Victor de Bihan, brilliant carmine; while Duke of Edinburgh has established its claim to be considered one of the very best dark Roses that we have.

With regard to the Roses not yet sent out, Viceroy of Egypt is simply Général Jacqueminot over again, and if exhibited with that name would, I am sure, pass muster with the judges. Lord Napier is a richly-coloured Rose, and Charles Perry is a promising flower.

Of other Roses which I have seen, I do not think much of Minerve, Adrien de Montebello, or Perfection de Lyon. Should I have an opportunity of seeing any other, I shall not fail to notice them in the Journal. There is little doubt, I fancy, that we are gradually obtaining larger and finer Roses; and although many still hold their ground, yet, probably, we shall each year see some fresh one taking the place heretofore claimed by older favourites. How seldom Général Jacqueminot appears now! although three or four years it was in every stand; Senateur Vaisse has succumbed mainly to Madame Victor Verdier; La Reine is nowhere, and so it will be with many others. We think now they cannot be beaten, by-and-by we shall wonder that we ever thought so.—D., *Deal*.

HARDY CLIMBERS AND OTHER PLANTS FOR WALLS.

ALMOST every garden has its iron or wood trellis, pillars, arches, ornamental or rustic wood and ironwork, which in most instances it is desirable to cover with climbers. There are arcade fronts, arbours, bowers, stumps and trunks of old trees—some objects pretty in themselves, which it is considered in good taste to enrich with lively beauty, and other subjects objectionable, which when clothed with foliage and flowers become ornamental. Walls too high or too low, sunny or shaded, never look so well as when so adorned.

It is not always advisable to cover with climbing or other plants every surface suitable for their training and successful growth; and in the case of buildings it is not judicious to train plants over an architectural mansion—its principal parts, perhaps no part, ought to be planted against, for as a work of art it should be seen in all its details. Buildings which have many enrichments should not have these covered, though it may be advisable to clothe the intervening spaces with foliage; and in the case of brick buildings with stone dressings, the plants ought to be confined to the brick portion only, and they should only be taken up the height of the stonework, and not so as to cross it with the view of covering the upper part of the building. The plinth, too, if of stone, ought not to be hidden, but the stems of the plants made to cross it in the angles, or in the least objectionable manner. A well-designed, well-built mansion needs no plant ornamentation. There is such an objection to covering architectural buildings, that it ought not to be done without an architect's advice; but there are some buildings so mixed in character, and so inartistic, that it is desirable to cover them with foliage. Plain buildings, especially if low, may, as a rule, be clothed with plants, as these give an appearance of height, or prevent the want of elevation in the building from being so much noticed. Nothing, however, is so incongruous as to have tall and low-growing plants on the same surface. They must all attain one height, and be kept to that by pruning. I do not think they look well trained higher than the first-floor window-sills, or if there be a string course, they should be kept under it; but if they are taken higher then they should not stop until the cornice or projecting roof is reached, but of that they should be kept clear, the whole wall being covered equally to one height.

In garden architecture there are many surfaces suitable for the training of plants. Walls built for division, or for affording shelter, when unplanted are cold and wearying to the eye, but become cheering when covered with plants. Besides walls, there are buildings which present surfaces with different aspects suitable for plants, some admirably suited for a class of shrubs whose flowers are handsome and desirable for bouquets, &c., and which cannot be depended on from plants in the open ground. Even the low walls of greenhouses or other plant houses are rendered less cool and uninviting when clothed with either foliage or bloom. Nothing in my opinion is so

ugly as a bare wall; it offers nothing which can interest, and a badly-covered wall is not much better.

Another great defect is that of employing plants without paying any regard to the character of the building, for as buildings vary, so ought the subjects; for instance, a building constructed of light-coloured materials will be subdued or toned down by planting subjects with bright green foliage and red-coloured flowers, as Roses, or such evergreens as Escallonias, not seeking too great a contrast like that which would result from a close and heavy mantling of Pyracantha, or Ivy. Massive buildings should be covered with close-growing, heavy-foliaged evergreens, as Pyracantha, Ivy, Magnolia, &c., whilst a light and elegant structure should be clothed with plants like the Clematises and Honeysuckles, introducing a few evergreens for winter effect.

Some persons object to climbers and plants against buildings on account of their making the walls damp. How far that opinion may be correct I cannot say. I am aware that plants covering a wall will shade, and to a great extent deprive it of heat and air; it will be covered with moss sooner than one exposed to the sun's action, but that is because it is shaded, and not because the plants make it moist. I am of opinion that they would tend to make a wall dry rather than damp. The only way in which I think the walls are rendered damp, is by their not being cut off at or a little above the ground line from damp ascending from the soil, and with plants this dampness will be increased by placing soil close to the wall instead of the loose rubbish from the building. From the watering of the plants, too, there will be more dampness than if there were no plants. That, however, shows not that plants make walls damp, but injudicious building, for all buildings ought to have the ascent of damp from the ground cut off by a layer of asphalt as high, if not higher, than the ground level, and above that the border for the plants should not be raised. I have seen the ground outside taken above the line of the asphalt or cement, and the walls made wet in consequence for several feet up. If the ascent of damp from the ground be cut off, and the soil not taken above the point at which it is cut off, no one will have need to complain of climbers making walls damp.

A proper border must be made for the plants. It is useless to plant them against a wall, if for a considerable depth and distance there is nothing but rubble. It ought to be removed, and proper soil put in to the extent of at least a yard from the wall, and to the same depth, placing in the bottom about 6 inches of rubble for drainage, and then a layer of turf or the rougher parts of the compost. The latter must vary somewhat in its composition, but most climbers will succeed in two-fifths of turf cut about 3 inches thick from a pasture where the soil is a rich loam, neither heavy nor light; one-fifth short manure, as that from a Mushroom-bed, or the fresh droppings from a stable, as free of straw as possible; one-fifth leaf mould, and one-fifth sharp sand. The turf should be chopped up rather small, and all the materials well blended together. The border should be formed of this compost, using the materials fresh, without laying them in a heap to decay, but the upper part of the border should be of finer soil to the depth of about 6 inches. The compost just described, laid up for three months, would be suitable for the purpose, chopping it up and making it rather fine. It would not grow all climbers, for it would be too rich for some, and too open for others, and not properly constituted for a few; but it can be made lighter by adding sand, omitting some of the ingredients, and replacing with others of a suitable nature, as will be stated hereafter.

Not only should proper soil be provided for the plants to grow in, but it should be in quantity sufficient to support the plants to full size. The width and depth named, 3 feet, will, in most cases be sufficient, but there will be cases in which a greater quantity of soil must be supplied for the roots. For instance, if the soil is wholly unsuitable, it should be taken out twice the width, and replaced with fresh. In some positions the plants have to be planted under gravel walks; then the soil ought to be taken out, proper provision made for the roots, and when the plants are put in, the gravel can be returned. The same remarks apply to places which are grassed over, and due regard must be paid to furnishing the plants with proper soil, and the grass should not be placed close to the stem, but an opening must be left all round.

There are soils which will only need to be trenched, working in enriching material, such as dung or leaf mould; and where it is a good loam, it will be sufficient to trench it 2 feet deep, and mix it with manure, or add the kind of soil required by the plant. The better the provision made for planting, the more the plants will be likely to succeed, and the sooner will the object sought to be covered be hidden; indeed, no plant ought to be planted-out without making good provision for the roots, for it is important that the plants root well, and if they do that they will be sure to grow well. Even the commonest should have the soil loosened, and be planted in some good soil, and any additional care taken at planting will be amply repaid.

As respects the time of planting climbers and subjects of a similar description, as they are mostly grown in pots, planting may be performed at any season, but best when they are about to commence growth, or in March, or earlier, according to the season. It is best to plant them out before they have grown much, and still better if they have not grown at all. The roots should be spread out, the soil shaken from them without injuring the fibres, and a good watering given at planting, and afterwards in dry weather, so as to promote free growth.—G. Abbey.

(To be continued.)

FRUIT PROSPECTS IN YORKSHIRE.

Our fruit crop, in this neighbourhood at least, is anything but cheering. I thought at the time of blooming that nothing could be more promising; but it has been decreed otherwise, and we submit, though with a feeling of regret.

Apricots, Peaches, and Nectarines for the most part have fallen; Plums and Cherries are but a mere scattering; Pears have mostly fallen, and are still falling; Apples are very scarce indeed, and what is worse, many of the trees are suffering from caterpillars which are very numerous this season. The prevalence of blight and mildew does not augur well for another year. Filberts are very scarce; Figs and Walnuts are good; Gooseberries in some places are a fair crop, but sadly pestered with caterpillars. With us they are moderately abundant. Black Currants were very promising, but much of the best fruit has fallen. Red and White Currants were abundant, but what we call "honeyfall," came upon the trees. They had at first the appearance of being glazed over with gum; then came insects, then mildew, after which the leaves began to fall, and were followed by the fruit. What is left I fear will do little good. Raspberries up to the present time are very promising; Strawberries with us, as in many other places, are a failure. Some of the plants are suffering from mildew. Thus our fruit prospect for the present is only a gloomy one.—M. H., *Acklam Hall, Middlesbrough-on-Tees.*

THE GARDENS AT RED LODGE, NEAR SOUTHAMPTON,

THE RESIDENCE OF MRS. PEARCE.

Many very handsome villas have within the last twelve or sixteen years sprung up at the top of the rising ground above this splendid approach to Southampton, upon what was formerly only a waste densely covered with heath and furze. If a pleasing situation, giving great facilities for drainage, and the enjoyment of pure air, be considerations in choosing a residence, all these are secured here. Upon this plateau is the house of Mrs. Pearce. It stands apart, at the meeting of the roads, close to the Red Lodge Nursery of Mr. Rogers. A hedge divides her grounds from the nursery on the south, and the road to Shirley passes in front of her garden. There is often as much, if not more, landscape beauty in the scenery of the banks of a small river than in the vicinity of large rivers, of which the waters are frequently muddy and sluggish.

Although the garden is not large, it is kept in a very creditable condition, and there is a pleasing piece of lawn in front of the house about an acre in extent, whilst opposite the drawing-room windows is a small but well-filled flower garden. Adjoining the house is a small conservatory always kept gay. Leading west from the front is a gravel walk skirting the little paddock on one side; and on the other side there is a border planted with choice Rhododendrons and Roses, with some rows of mixed Tricolor Pelargoniums in front. Further on the walk crosses another walk, and here it is bordered with Rhododendrons, with standard Roses in front of them; and nearer the walk, at intervals of 3 or 4 yards, of strong plants of two common sorts of China Roses, with shoots from 3 to 4 feet long falling partially out on every side. These Roses and the various-coloured Snap-

dragons give a charming appearance, especially where backed up, as here, with Rhododendrons. To fill up the ground Mr. Kerr has a variety of the best annuals among the Roses.

The stove and Orchid houses, however, are the prominent attractions of this pleasing residence. I will here note a few of the plants I saw in the houses during a recent visit; and I may state that Mrs. Pearce feels a pleasure in allowing those interested to inspect her Orchids, of which no other such collection is anywhere in the neighbourhood of Southampton.

One small house is filled with Caladiums. These Caladiums at once show how highly they are valued here, and that Mr. Kerr understands their cultivation. I noticed the following:—C. Chantinii, a large plant, about 6 feet in diameter, some of its leaves being nearly 2 feet long by 18 inches wide; C. Wightii, of similar dimensions, only the leaves not so large; C. Brongnisarti, as large; C. bicolor splendens, 4 feet in diameter; C. marmoratum, with very dark green foliage mottled with lightish blotches; C. pœcile; C. argyrites, prettily mottled with white upon a green ground; C. Belleymei, very effective, almost white leaves with green veins and margin. There are several others, most of them very large plants.

The Orchid house is not very large, but filled with good plants in excellent condition, and many of them producing a remarkable display of bloom, both as regards the length of the spikes and the number of flowers upon each. I will here only note a few of them—viz., Lælia purpurata, two spikes, with nine flowers, large and fully developed; Saccolabium retusum, beautiful; Oncidium roseum, with six spikes full of flowers; Phalænopsis grandiflora, with two spikes 3 feet long, three times branched, and having twenty-four blooms—the same spikes flowered in the end of last summer; some Aërides in fine bloom; Miltonia spectabilis coming into flower, with fourteen spikes; of Cattleya lobata upwards of a dozen large plants; Brassavola Dighyana; handsome plants of Cattleya Mossiæ Pearcei, a very handsome variety; Brassia verrucosa with twelve spikes, occupying a low basket 3 feet square, the flowers with long spider-like segments, 8 or 9 inches across; Miltonia Moreliana, growing in a broad basket 2 feet 6 inches square, a fine plant with twelve spikes of dark bronzed-purple flowers; Oncidium Cavendishianum, throwing noble spikes; Cattleya Leopoldi with thirteen blooms; C. tigrina with fourteen blooms; and Oncidium leucochilum with three spikes 7 feet long, and upwards of a hundred flowers on each. There are twelve very large plants of different Oncidiums; pulvinatum having two spikes upwards of 6 feet long, and each spike more than three hundred blooms. Another plant had five spikes almost equal to those just mentioned. One had thirty side branches to the spike. Another plant had six spikes 2 feet 6 inches long. O. sphacelatum had eight spikes. One plant of Peristeria elata imported three years ago has two large bulbs like Spanish Onions, each bulb throwing up a very thick strong spike for flowering, now 3 feet long, but not yet offering to open its blooms. A young plant of Dendrobium giganteum had twenty-eight blooms, and Lælia superba had sixteen flowers on one spike. There were many others worthy of note, but the preceding will indicate the interest and care which is bestowed upon this class of plants by Mrs. Pearce.

I shall here note a few of the Ferns, and with these my notes will close for the present. In the Fern house are several Adiantums, always graceful when well grown. Some of them are very large specimens, and in very good health. Of Polystichum coriaceum capense there was a noble plant; of Gymnogramma Laucheana and G. Martensii, fine plants; G. Wettenhalliana, crested, silvery all over; Nephrodium molle corymbiferum, crested, intense green; Lomaria gibba, very healthy; Blechnum corcovadense; Platyloma flexuosum, fine large plant; and Thamnopteris nidus, with 4-feet fronds.—G. Dawson.

VARIATIONS OF CYTISUS AND PELARGONIUMS.

Loudon, in his "Hortus Britannicus," gives Cytisus Laburnum and C. alpinus, the gardeners' lists add to these the purple. When we were living near Leicester we had in our garden all these, the purple bearing its racemes of a brownish purple colour. A few days ago I received from a friend visiting at Springford Park, near Ripon, a branch of Laburnum bearing at the apex the fine yellow bloom of alpinus, and, growing on the stem below, erect purple racemes, while the yellow bloom was drooping. On other branches of the tree the flowers were much paler, almost lilac in colour. My friend was told that this change was produced by grafting, but this appears rather problematic. Roses are never known to fall back into the habit of their stock.

This singular capriciousness reminds me of a similar change in an Oak-leaved Pelargonium. I purchased one of these plants for the sake of past associations. I knew the old-fashioned Oak-leaved Pelargonium fifty years ago, so common in cottage windows in Staffordshire. We also cultivated it, admiring its finely formed flowers of a pink-violet colour with crimson lines; "coarse-growing," we used to say, but very effective. However, when my plant flowered the petals were of a rich crimson, quite unlike my early favourite, though very handsome. In process of time the plant became large and "leggy," and was turned out into the borders. In a few weeks its bloom changed. There were still heads of crimson, but others of the true old-fashioned colour, while some bore particoloured flowers, or the two tints side by side. I have a dried specimen which I have kept as a proof that, do what you will, the old nature still asserts itself. Will this at all explain the anomaly in the Laburnum?—Anna Harrison.

[In all probability the branch of Laburnum with various-coloured flowers was Cytisus Adami, which was originally produced upwards of forty years ago in budding Cytisus purpureus on the common Laburnum. In this process it is supposed that a cell of the one species became divided and united to a cell of the other, and the result has been a plant producing not only flowers of each species separately, but others partaking of the characters of both. There are other instances in the vegetable kingdom in which a similar union of cells is believed to have taken place, but Cytisus Adami is the best known and best established. Mr. Fish has added the following interesting notes on the subject:—"The changes produced on the Laburnum when grafted are sometimes wonderful and wholly unaccountable. We have rarely seen the common or Scotch Laburnum sport into other varieties. We recollect of only one instance in which flowers of purpurascens appeared. But if you graft either of the Laburnums with Cytisus purpureus or Cytisus supinus, the vagaries which sometimes take place are astonishing. I can see any day a small standard of Cytisus alpinus which was grafted with Cytisus purpureus, and on the same branch will sometimes be found small pieces of yellow and purple, and at the very point strong shoots of the Cytisus alpinus, the 'blood' of the stock finding its way through the more weakly growth of the scion. What is remarkable is, that grafting or budding with one variety will frequently, as the plant grows, present you with three or four varieties, or what are called 'species.'

"Such sports as you allude to in your Pelargonium are more common. From sports some fine varieties are produced. For instance, Rollisson's Unique Pelargonium is very fine when well grown. A lilac variety now becoming common was merely a sport from a single shoot that came on the rich crimson kind, and having been propagated maintains its distinct colour. We should be inclined to say that your plant would have exhibited similar features if you had not planted it out, though the fresh soil and freer growth might have had some effect in making the plant return to its more normal type.

"The coloured Lotus is the corniculatus ruber. There are two varieties of it—one with more fibrous roots, and one with roots somewhat tuberous. The latter stands the winter in the open ground the better. All coloured-foliaged plants have a tendency to revert to the original type."]

CULVER-KEYS.

A writer in "Notes and Queries" states that he has a note that the Oxlip is called "Cover-keys" in Kent. This is a mistake. In that county the Cowslip is often called "Lady's-keys," and only occasionally "Coney-keys." The latter, I believe, is a Sussex name rather than a Kentish one, and may have been given in consequence of rabbits being so fond of the flower spike of this plant. I may, however, add that in all places where I have heard the above name given, Cowslip was also understood as being one of the flower's names, even among the poorest and most illiterate.

The Oxlip, a sort of intermediate between the Primrose and Cowslip, is sometimes met with in Kent, but rarely, and not plentifully-enough to obtain a distinctive name amongst those who gather Cowslips by the bushel for May garlands and other purposes. Primroses of a dull colour are not uncommon in a

wild state, but are often the offspring of the outcasts of a garden.

Saxifraga granulata plena, a pretty double-flowering plant, is not so plentiful as it ought to be, and is liable to be lost when grown amongst other robust subjects. I find it is sometimes called the Mountain Ranunculus, a term not at all inappropriate.

How many names has the purple Meadow Orchis, Orchis latifolia? I have not taken much notice of such matters, but believe this has more names than the Cowslip.—J. Robson.

[The Oxlip or Cowslip could not have been the Culver-keys, because the flowers of this plant are described as blue. Thus John Davors, the angler and poet, quoted by Walton, delighted in walking "by fresh rivers"—

> "Among the Daisies and the Violets blue,
> Red Hyacinth and yellow Daffodil,
> Purple Narcissus, like the morning rays,
> Pale Gander Grass, and azure Culver-keyes."

For similar reasons Saxifraga granulata does not satisfy the description, its flowers being white. The flowers of the Orchis are in unison with that of Culver-keys, but we fail in any name for that Orchis, either English or foreign, that approaches that of Culver-keys. Its German name, Creutz blum, is the nearest, remote as it is. Our own opinion is that the wild Hyacinth, Scilla nutans, is the Culver-keys of John Davors. —Eds.]

PEWITS AS VERMIN KILLERS.

I should be much obliged by "I. N. P." stating how he manages his pewits—lapwing plovers I take them to be—through the winter? I also had some last year in my garden, and found them very useful. But although there was plenty of food and shelter for them in a large walled garden, they gradually pined away, and died in December. The last survivor, which I examined after death, seemed to be nothing but skin and bone. Is it necessary to feed them at all? and if so, what kind of food should be given? I tried small pieces of raw meat, but the birds would not touch it. I shall be obliged to "I. N. P." for some hints as to his own practice, and also if he would tell me where the birds are to be purchased.—H. E. W.

ROYAL HORTICULTURAL SOCIETY.

July 6th.

Fruit Committee.—George F. Wilson, Esq., F.R.S., in the chair. Mr. William Paul, Waltham Cross, exhibited a collection of thirteen varieties of seedling Strawberries, selected from a great number of other seedlings, which fruited for the first time last year. These were accompanied with details as to their parentage, which proved of much interest. Some of them were of considerable promise, yet none of them proved sufficiently rich to merit any special award. The present season, it may however be remarked, is so very unpropitious for Strawberries, that the best varieties are only of very indifferent quality. Mr. J. Trotman, Spring Grove Nursery, Isleworth, sent a seedling Strawberry of considerable promise, a hybrid between Black Prince and British Queen, showing very distinctly its parentage as regards both varieties. This was commended by the Committee, and Mr. Trotman was requested to send it again next season for farther testing.

Mr. Eckford, gardener to the Earl of Radnor, Coleshill, sent three bunches of a seedling white Grape, named Coleshill White Hamburgh. The bunch was large; berries large, slightly oval. It was, however, not quite ripe, so that no correct decision upon its merits could be arrived at.

Mr. J. Good, gardener to Lonisa Lady Ashburton, Melchet Court, Romsey, sent a very fine specimen of the fruit of Monstera delicious, Mr. J. Hepper, gardener to J. B. Walmsley, Esq., The Elms, Acton, exhibited six very fine specimens of Ripley Queen Pine Apple, averaging in weight from 4½ to 5 lbs. each, and all exceedingly well grown. A special certificate was awarded. Mr. T. Record, gardener to Col. Loyd, Lillesden, Hawkhurst, Kent, sent some ripe fruit of Tacsonia Van-Volxemi, which are edible in the same way as, and very much resemble in taste, &c., those of the Granadilla, or Passion Flower, and have a very agreeable perfume. The fruits are from 4 to 6 inches in length, from 1 to 1½ inch in diameter in the middle, and taper to both ends. When ripe they are of a pale greenish green colour, having altogether quite an ornamental appearance. "The fruit," Mr. Record stated, "hangs about nine months on the plant before ripening; but such extraordinary vigour does the plant possess, that it flowers profusely the whole time; if supplied with plenty of moisture, nearly every flower produces a fruit. Some of the fruit I send you has been cut several days." These fruits, unfortunately, did not arrive in time for the meeting of the Committee.

Messrs. Rivers & Son, nurserymen, Sawbridgeworth, exhibited twelve pretty examples of miniature Apple trees, about 2 feet in height, quite clustered with excellent fruit. These had been grown in the open ground in the ordinary way. They were grafted on the English Nonesuch Paradise stock, which was raised by Mr. Rivers from seed of the Nonesuch Apple, and which in the soil at Sawbridgeworth gives great fertility to trees grafted on it. These were more immediately exhibited, as stated by Mr. Rivers, to show their productive habit and fitness for suburban gardens, as they may be planted from 3 to 4 feet apart with advantage. A special certificate was awarded.

Messrs. Carter & Co., and Messrs. Hurst & Sons, seedsmen, exhibited examples of Laxton's Alpha Pea, a blue-wrinkled Marrow, as early as Sangster's No. 1. This is one of Mr. Laxton's numerous cross-breds, and a very excellent sort. The pods are larger and more curved than Sangster's. This variety has been grown and tested at Chiswick for two seasons in succession, and has there proved in all respects a decided acquisition. It was awarded a first-class certificate. Mr. Wm. Paul exhibited examples of Waltham Hardy White Cos Lettuce; and Mr. Perry, gardener to F. G. Debenham, Esq., Chesbunt Park, sent very good examples of a White Cos Lettuce, both of which were considered to be the ordinary form of White Cos Lettuce of the market gardens. Mr. Gilbert, gardener to the Marquis of Exeter, Burghley, Stamford, sent a very splendid collection of vegetables, which, however, arrived too late for the adjudication of the Committee. Some of the samples were very splendid, and called forth the admiration of everyone, in particular the Cauliflower. Mushrooms, Globe Artichokes, and Turnips. It consisted further of good dishes of Potatoes (four varieties), Carrots, Peas, Lettuces, Onions, and Cucumbers.

From the garden of the Society came ripe examples of the early Pears, Citron des Carmes and Amiré Joanett, which this season are rather later than usual, and very small.

Floral Committee.—Rev. J. Dix in the chair. The Messrs. Veitch, as usual, exhibited a very fine collection of plants. Among these Cypripedium Parishii was remarkably fine and distinct; a first-class certificate was awarded it. To Miltonia Regnelli purpurea, very beautiful, a first-class certificate was also given. A special certificate was awarded the collection.

Mr. Bull sent a large collection of plants, many of them too old for the special object of the Committee, or not in condition for adjudication. A special certificate was awarded the collection. Messrs. Downie, Laird, & Laing exhibited seedling hybrid Zonal Pelargoniums, promising, but seedling plants, which the Committee cannot recognise. Messrs. Rollisson sent a collection of plants, which was awarded a special certificate.

Mr. Appleby received a first-class certificate for seedling Lobelia Mauve Queen. In colour this Lobelia was considered as a desirable variety, and promising for decorative purposes. Mr. Noble sent a fine plant of Spiræa palmata, as beautiful and attractive as ever; indeed, one of the most desirable hardy plants in cultivation, one which no amateur should be without. Mr. Hally sent specimens of a double Zonal Pelargonium, Mrs. Hally, rose-coloured flowers, but not distinct from many others. Mr. Perry, gardener to F. G. Debenham, Esq., sent Fuchsia Mrs. Perry.

Messrs. E. G. Henderson exhibited a collection of dwarf seedling Lobelias, also a splendid selection of decorative plants in small boxes, which were awarded a special certificate. Messrs. E. G. Henderson were also awarded a special certificate for a collection of curious terrestrial Orchids, many of them of botanical interest. Among these were several Satyriums from the Cape.

From the gardens at Chiswick came a box of Aubrietia purpurea variegata; if constant in colour, it will be valuable. This was requested to be sent again.

Mr. Coppin sent a collection of seedling Roses, and Mr. Eckford, Coleshill, seedling Ivy-leaved Pelargonium, Lady Evelyn, which it was requested should be sent again.

From Mr. W. Paul came seedling Nosegay Pelargonium Cyrus, and a collection of cut Roses in fine condition, which received a special certificate. Mr. Brown, Sudbury, sent specimens of a pure white Gladiolus.

Mr. Williams, Holloway, had a pretty plant of Adiantum capillus-Veneris undulatum, which received a first-class certificate. Mr. Lorrimer, gardener to E. Salt, Esq., sent a fine specimen of Oncidium macranthum, which most deservedly received a special certificate. Mr. Hooper, Bath, exhibited a seedling Picotee, Princess Teck, too coarse; Mr. George, Putney, seedling Zonal Pelargoniums. One of fine form and truss, a hybrid Nosegay, called Harry George, received a first-class certificate. Mr. Cooper brought a collection of Cacti, which, though limited, was very interesting, and received a special certificate.

G. F. Wilson, Esq., a most enterprising exhibitor of Liliums, and to whom the Society is much indebted for his perseverance in bringing this interesting class of plants to notice, received a special certificate for a magnificent specimen of L. longiflorum, with an unusual number of flowers. We sincerely trust Mr. Wilson may be supported in his earnest endeavour to bring this class of flowers to public notice. Great confusion at present exists in the nomenclature, and any light which may be thrown on this now neglected family, will be most acceptable. Much may be done, and remains to be done, as to the dis-

tinction of these plants. It is most earnestly to be desired that this example may be followed. How much the horticultural world has lost by the neglect of this beautiful family, is now a subject of consideration, and we hope that support by way of information will be readily afforded. What is specially desirable is to arrive at specific names, and what are seedling or garden varieties. The Society, as well as the promoters of the cultivation of the Lilium family, will be glad of any information or assistance in bringing these noble flowers again into notice.

Mr. W. Paul received a special certificate for his collection of cut Roses; he also sent seedling Roses and Zonal Pelargoniums. Mr. Smith, Edmonton, sent seedling Zonal Pelargoniums.

Mr. Green, gardener to W. Wilson Saunders, Esq., sent a collection of very interesting plants; a species of Momodes, a very beautiful Orchid, which received a first-class certificate; Brassavola lineata, a very attractive Orchid—first-class certificate; and others. A first-class certificate was awarded the collection. We must notice from this garden came also specimens of a lovely climbing Rose, a single sweet-scented flower, most valuable as a decorative climber. This Rose is in the sole possession of Mr. Saunders, and was raised from seed introduced by the late Dr. Royle; also cut specimens of a hardy ornamental plant, almost unknown, Stuartia pentagyna, were furnished from this gentleman's garden. It is one of the most beautiful hardy shrubs ever seen, and should be sought for by all lovers of ornamental hardy shrubs. Every meeting seems to draw from this valuable collection of plants some hidden or, at present, unknown beauty. The Society may well be proud of so staunch and liberal a supporter of its objects.

Sir W. Parker exhibited a very fine specimen of a Clove Carnation, Souvenir de Malmaison; its gross flowers devoid of all symmetry, condemn it in the eyes of a florist; it is a plant in the esteem of all amateurs and florists devoid of any merit.

Interesting specimens of double and semi-double flowers of the Potentilla were sent from Chiswick Gardens; their merit as ornamental plants is of the highest order, and with careful attention they will prove most useful among decorative herbaceous plants. We have reason to believe that in a short time surprising varieties will be introduced.

Mr. Perkins, of Leamington, sent fine specimens of a seedling tree Picotee, a fine yellow good flower, which received a first-class certificate. Mr. Edwards sent Pteris serrulata cristata magnifica—first-class certificate, distinct from the tasselled form. Mr. Turner, Slough, sent seedling Roses—Caroline Hole, Lord Napier, a promising variety; Floreat Etona, Charles Perry, and Miss Poole, none of special importance. A special certificate was awarded to Mr. Turner for a box of his Rose Miss Ingram, a flower of much beauty. Mr. William Paul exhibited seedling Roses, and a special certificate was awarded for his superb collection of cut blooms. Mr. W. Paul also exhibited Zonal Pelargoniums, among them Waltham Bride, a dwarf Silver Bicolor, which will be most useful; this had received a first-class certificate on a previous occasion. His collection of cut flowers of Zonal Pelargoniums was much admired. Mr. Laxton sent four seedling Roses, but not in condition, or in any way equal to many known varieties.

Major R. Trevor Clarke exhibited a seedling variegated Ilex, but not considered permanently fixed; also a Mammillaria, a fine specimen, which he has kindly offered to the collection of these curious and interesting plants at Kew.

Messrs. Barr & Sugden sent a fine collection of Spanish and English Iris. Of the beauty of this class of plants too much cannot be said; they are of little reputation among amateurs, but are of great value, easy of cultivation, and most ornamental. Years ago one of the oldest Fellows of the Society, whose name is well known, and whose labours in horticulture will for ever be respected, Mr. Masters, of Canterbury, paid much attention to this family, and possessed a very unique and fine collection, but from want of appreciation till the present time they seem to have been lost. We cannot too strongly recommend attention to these flowers. Useful for decoration and beautiful in themselves, no garden should be without a well-assorted collection of them.

The meeting this day was most successful; and we would here venture to hint that much labour would be spared the Committee if only novelties were entered for their consideration.

Prizes were awarded for twenty-four Carnations, which, like the Picotees, were of first-class character. Mr. Turner was first for twenty-four with Premier, Defiance, Col. Windham, Dreadnought, Juno, Sensation, Prince Albert, James Merryweather, Splendour, Beauty of Woodhouse, Lady of the Lake, William Cowper, Favourite, Princess Royal, Companion, John Reet, Eccentric Jack, Christopher Sly, Merrimac, Africana, Dr. Foster, Rifleman, True Blue, and Rainbow. Mr. Hooper, Bath, was second, and Mr. Bragg, Slough, third. For twelve Carnations Mr. Norman, a veteran grower, whose name is most welcome again, was first with Lady of the Lake, Robinson's John Reet, Seedling, Miss Napier, Baildon's Juno, Juba, Mayor of Nottingham, Simpson's Queen, Ward's Sarah Payne, Kay's Comet, and Delicata. Mr. Smith, Bath, was second; Mr. Kingston, Bath, third. For six Carnations Mr. Norman was first with Julia, Juno, Comet, Mayor of Nottingham, John Reet, and Lady of the Lake. Mr. Kingston was second; and Mr. Smith, Bath, third.

For twenty-four Picotees, Mr. Turner was first with Lucy, Prince Arthur, Exquisite, Miss Wood, Pecco, Emmeline, Lord Nelson, Ascot Giant, Amazon, Mrs. Hobbs, Mrs. May, Finis, Alfred Ingleton, Mrs. Dodwell, Miss Williams, Countess, Rosetta, Northern Star, New Colour, Duke of Devonshire, and two or three seedlings. Mr. Hooper was second, and Mr. Pilgrim third. For twelve, Mr. Kingston was first with Polly Perkins, Miss Matthews, Lady Peel, Antonia, Mr. Varley, Lady Grantham, General Pym, and Jessie. Mr. Smith was second. For six Picotees, Mr. Norman was first with Mrs. May, Miss Wood, Eliza Payne, Miss Sewell, Princess of Wales, and a seedling. Mr. Kingston was second. For thirty-six Carnations, Picotees, and Cloves mixed, Mr. Turner was first, Mr. Hooper second; and for twelve, Mr. Kingston was first, Mr. Smith second, and Mr. Norman third.

The collections of these flowers were of first-rate character, and the blooms exhibited quite sufficient to again make them great favourites with all who admire these essentially beautiful flowers.

General Meeting.—W. Wilson Saunders, Esq., F.R.S., in the chair. Six new Fellows having been elected, and the Committee awards announced, Major Trevor Clarke, in the absence of the Rev. M. J. Berkeley, through illness, directed attention to some of the plants exhibited. He particularly noticed Pelargonium Empress, which, instead of having flat rounded petals, like a florist's flower, exhibited beautiful undulating lines; the Satyriums from Messrs. Henderson, a class of Cape ground Orchids well worthy of notice, and of which Sir John Herschel is one of the greatest cultivators; the Carnations and Picotees, of which he remarked that there is yet very much to be done in crossing and hybridising with each other and the various forms of Dianthus; and Spiræa palmata, than which he considered a more beautiful shrubbery plant could scarcely be conceived. Stuartia pentagyna, closely allied to the Cotton plant, was then pointed out, and slices of the Giant Puffball, Lycoperdon giganteum, of which large specimens were sent by Messrs. Carter & Co., were handed round, Mr. Saunders assuring those present that it might be eaten with perfect safety.

Major Clarke, on again proceeding, referred to the white Lily from Mr. G. F. Wilson, as being probably merely a well-grown plant of Lilium longiflorum, and produced a Lily raised from the seed of the common Martagon, which he supposed had been fertilised with the pollen of the common white garden Lily; likewise Sweet Peas, showing the result of crossing the common purple with the Scarlet Invincible for three generations, and the more it was crossed the darker it became. Aspernla azurea was noticed as a pretty plant for a mass, pincushion bed, or edging.

Mr. Wilson Saunders next directed attention to the fruit of Monstera deliciosa, which he said he had used three or four times with great pleasure. It should be used just before it became over-ripe, and was then extremely luscious and delightful; it was, however, not pleasant when eaten before it arrived at that state, nor afterwards. It should be taken just when the outer scales begin to fall off, and has then somewhat of a Pine-Apple flavour united to that of spice. With regard to the Briar Rose, noticed in the Floral Committee report, it was introduced by Dr. Royle from the Himalayas; it would spread over an immense space, its flowers were sweet in the extreme, but though so luxuriant, it would not bear cutting. It had been very troublesome to propagate till last year, when it was found to strike very readily from cuttings of the quite young wood.

Mr. Bateman, after brief reference to the Monstera and the spiculæ which render it objectionable when it is not eaten at the proper stage of ripeness, mentioned that an enormous Arum had been discovered in Nicaragua, and pointed out some of the most remarkable of the Orchids, especially Cypripedium Parishii and Thunia Bensoniæ, remarking, in connection with the latter, that he hoped Colonel Benson, at present in this country, would come to the next meeting, and give his experience relative to this and the other fine Orchids which bear his name. The new species of Mormodes from Mr. Wilson Saunders, showed how Mormodes and Cycnoches run into one another The beautiful specimen of Oncidium macranthum from Mr. Salt's gardener was described as being particularly worthy of notice, and Mr. Bateman said that the sooner the absurd adjunct of hastiferum was cut off the better; for the plant exactly answers to the description of O. macranthum which Messrs. Veitch had introduced many years ago, but which had been lost from not receiving the proper treatment; the temperature required was that of an ordinary greenhouse. With regard to the ground Orchids of the Cape, he hoped they were the first fruits of a large harvest from the same source. As an instance of their beauty he quoted Herschelia cœlestis, of which the blue of the flowers calls to mind the tint of the southern sky. The Satyriums were only another instance that as fast as certain branches of horticulture seem to become exhausted others come forward to take their place.

Mr. Bateman then gave an entertaining lecturet on the Coco de Mer, or Double Cocoa Nut of the Seychelles Islands, illustrated by specimens from Kew and the South Kensington Museum. He gave extracts from Rumphius, showing what were the superstitions of the natives of the Spice Islands concerning it, the value of the nuts, and the singular medicinal virtues ascribed to them; that the tree was believed to grow at the bottom of the sea till at last it was discovered that it grows in the Seychelles, and that its fruits, falling into the ocean, are carried hundreds of miles away. The uses made of the

nut, and of the leaves for ornament and thatching, were alluded to; likewise the labours of Von Martius in connection with Palms; and Mr. Bateman detailed the circumstances of his first introduction to him, and concluded by expressing a wish that all English botanists and horticulturists would be as kind to foreigners as the latter invariably are to the English.

At the conclusion of the meeting, specimens of the pretty Lithospermum petræum, from Mr. W. Robinson, were exhibited, after which the Chairman announced that the next General Meeting would be held at Manchester, on the 20th inst., and the following one at South Kensington, on August 3rd.

ENTOMOLOGICAL SOCIETY'S MEETING.

The June meeting of the Society was held at Burlington House, the President, Mr. H. W. Bates, being in the chair. Among the donations to the Society's library received since the last meeting were the publications of the Royal and Zoological Societies, and the Natural and Entomological Societies of St. Petersburgh, Berlin, Vienna, Geneva, Leyden, &c. A new part of the Society's "Transactions" containing a portion of Dr. Sharp's monograph on the genus Homalota, and the fourth part of Mr. Hewitson's splendid work on the Butterflies of the family Lycænidæ, were also on the table.

Mr. Pascoe exhibited a small but very remarkable Coleopterous insect, captured by Mr. Du Boulay at Champion Bay, New Holland, which seemed to be allied to the Histeridæ and Clavigeridæ. (It has since received the name of Chlamydopsis striatellus, *West.*) Mr. Stainton exhibited specimens of a curious new species of Tineina, with large bushy polypi, reared by M. Milliere, of Cannes, from Osiris alba, and named by him Paradoxus Osiridellus. Mr. F. Smith exhibited a living specimen of Physonota gigantea, a Beetle of remarkable metallic beauty during life, but whose colours fade soon after death. It was found in considerable numbers in a cargo of logwood from South America, at Liverpool. Likewise a living specimen of the larva of a Beetle of the genus Pyrophorus (?), which emitted a brilliant green light from the ten spiracles along each side of the body, whilst the head gave forth a bright red light, the intensity of the colours causing Mr. Smith to compare them to the red and green signal lamps of a railway train. It had been communicated to the British Museum by Mr. Lettsom from Maldonado, and had remained alive for two or three months in damp earth without food.

Mr. Stainton exhibited specimens of Gelechia atrella, the larva of which resides at first in a moveable case, formed by cutting off and flattening a small portion of the stem of an herbaceous plant, and afterwards burrows down the stem of Hypericum.

A letter was read from the Secretary of the Flax Improvement Society of Belfast, relative to the injury done to the Flax whilst in the seed leaf by a small Beetle, Thyamis parvula, *Paykull*, nearly allied to the common Turnip Flea Beetle.

Professor Westwood exhibited specimens and drawings and read descriptions of several remarkable small Coleopterous insects, chiefly from Western Australia, several of which had been collected by Mr. F. Du Boulay at Swan River and Champion Bay, illustrating the affinities of the anomalous genus Ectrephes, *Pascoe* (Anapestus, *King*), with the Ptinidæ.

Mr. Druce exhibited a collection of Butterflies from Borneo, including a fine new Ornithoptera, and other new species.

Mr. F. Smith exhibited a parasitic British Bee, Melecta armata, which was infested to so great an extent with the minute larvæ of Meloe, that it was unable to fly, and was found struggling in the grass. He also read a memoir containing "Descriptions of new species of the Hymenopterous genus Pison, and a synonymic list of those previously described." The species are nest-builders, the nests resembling those of the genus Pemphredon, and being provisioned with spiders. The number of species has been raised by Mr. Smith to forty-three, the majority being natives of New South Wales. He also read descriptions of some other new genera and species of exotic Hymenoptera, including a Methœa from North China. Mr. Charles Horne communicated a report made to the Indian Government upon the ravages of the Carpenter Beetle in all parts of India.

Mr. F. Walker read a note on the habits of certain Chalcididæ, which appear to be herbivorous instead of parasitic, and on a new species of Megastigmus.

Major F. Parry read "Observations on Lucanoid Coleoptera, with Remarks on some New Species, and on the Present Nomenclature, accompanied by a Revised Catalogue of the Species;" and Mr. A. R. Wallace read "Notes on Eastern Butterflies (continuation—Erycinidæ and Libytheidæ), with Descriptions of various New Species belonging to these Families collected by himself in the Malayan Archipelago."

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

Dendrobium densiflorum var. albo-lutea (White and yellow Dense-flowered Dendrobe). *Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria.—Native of the Moulmein forests.—(*Bot. Mag., t.* 5780.)

Vaccinium reflexum (Reflexed-leaved Whortleberry). *Nat.*

ord., Vaccinaceæ. *Linn.*, Decaudria Monogynia.—"A beautiful little Andean rock plant, conspicuous for its pendulous habit, the deep glossy green hue of the leaves, which are reflexed on the stem and branches, the bright pale red hue of the young foliage, and deep red flowers. It was introduced by Messrs. Veitch, through their late energetic collector, Mr. Pearce, from Bolivia, and flowered in their establishment in the King's Road, Chelsea, in January of the present year."—(*Ibid.*, *t.* 5781.)

Geonoma Ghiesbrechtiana (Ghiesbrecht's Geonoma). *Nat. ord.*, Palmaceæ. *Linn.*, Monœcia Hexandria.—A very ornamental Mexican Palm. No stem; leaves from 2 to 5 feet long.—(*Ibid.*, *t.* 5782.)

Dipladenia Boliviensis (Bolivian Dipladenia). *Nat. ord.*, Apocynaceæ. *Linn.*, Pentandria Digynia.—Native of Bolivia; the other species have hitherto been found on the east coast of South America only. It is very beautiful, flowers white with yellow tubes. Introduced by Messrs. Veitch.—(*Ibid.*, *t.* 5783).

Pterodiscus luridus (Lurid-flowered Pterodiscus). *Nat. ord.*, Pedalinaceæ. *Linn.*, Didynamia Angiospermia.—"One of the most remarkable botanical features of the drier districts of South Africa, is the presence of plants of various natural families possessing short stout tuberous stems or caudices, rising a few inches above the ground, and sending forth from their crowns, on the approach of the wet season, a few stout herbaceous, succulent, leafy, flowering branches. They flourish best in a moderately warm house, planted in a poor soil, amongst stones, &c., and exposed to the full light of the sun. The present example of this form of vegetation is a native of the Albany district of Cape Colony, and was sent to the Royal Gardens from those of Graham's Town, along with many other interesting plants."—(*Ibid.*, *t.* 5784.)

Moræa bulbifera (Bulbous Moræa). *Nat. ord.*, Iridaceæ. *Linn.*, Triandria Monogynia.—"The present species is one of the most beautiful of the genus, and produces a great multitude of its golden flowers in succession, which expand fully in the sunshine, and ornament a house for a period of several weeks. It is a native of various districts of South Africa, and was lately imported by our friend Mr. Wilson Saunders, F.R.S., through his indefatigable collector, Mr. Cooper. It was originally introduced into the Vienna Gardens so long ago as last century."—(*Ibid.*, *t.* 5785.)

Fig Col di Signora Blanca Panachée.—"To all lovers of beautiful fruits this, the most beautiful of all Figs, will be especially welcome. Nothing can exceed the charming appearance of a handsomely grown pot-tree of this variety, laden with its strikingly handsome Figs. The fruits are streaked (panachée), some more irregular in the markings, some almost yellow, and some reverting to the natural green; all, however, are very beautiful, and show their markings plainly, from the first appearances of the little embryo Figs, until their maturation. This is not a new Fig, but a sport from the better known Col di Signora Blanca, one of the finest Italian varieties, which it closely resembles in form and quality, and, like it, requires to be grown in considerable heat, so as to bring out fully the superior richness of flavour. It succeeds best grown in pots, under which conditions it fruits freely, and proves in every respect satisfactory. Fruit medium-sized, roundish-turbinate, evenly and regularly formed. Neck shorter than in the original. Skin thick, green, beautifully striped with longitudinal bands of bright yellow. Eye small, closed. Stalk short. Flesh deep rose, thick and syrupy, rich, and most delicious. The length and form of the neck of the first fruits are suggestive of the name, Lady's Neck."—(*Florist and Pomologist*, 3rd s., ii., 145.)

NEW BOOK.

A Practical Treatise on the Cultivation of the Grape Vine. By William Thomson, Gardener to the Duke of Buccleuch, Dalkeith Park. Sixth Edition, enlarged. W. Blackwood and Sons.

Six editions in seven years is evidence that the gardening community assent to our estimate expressed on the appearance of the first edition, that a book on Vine culture from Mr. Thomson's pen "must be expected to be excellent, and that the volume before us will not disappoint that expectation." There is much added to the present edition, and among the additions is this on "Vine Roots."

"The roots of Vines, like those of most other trees, have a tendency to descend into the earth, and when they reach certain subsoils they become unhealthy, besides which they are then far from the genial influences of sun and air. To prevent this, remove a few inches of the surface of the border every summer during dry weather, which will most probably expose some of the roots, at any rate descend till they are reached, then on, under, and amongst these young roots lay a few inches of nice fresh loam, horse droppings, and old lime rubbish in equal parts, with a few handfuls of ground bones. Into this mixture the Vines will send a mass of fine feeding fibry roots, that with similar annual attention may be kept there, where they should be mulched as already directed, and during very hot dry weather fed with liquid manure, either from the farmyard or cesspool. When neither of these is available, mix guano at the rate of 1 oz. to the gallon of water. If this process is persevered in, it reduces the importance of concreting the bottoms of Vine borders, as the Vines seldom suffer from any roots formed at too great a depth. An amateur close to this place has for many years grown splendid crops of Grapes, chiefly Muscats. The Vines are planted in an outside border, only 6 feet of which was made soil, and the roots are all right through it into the general soil of his garden, which is poor, shallow, and gravelly; but he annually covers more than 30 feet in width of the soil on each side of his span-roofed house with 6 inches of nearly solid cow manure, which during the year washes into the soil, and is, when examined, a complete mass of fine Vine roots, and is not disturbed except by the hoe, to kill weeds, the sharp hungry soil preventing all danger from over-feeding by such means. To this mulching, and occasional waterings during the late scorching summer of 1868, when every tree and bush, as well as weed, in his garden was covered with red spider, he attributes the immunity from that pest which Vines enjoyed. From this vinery I conceive a sound lesson in Grape-growing may be learned, hence my reason for referring to it."

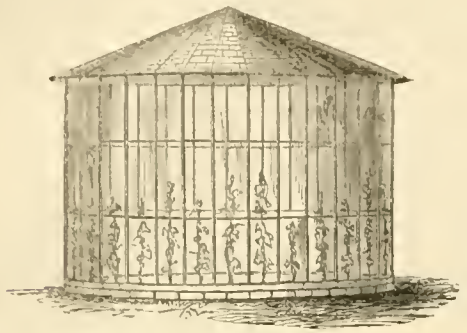
On the last two pages of the work Mr. Thomson gives an extract from a volume published in 1631, in which the first description of a vinery to be erected in England occurs. We restrict our sentence to England, because there is reason to believe from Martial's Epigrams, that the Romans had vineries as well as peacheries, and it is certain that they forced Cucumbers.

In 1614, Barnsby Googe published a translation of Heresbach's "Whole Art of Husbandry." In that, although directions are given for Vine culture, there is no allusion to a vinery. In 1631, another edition of the work appeared, edited by Gervase Markham, in which he does describe a vinery, adding —"This experiment hath beene approved in England and found most excellent." That edition we have not seen, but Markham in another volume he published in 1635, entitled "The English Husbandman," again describes the vinery as follows:—

"If you desire to have Grapes in their true and best kinde, most early and longest lasting, you shall in the most convenient part of your garden, which is ever the center or middle point thereof, build a round house, in the fashion of a round dovecoate, but many degrees lower, the ground worke whereof shalbe above the ground two or three brickes thicknesse, upon this ground-plot you shall place a groundsell, and thereon, fine, yet strong studs, which may reach to the roofe: these studs shalbe placed better then foure foote one from another, with little square bars of wood, such as you use in glasse windowes, two betwixt every two studs, the roofe you may make in what proportion you will, for this house may serve for a delicate banquetting house, and you may either cover it with leade, slate or tile, which you please. Now, from the ground to the top, betweene the studs, you shall glase it, with very strong glasse, made in an exceeding large square pane, well leaded and cimented. This house thus made, you shall observe, that through the bricke worke there be made, betweene every two studs, square holes, cleane through into the house; then on the outside, opposite against those holes, you shall plant the roote of your Vine, having beene very carefull in the election and choice thereof: which done, as your Vine groweth, you shall draw it through those holes, and as you use to plash a Vine against a wall, so you shall plash this against the glasse window, on the inside, and so soone as it shall beginne to beare Grapes, you shall be sure to turne every bunch, so that it may lye close to the glasse, that the reflection of the sunne heating the glasse, that heat may hasten on the ripening, and increase the groath of your Grapes: as also the house defending off all

manner of ovill weather, these Grapes will hang ripe, unrotted or withered, even till Christmasse."

Now, we have a copy of this volume, and some previous possessor has drawn on the page opposite the description, this illustration of the vinery :—



POMOLOGICAL GLEANINGS.

Citron des Carmes Pear.—Notwithstanding the extreme lateness of the season, the Strawberry crop being quite a fortnight later than usual, this Pear is now (July 5th) ripe, and falling from some old trees in quantities. The fruits are much smaller than usual, have a very scrubby appearance, and are not at all good-flavoured, or of their usual character. The finest fruits on the trees, and the whole crop on young plants, will yet require ten days or a fortnight to ripen. Last year the best fruits of Citron des Carmes were ripe on the 1st of the month, at the same time as Doyenné d'Eté, which this season will require quite a fortnight to ripen.

MULBERRY CULTURE.

When I first came to Welbeck in 1837, I was much struck with some large flower pots perched on the tops of two standard Mulberry trees, and imagined they were placed there for some species of birds to build their nests in. On asking the late Mr. Mearns, who was my predecessor as gardener there, he informed me that the late Andrew Knight, of Downton Castle, always used to raise his fruiting trees of Mulberries in that way. Mr. Mearns likewise informed me that Mr. Knight found out that, by propagating the Mulberry in the usual way, it required from twenty to thirty years' growth before it would fruit abundantly even in the south of England. I paid particular attention to these little Mulberry bushes, and, when perfectly rooted, had two of them in a fruiting state for many years, by shifting them, and growing them in large tubs. Mr. Mearns's trees were propagated by layering a small fruiting branch into the pot, and the pot afterwards fastened with strong wire to a branch or stake to keep the wind from shaking it. I believe the best way to produce a large fruiting bush of the Mulberry would be to have a large flower pot made into two halves, and when the branch was put in at the hole in the bottom of the pot, the pot could then be bound together and fastened to a strong stake; the pot would then have to be filled with earth of a strong loamy nature, and some fresh moss placed on the top and pegged down to keep the wind from blowing it off. This moss would keep the soil moist, for watering would be required in the summer months in dry weather.

In the midland counties in England it is only in exceptionally warm summers, such as 1846, 1865, and 1868, that standard Mulberries produce fruit ripe enough to use. The two standard trees from which the pot bushes were raised were planted by the celebrated Speechley, and must have been about 110 years old when I first knew them. Another tree of the same age was denuded of all its branches by Mr. Mearns, except two at the top, and planted on a high south wall. He began training all the young branches downwards from the two leaders, and they soon got into a fruitful state, and produced fine fruit. No doubt a sunken pit where Asparagus was forced in helped this tree's growth, for its roots came close to the wall where the hot dung-linings were put in. In 1858, when the new gardens were made, I had this tree lifted with a machine, and planted in nearly a similar aspect, but without the advantage of its roots being heated in spring. Every year since it has never failed in bearing fine fruit, but in the past summer they were larger and finer than I ever remember to have seen Mulberry fruit even in the south of England. The tree covers a large space, and was worthy of being covered with Nottingham netting, which I had to do to save the fruit from birds, wasps, and flies.—William Tillery (*The Gardener.*)

NOTES AND GLEANINGS.

Messrs. Barr & Sugden sent us "a specimen of the giant form of the White Cos Lettuce," and well it deserved the name. It was 15 inches high from the base of the leaves to the tip, and weighed more than 3 lbs. 7 ozs. Messrs. Barr and Sugden are carrying on some trials testing the merits of various Lettuces and Peas, the results of which we hope to publish.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Take advantage of dry weather to eradicate the weeds which have sprung up lately, and when the soil is not sufficiently dry for hoeing, handweeding should be resorted to. As the production of strong *Asparagus* next spring will depend mainly on the culture in the present summer, let the beds, after cleaning, be mulched with short grass or half-rotten manure. Liquid manure in which some salt has been dissolved should then be applied freely for the next month or six weeks, or the salt may be spread over the beds, to be washed in by the rains and watering. *Globe Artichokes* and *Sea-kale* will be improved by similar treatment. Continue planting out Cape and other *Broccoli*, also some late *Cauliflowers*. Water freely Cauliflowers, *Lettuces*, *Radishes*, and other vegetables which require to be grown quickly to have them crisp and tender. We need scarcely add that in all cases vegetables will be improved in size by giving manure water if it can be procured in sufficient quantities for all purposes. Continue planting out *Celery* as required, and the early crop may have a slight earthing, having previously taken off any lateral buds and well watered the rows. It is advisable to sprinkle a little salt along the Celery trenches before earthing them up, as it both kills slugs and worms and accelerates the growth of the plants. Keep up succession beds of Horn *Carrots*. Sow a good supply of early *Cabbages* or Chappell's Colewort for autumn and winter use. An autumn *Mushroom* bed may now be made. Throw the dung together to ferment for a few days; when half dry mix one-third of loamy soil with it to keep in check any further fermentation, and tread or beat hard while making the bed, forming the spawn-holes immediately it is finished, to assist in keeping down the heat. A crop of Parsley to stand over the winter should now be sown in a dry sheltered spot. Let a good breadth of ground be prepared for *Winter Spinach*; trench it thoroughly, and let it be heavily manured. This crop generally succeeds in beds slightly raised.

FRUIT GARDEN.

The nailing and tying-in of this year's wood should be continued. Many fine trees are in a bad condition from the uncongenial weather. Most kinds of fruit now ripe or ripening will require the protection of nets to preserve them from birds, which in most country places are troublesome neighbours, otherwise a boy must be employed to keep them from the small fruit during the fruit season. As the early Cherries are gathered, shift the netting to other kinds which are yet to ripen. Vines against walls should be closely nailed up, to obtain the benefit of what little heat there is in this unseasonable weather. Figs must be treated in the same way, pinching out the point of this year's wood, except the leaders, when they have made five or six joints. The breastwood may now be removed from Pears and Plums against walls, cutting away that on the upper part of the tree first, then after an interval of two or three weeks another portion, and finally finishing by a third cutting of the lower part. By this plan there will be less danger of the cut-back shoots starting again; and the lower shoots, which are generally the weakest, will gain additional strength by being allowed a few weeks longer to grow. Strawberry runners should be procured for new plantations without delay. Those who cannot spare ground for a new bed may prick them out in prepared beds about 6 inches apart, and remove them with balls in October or in the early part of February.

FLOWER GARDEN.

The recently planted beds will still require watching to get the plants in them fairly started. The heavy rains have chilled

the ground, and some of the more tender or badly rooted plants look sickly. As the grounds and shrubberies are much more frequented by company att his season, pay attention to preserving the greatest neatness and order in every part. Where there are enough hands to admit of it, flowering shrubs as they go out of bloom should have the dead flowers and leaves removed and be slightly cut back. For the same reasons remove the seed pods of Rhododendrons and Tree Peonies. These little attentions will be followed by an increased growth of the plants, and a greater certainty of their blooming every season. See that Hollyhocks, Dahlias, and the taller-growing herbaceous plants are properly secured to stakes. When growing, cut back the perpetual-blooming Roses as they go out of flower, and supply them with the richest manure water, to encourage a second growth and bloom. Strong shoots of Chrysanthemums may now be layered in pots to produce dwarf, compact plants. Carnations and Picotees will now be in bloom. Let plants in pots be moved under an awning. Here they may be arranged on a raised platform, or not, according to taste. Picotees may be grouped on one side and Carnations on the other, taking care that the tallest plants are at the back, at the same time contrasting the colours as much as possible. Pipings may be put in on a gentle bottom heat. Layering may also now or very soon be proceeded with, as much of next year's success depends on this. All seedlings should be marked, noticing their various properties of form, colour, and substance.

GREENHOUSE AND CONSERVATORY.

The conservatory should now be kept as gay as circumstances will permit. It is not desirable, however, to crowd it with flowering plants; the aim should rather be to have a moderate number of handsome specimens effectively arranged, which will yield more interest and pleasure than a greater amount of floral display from plants of no individual merit. We would recommend a thin arrangement of the pot plants, on account of the permanent occupants of the beds and borders, which at this season should be allowed plenty of space, in order to secure strong and well-ripened wood, without which they cannot be expected to bloom freely. Use every means to keep down insects, and let order and neatness be strictly observed. Hardwooded plants, including most of the genera from New Holland, which bloom early in spring, and which, after blooming, received the necessary pruning, will now be so far advanced in their new growth, that any requiring to be repotted should at once have a shift. After turning them out, loosen the outside roots before placing them in their new pots, to enable them to take to the fresh soil the more readily. Keep them close for a few days, especially if the roots have been much disturbed, and damp them once or twice daily overhead; water carefully at first, taking pains to insure the old ball having its proper share until the roots are established in the new soil. Attention at this season should be directed to the stock of plants intended to furnish the supply of bloom through the next winter, as it is requisite plants should complete their growth early for this purpose. Among Heaths, those which flower through the winter should also be encouraged to complete their growth, as they are great favourites in most places, a considerable number of such kinds as E. hyemalis, Willmoreana, gracilis, vernix, regerminans, &c., should be grown. Keep Epacrises under glass till their growth is complete; but more air and light should be allowed them, increasing it as the wood gets firmer. Towards the end of the month they may be placed out of doors in an open situation, but where they can be protected from heavy rains.

STOVE.

Stove plants which are intended for the decoration of the conservatory in autumn should now be carefully looked over, moving such as are likely to want more pot room, with a view of having the pots well filled with roots before the plants are required to flower; keep also the shoots tied out rather thinly, and expose the plants to as much sunshine as they will bear without scorching their foliage, in order to keep them low and bushy. Give clean weak manure water to young growing specimens, and repot any that are intended to have another shift this season.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Size of Gardens.—We are thus far gratified by the attention excited by what has lately been stated about the sizes of gardens, and the impossible returns expected from small ones. We know some very comfortable places where the kitchen garden is far too small to supply the establishment, but all concerned are satisfied, simply because Potatoes, Carrots, Turnips, and even most of the Cabbages are, with the exception of a few early ones, grown in the open field. Many of our roots are thus obtained sweeter and better, though not larger, than in an old kitchen garden. We hear of a number of other cases where the proprietors say, "We must not expect impossibilities, get what you can, and then we will purchase what you cannot produce for us." In the last ten years we could remember at least twenty cases in which clever, superior gardeners, left employers whom they would gladly have served, merely because they saw plainly that with the ground allotted to them they would every year be less able to meet the wants of an increasing establishment; and because, though the matter was more than hinted at, no remedy was forthcoming. They thought it more prudent to leave when all was going smoothly, than be obliged to leave after any unpleasantness about shortness of supplies. Some employers, like these, have expressed their wonder that a gardener should have left them—"Liked him much; never had a cross word with him; never, in fact, had occasion; offered him more money; would have done anything in reason; were perfectly satisfied, but could not make the garden ground larger." That was just the reason; an acre or even half an acre of ground would have made all the difference, were it only surrounded by a wire netting fence in the corner of a field.

It is pleasant to know that the heads of an establishment are satisfied; but the prudent man knows that repeated complaints of short supply at the tables of the establishment may in time turn the satisfactiou of an employer almost to dissatisfaction. A good display in the dining-room is all very well, but that will not atone for scarcity and lack of variety at the other tables in the house. After some experience we have come to the conclusion, that for a gardener to be comfortable and respectable in his position, he must have the means of giving a varied supply according to the season, not only to the dining-room, but to the other eating-rooms, be it steward's room, nursery, or hall—to glut, as it were, at least to give plenty to the head of the kitchen; and if that cannot be, then to have it fully recognised that you merely produce what your ground will give, and if more is wanted, the market must be resorted to, especially for early vegetables. It is no drawback to a gardener's reputation that Potatoes appear in the markets from Cornwall and farther south before his out of doors are half grown. We can only grow them better for the parlour by glass and other protection.

The matter has been brought more before our notice in consequence of our having been on two days a few hours from home, and having seen some large kitchen gardens, two of which though large were fully cropped, whilst another had plenty of uncropped ground, with whole quarters left for winter vegetables; whilst we had to think where we could find a piece on which to sow the first Cabbages; for almost every bit was crammed, and then we could hardly have enough. Of course in large gardens there is more space to go over, but there is not the same scheming necessary to produce as many crops as possible off the same piece of ground.

Cottagers and allotment-holders often run us hard in making the most of the ground by adopting the simultaneous cropping system—that is, having two or three crops on the same ground at once, or one crop quickly following the other; for instance, this season our old Cabbage quarter has been thrown into wide bed trenches for bedding plants, and is now used for Celery, with Peas on the tops of the ridges. This is the successful mode, but frequently when these trenches were made early we put a little hot dung in them, planted early Potatoes just sprung, with Lettuces and Radishes between the rows. The Radishes and Lettuces with a little protection were just cleared off in time to make way for the Potatoes, which came in early; and with an additional layer of rotten dung, the ground they occupied made an excellent bed for three or four rows of Celery, which was tied up. The Pea ground was not encroached upon for earthing-up until the Peas were gathered, whilst they gave the exact shade required by the Celery in the earliest stages of growth, as in the autumn it needed none. This Celery ground would most likely bear Onions the year following, and be cropped in autumn with Cabbages to stand all next season and over the second winter, the ground then coming in for Peas, Potatoes, and Celery again.

Here we would notice, that many cottagers in this neighbourhood take up their Potatoes before they are very ripe, and

follow with Winter Greens and Turnips, which is, so far, a good plan. Many, however, cut up their Cabbages of the autumn planting even before they are firm and well-hardened in the centre—the state in which we like to see Cabbages at a working man's table—and then follow with fresh young plants of Savoys, or other winter vegetables. Now, if the ground is at all good, or if soapsuds, dish washings, and other fertilising agents can be poured on the Cabbage ground, we have great doubts if anything else will yield the same amount of well-flavoured vegetables as these Cabbage stumps. On some of our first-cut Cabbages we can count four or half a dozen young ones, which will be good firm Cabbages by-and-by, and these will be followed by younger ones, which will produce young Greens during the greater part of the winter, if it be not very severe; in fact, until we clear them off in spring. We like young Coleworts, which we shall plant-out directly, placing them about a foot apart, and they give a fine supply towards the end of autumn and the beginning of winter; but even when they are thus thickly planted and growing vigorously, we do not, space for space, cut the same weight and quantity as we generally do from the old Cabbage stumps. We have been told that the young Coleworts, &c., are sweeter and more tender, but we failed to perceive the difference. Of course, if the old Cabbage stalks were dried-up and stunted they would be hard, but if moderately cared for, the ground surface-forked, manure water given, or a little manure thrown in among them, we are convinced cottage gardeners would find no Greens more profitable than the old Cabbages. Those who like Cabbages firm and soft for the most of the year, will not be disappointed if they keep the Cabbage stumps.

This brings us to the *sowings of Cabbages*. The first sowing of such kinds as Atkins's Matchless, Shilling's Queen, and Enfield Market, we like to make from the 3rd to the 6th of July, following twice afterwards at intervals of a fortnight. If the first sowing receive no check there is little chance of the plants running to seed. That, as in the case of Celery, is more owing to checks than to mere early sowing. From this sowing fine crisp Cabbages are obtained early, and we know nothing more delicious than such a Cabbage just beginning to be firm, and showing the blanched white in the centre. Some of our readers are unfortunate with their Cabbage seed beds. If they sow in dry ground, as it is now with us, the seeds are parched, and come up irregularly. If they water after sowing, the ground, if at all stiff, is apt to cake, and enclose the seeds in a waterproof coat, which excludes the air, and in sunny weather there will be cracks and chinks. It is never advisable, therefore, to sow in very wet ground. When the ground has been too dry on the surface, we have adopted two methods, generally giving the preference to the second. In the first case we tread and rake the ground when mellow after digging, and then water it, leaving it alone until the surface is rather dry. In the second case we prepare the ground in a similar way, and scatter the seeds on the fine surface, then give a gentle pat all over with a clean spade, finally watering through the rose of a watering-pot, giving sufficient to moisten the soil properly, but not excessively, and coming over with the rose two or three times, so that there shall be no running of water on the surface. In a couple of hours or so after this watering, when the surface is hazelled over, we follow with a covering of light, riddled, dryish soil—say about one-eighth of an inch in thickness. The seeds have thus a damp but not too wet a bed, to swell and germinate in, and the dry surfacing secures warmth, by arresting evaporation and the cracking and hardening of the surface, which would be the results of a rapid evaporation from a smooth, damp surface. Of course, when the soil is sufficiently moist, there is no need for such nicety; but when attended to there is every chance of uniform germination and fine healthy seedlings. It is always best not to sow very thickly; but here we may recommend what we rarely practise, as for reasons already stated, our seed beds are always too small, so that we are forced to thin out quickly in order to keep the seedlings sturdy. Last year we heard a great many complaints about bad seeds, and dishonest seedsmen. We believe that in nine cases out of ten the fault lay with the sower.

Hoeing, planting, and watering other crops were our principal operations in the kitchen garden, not forgetting what we presume will be a final hoeing to the main quarter of Onions. There was hardly a small weed to be seen, but a Dutch hoe carefully run between the rows would cut up any invisible ones, and keep the surface loose, thus preventing cracking. Bent down the necks of the second lot of autumn-sown Onions, to increase the size of the bulbs, watered young beds of them for salads, and sowed more for a similar purpose. Sowed also a bed of Early Horn Carrots for autumn and winter use, and successions of Lettuces and Endive, as these can be planted in any corner when ground is scarce. In front of a fence or wall with a north aspect is a good place at this season, or the north side of a raised bank. We have sowed Endive for the main crop. In the end of the month we shall sow more sparingly, as when the plants from this sowing pass the winter, they come in useful in spring, before the Lettuces are sufficiently hearted to be at their best.

In all sowings when the ground is dry, we recommend allotment holders to follow less or more the plan recommended for Cabbage seed, and, unless they are more fortunate than we are, also to net, or adopt other means of *protecting their seed-beds from birds*. We have good beds of Lettuces, Coleworts, &c., just now that have not been netted, but we watched them every day, and some flag-like pieces of black cloth were stuck in the bed, which for the time frightened them. We saw small looking-glasses suspended over seed beds the other day in a large garden, and they were said to be very effectual. We found them useful many years ago. We could not find out the address of the maker. Small glasses, say 3 inches by 5, in a lead or metal frame would not cost much. We trust this may meet the eye of some one who will be able to give more definite information on the subject, as provided deterrents could be made to suit one's purpose, anything would be better in a garden than the poison pellet, or the report of a gun, so inconsistent with the quiet that should ever be associated with the garden.

Decayed Manure and Leaf Mould.—We are becoming short of these. We have begun bottoming a rather deep earth pit which has not been so summarily treated for three years, and we shall obtain a fine lot of material which the passer-by would have known nothing about. We have lately cleared off from this pit a fine crop of Potatoes, which were at first protected by old sashes and litter. The gardener makes a mistake if he become satisfied with hot water for everything. Without such beds to go to, we might look out in vain for materials for mulching flower beds, leaf mould for compost, &c. Another matter—It is always bad policy to have much short grass or stable litter lying about doing nothing. We have a rather large heap of grass and some litter now, and we shall soon have it out of sight, well mingled in this hole; and covered with rotten dung and soil, it will be of use for many purposes, and afford material for giving heat, by mixing, for late autumn and early spring crops. Our next lot of short grass, we shall use for bottoming our rubbish heap, which will cause it to heat, and in varied layers will make it rich in nitrogenous matter. This heating helps to kill many weeds and seeds of weeds, and thus used the necessary rubbish heap becomes an excellent enriching compost. Even if the supply of fermenting material is good, it is generally bad policy to have huge heaps lying about doing nothing. It conjures up ideas that it might as well be employed elsewhere.

ORNAMENTAL DEPARTMENT.

Besides the usual routine of grass-cutting, we shall only refer to three things especially in the ornamental department.

We have, in the first place, been putting in a lot of various kinds of *Pink cuttings and pipings*. These will strike well enough in sandy soil on a shady border under a hand-light, or a cover of paper and calico. When dispatch is desired, they strike more quickly and make stronger plants with a little heat below them. We prepared, therefore, a bed of grass and litter about 15 inches deep, trod it rather firm, covered it with 3 inches of half-rotten leaves, and then with a layer of somewhat rough soil, followed by finer, and road sand on the surface. We covered with hand-lights, and as the spot was sunny, shading will be necessary by day, with the glasses shut, and a little air must be left on at night. In such a place Cloves and the hardier Carnations strike well, and thus save the trouble of layering them. Nothing yet equals this tribe of plants for the bouquet, vase, or goblet of cut flowers, and quantity and rich scent will under such circumstances be more thought of than fine shape and quality. Many of the best, however, bloom freely in their second year when moderately well treated. As previously remarked, we rarely use a knife in making such cuttings, but catch the shoot below a joint in the left hand, and pull it out of the joint by the right hand; generally it then comes out with a cleaner and clearer base than any knife could make. If a little film should adhere, that may be removed by a sharp knife; but out of some hundreds the other day the knife was never required, as the cuttings or pipings were short and

robust, owing to the dry weather lately. There was little necessity for shortening the points of the leaves, as under such circumstances when left untouched they root all the sooner, if shading and air-giving be properly attended to.

The second matter was watering, and chiefly the Calceolarias and the Verbenas. The different-coloured Scarlet Pelargoniums had but little water given, as the earth about them was moist beneath, not warm enough to promote rapid growth and free blooming, and watering would if anything have made the ground colder. We have nowhere as yet seen well-bloomed beds of Scarlet Pelargoniums out of doors, except where they had been turned out as good flowering plants. A few sunny days will enable them to overtake the Calceolarias that delight in a moister and cooler soil.

To keep the ground cool and moist about them we have mulched, with the rotten dung referred to, the most of our Calceolarias, having a vivid recollection of the dryness and the heat of the last summer. This we did by breaking up the manure rather finely with the points of a fork, and spreading it thinly by the hand, after being laid in openings in small spadesful. If the season threatens to be dry, we shall serve Pelargoniums in the same way when once the ground is more heated. What will come to the outside of beds and borders will pass through an inch sieve. This plan is good for saving watering.—R. F.

COVENT GARDEN MARKET.—July 7.

Supply and demand are about balanced as regards English produce; foreign produce is somewhat in excess of our requirements, and inferior in quality. There have been large arrivals of Potatoes, both by rail and water. Old ones are now neglected; the new meet with a fair demand.

TRADE CATALOGUE RECEIVED.

J. J. De Beucher, Rue Carnot, 105-107, Antwerp.—*Descriptions of New Seedling Variegated Zonal Pelargoniums. With Coloured Plate.*

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely to The Editors of the Journal of Horticulture, &c.*, 171, *Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week

Books (*A Beginner in Botany*).—Henfrey's "Rudiments of Botany."

Pyrethrums (*D. H.*).—They will be fully treated of in an early number.

Select Roses for Covering Arches and Pillars (*K. M. K.*).—"'Which are the best eight Roses for covering wire arches and for pillars?' is a question somewhat vague. Nothing is said as to whether summer Roses or autumnal ones are required, I presume autumnals are desired. I should select from the following:—Acidalie, the Red Bengal, Gloire de Dijon, Céline Forestier, Baronne Prevost, Triomphe de Rennes, Duc de Cazes, Anna Alexieff, and Ophirie. With regard to the stock, I think the Manetti is the best for climbers.—W. F. Radclyffe."

Aphides on Roses (*A Lady in Cheshire*).—Syringe the trees with tobacco water made by pouring at the rate of a gallon of boiling water on each 2 ozs. of tobacco, letting it cool, and then straining. Mulch over the roots of the trees, and keep them well watered in dry weather. Repeat the syringing as often as an aphis is found on the Roses.

Roses to Bloom in January (*H. M. K.*).—It is very difficult to have Roses in flower at that season. Last year's cuttings would be most suitable. They should be taken up now with good balls, potted, placed in a cold frame for about ten days and shaded, keeping moist; afterwards expose them fully, placing them in a warm situation, and pinching off all flower-buds. The old plants should be treated in the same way, setting them near a south wall, and keeping them rather dry at the roots, so that the leaves may fall, while the shoots are prevented from shrivelling. In that position they should remain for six weeks; then repot them in a compost of two parts turfy loam, one part old cow dung, or well-reduced manure, and one part leaf mould, with one-sixth part of sharp sand. They should be kept rather dry for a fortnight, then prune them, and place in a cold pit or frame, setting the pots on coal ashes. They ought to be sprinkled with water twice a-day and kept rather close, but give air enough to keep the temperature from rising above 75°. When they have shoots an inch long admit air day and night, keep them well supplied with water, and frequently sprinkle their tops. They may remain in the pit or frame until the nights become frosty, and even after that if protection from frost be given, but when that cannot be afforded they should be removed to a house having a night temperature of from 45° to 50°, and 55° by day, with a rise of 10° or 15° from sun heat. To bloom the plants a night temperature of from 50° to 55° will be required. They cannot have too light and airy a position, and the aphis must be destroyed by fumigation with tobacco, and mildew by dusting with flowers of sulphur. As your plants are not prepared, we have little hope of your success, but you can, nevertheless, try, starting half the plants as above, and the other half early in November, giving for the first fortnight a night temperature of 45°, and then increasing it to between 50 and 55° in another fortnight, at which temperature keep the plants until they come into bloom.

Garden Wall (*Sussex*).—The wall should be 12 feet high above the ground line, as that height is the most suitable for the majority of fruit trees. We consider it very desirable to have the walls wired, but the wires ought to be so fixed that they will not be farther from the wall than three-quarters of an inch, and better if only half an inch. The foliage does not appear to like the current between the wires and the wall, and the nearer the wires are to the wall the better, so long as a sufficient space is left for passing the tying material between the wires and the wall. No. 10 galvanised wire is best, and for Peach and Apricot trees the wires should be 3½ inches apart, or in every course of bricks; whilst for Plum, Cherry, and Pear trees fan-trained, the wires may be 6 inches apart; for Pear trees trained horizontally they should be 1 foot apart.

Heating a Small Greenhouse (*S. E. A. A.*).—We refer again to your case, page 431, and we advised a brick stove because the place is small. We had no idea of your having a flue. A small iron stove, costing with smoke piping from 50s. to 60s., would answer the same purpose, but the heat is not so kindly as from a brick stove. The brick we merely substitute for the iron. If you could put the stove in the middle of the north side, all the better; if not, it will do at the north corner marked ×. The brick stove should be 28 inches square, and from 3½ feet in height. If the width in the corner were rather too much for the narrow house, you could borrow a piece from the wall. Lay out the square named on the floor with brick on bed. In the centre of this, in front, fix a close-fitting ashpit door. Mark out a space 7 inches wide, and to within 10 inches of the opposite side; that will be the base of the ashpit. Build all round until you rise a little higher than your ashpit door, and place bars across for the bottom of the fireplace, which is to be 8 inches wide and 8 inches deep, formed of fire bricks, or four lumps of fire clay. Build up with brick to the necessary height, and then fix the furnace door—a double one; use brickwork for the necessary height above, and cover at top with a thick piece of iron or a slab of stone, and in either case have an evaporating pan. Three or 4 inches from the top have a 4-inch pipe to go through the back wall, and rise outside as a chimney. With close-fitting furnace doors, nothing more will be needed; but if the ashpit door cannot be well regulated, a thin slab of fire clay should stand a few inches in front of the chimney pipe, so that the smoke and heat can pass by the sides instead of more directly. With a close-fitting ashpit door this is not needed. The bricks should be laid in good mortar, the fire bricks and lumps with fire clay. Coke or the best cinders only should be used, and in cleaning and lighting, the ashes should be damped previously, to prevent dust. We are presuming that the furnace and ashpit doors are inside the house. With a little more labour you could have these doors outside the house, by cutting out a part of your back wall, and thus you would save room inside the house. In such a case, however, it is well in stoves not to have the feeding door and the outlet chimney on the same side. You could easily have the chimney from the top or the opposite side, and take it up the back wall of the house, and so out at the roof. We once had a stove which worked well, and from the want of an iron plate or a flagstone we covered the top with tiles, supported on flat iron bars, and then with brick on bed set in fire clay. However you build such a stove, it should not have a fire in it for a fortnight at least, as then the mortar, &c., will be well set. Such a stove would give heat enough for a house three times the size, and no other plan is so cheap and simple. By feeding outside you will have no dust. What we stated as to piping would be ample in your case. The rules for calculating are very varied, and a great many circumstances must be taken into consideration, but almost any description of house may thus be calculated:—To the whole surface of glass exposed add one-third, then multiply by the number of degrees the house is to be kept at above the external air, the product, divided by 190, will give the quantity of piping required in superficial feet. The mere number of cubic feet of air enclosed, as to which you wish information, would be no guide, as a house bounded by walls would be different from a house like a hand-light—

glass all round; but we may state that for a lean-to house, dividing the cubic feet of air by 30, will give the number of feet of 4-inch piping, sufficient to keep the house at 60°, except in very cold weather. To keep such a house at 70°, divide the cubic feet of air by 20. The large conservatory at Chatsworth has been kept at 60° with 1 foot of 4-inch piping to 30 cubic feet of air; but this result is greatly owing to the bulk of air enclosed. In low span-roofed houses, glass all round, it would require 1 foot of piping to from 18 to 20 cubic feet of air. The size of piping generally goes in the ratio of 2, 3, 4. Thus, 200 feet of 4-inch piping will be equal to 300 feet of 3 inches, and 400 feet of 2 inches. The smaller sizes are sooner heated.

Early Strawberry (*K. M. H.*).—Vicomtesse Hericart de Thury.

Growing Mushrooms in a Cow House (*M. L. D.*).—Than your four stalls in a dark, or almost entirely dark cow house, no place could be better for Mushroom beds. Without other heat you cannot force well, except from the heat of the beds. The best material to use would be three parts horse droppings, one part short litter, and one part turfy loam in rough pieces about the size of eggs. We have scarcely ever wanted Mushrooms for many years, and we never could make a bed of horse droppings, but were glad of some for surfacing the bed. The next best material is well-wrought manure, such as gardeners in general use for a Cucumber bed, and a couple of inches of droppings on the surface. For spring and autumn, a bed of some 12 inches of droppings would be ample, and less would do for summer. If the bed is a mixture, as above, the depth should be at least 15 inches; and for winter it should be from 18 inches to 2 feet in depth. With the four stalls we would have four successions. In winter you must keep the beds warm with dry covering over them, and in very cold weather you could have a heap of fermenting dung, or dung and leaves, in the passage behind the stalls, and this would give a good preparation for material for the bottom of a fresh bed. With such a dark house, and, we presume, rather thick walls, we should have no difficulty with Mushrooms. Provided the material is plentiful, the fermenting material in the passage would maintain a warm humid atmosphere in the place during winter. In summer it would be necessary to sprinkle the walls and floor to keep the place cool, and avoid keen draughts of air. One essential is not to kill the spawn with too much warmth, and another is neither to starve it with dryness, nor flood it with moisture. We presume you understand these points.

Protecting Wall Fruit Trees (*W. R. B.*).—The best moveable protection for a Peach wall would be calico sheeting, which you could pull up and down. The cheapest permanent protection is a house of glass and wood, in the orchard-house style, using rafter sash bars and wide glass, and thus dispensing with heavy rafters and moveable sashes. We presume you know how these are made. The cheapest moveable sashes, such as you see advertised in our columns, will cost much more, but then you can move them from place to place as you like.

Ventilating an Unheated Peach House (*J. R. W.*).—If you have no means of making ventilators in the back wall, you will require an opening at the apex, equal to from 10 to 12 inches all the way along. You will need the same in front. If the proposed windows are to be of glass in front, then all will be well; but if they are to be wood, then we would dispense with the bricks, have fixed glass where the ventilators are shown to be in front, and wooden ones of 10 or 11 inches wide below them, nearer the ground; but your plan is sure to answer. Glass ventilators are not so good for folding down as wooden ones, still they may be fixed by rods to open only certain lengths.

Tricolor and Bicolor Pelargoniums in a Frame (*Q. Q.*).—The colour of both would be improved by the lights being taken off entirely.

Mastic L'Homme Lefort (*Idem*).—The mastic is successful as an application for budding Roses or any other plant, but it is safer to tie slightly before applying the mastic.

Lobelias (*Idem*).—There are many now like L. cardinalis, but much handsomer, they are also of stronger habit, and are more hardy. Among them the following may be instanced:—Comet, Dazzle, Glitter, and Vivid. Lobelia Queen Victoria answers to your description.

Fruiting of the Indiarubber Plant (*B. H.*).—This is not of very common occurrence. We have, however, seen a good many examples of its having fruited, especially during the past winter and spring, chiefly on plants which had at some period been checked in their growth, as in your case, by losing the point bud, or in consequence of the thorough ripening of the wood during the hot summer of 1868. Stunted or half-starved plants also produce fruit freely.

Bigarreau Cherry Casting its Fruit (*Amateur*).—We think it will be advisable for you, and most satisfactory, to take up your Cherry tree carefully in the beginning of October, saving all the roots you possibly can, when, after securing proper drainage, if necessary renew the soil completely around its roots to the depth of 2 feet or so. Allow the tree liberty of action for its branches, prune but sparingly, and we doubt not you will be repaid for the trouble.

Rose Leaves Spotted (*Idem*).—Your Rose trees, judging from the leaves sent, are suffering from the effects of cold—cold weather and cold, sour soil. Remedy the latter.

Liquid Manure for Out-door Vines—Thinning Berries (*Idem*).—The best liquid manure for Vines is that from a cow shed. They might be supplied with it once a-week, diluted with water, or better on a rainy day, from the time of the setting of the berry to the commencement of colouring. Quantity must be entirely regulated by the size and strength of the plant, and the extent and quality of the soil in the border. They will stand much in a well-drained, porous soil. Commence to thin the berries on the bunches as soon as they are set. The operation may be finished at once, or repeated. The object is to this, so that the berries when fully grown may not interfere or crowd against one another to prevent their swelling to the full size.

Planting Vines in an Inside Border (*Reader*).—The best time for planting Vines is during this month, and the best Vines for planting are those which have been started from eyes in the spring of the same year, which in July, if properly managed, should be fine, healthy, free-growing plants in 10-inch pots, and from 4 to 6 feet in height. They should be planted out before the roots become much matted round the sides of the pot, so that in planting the roots may be but little disturbed, and the plants continue to grow unchecked in a most luxuriant manner. Vines planted thus, having their roots so well established in the soil before winter, are capable of bearing, and would bear, fruit as well in the following spring as if they had remained in a pot. Having regard, however, to the permanent and future condition of planted-out Vines, it is not policy to allow them to bear fruit. To plant in September or October is somewhat too late, as by that time the natural season of the growth of the Vine is nearly over, so that the Vines can establish themselves but little in the new soil until the following spring. To excite growth so late in the season, and during winter, by littering, watering, &c., will prove not only useless but positively injurious. The littering is useless, and the watering injurious. Your efforts ought rather to be to keep the roots warm and dry, so as to secure the early ripening of the wood, for by such means only can your object be attained. Cutting back the canes and growing them on again must depend altogether upon their strength. Vines break all the stronger by being allowed to do so naturally—that is, with as little artificial assistance as possible.

Putteridgebury (*A Gardener, Herts*).—We know nothing as to the gardens at Putteridgebury being open to the public, but any gardener may see them by making application in the usual way.

Names of Plants (*S. J. H.*).—The Ribbon Grass is Phalaris arundinacea. The other seems to be Vinca major variegata, or Variegated Larger Periwinkle. (*Miss H.*).—Sedum Sieboldii variegatum. (*F. P.*).—1, Polygonum convolvulus; 2, Solanum dulcamara; 3, Centranthus ruber. (*Margaret*).—1, Lamium maculatum; 2, Rhododendron hirsutum. (*An Old Subscriber*).—2, Spiræa prunifolia. (*G. S.*).—We believe your Iris to be I. versicolor, but your specimen was quite smashed in coming through the post. Iris bicolor, *Lindl.*, usually known as Dietes bicolor, *Sweet*, has clear yellow flowers with a black blotch at the base of each sepal. It is a native of the Cape of Good Hope, and is usually treated in cultivation as a hothouse plant. I. versicolor, *Lindl.*, is a North-American plant, hardy in cultivation, and bears purplish violet flowers, the sepals being whitish at the base with a central streak of yellow.

POULTRY, BEE, AND PIGEON CHRONICLE.

NORTHAMPTON POULTRY SHOW.

For many years past the Northampton Agricultural Society has had good reason to feel proud of that portion of its annual Exhibition devoted to poultry. In fact, from year to year the public interest in this department seems to increase, and under the management of energetic Stewards, the poultry arrangements have become so complete as to admit of but little, if any improvement. The tent accommodation is excellent, and Messrs. Turners' pens are now too well known to require any special description, and the zeal shown by each member to maintain the Society's present high standard in poultry is most commendable. *Dorkings* invariably stand pre-eminent at the Northampton Shows, and the rivalry in these particular classes is always intense. Many specimens this year of extraordinary size in the Dorking classes proved, however, "as miserable to look at as they were comfortless to themselves," gouty feet being very prevalent. With many birds the ball of the foot was increased to the size of half of a child's playball, and so intensely sensitive, that the slightest pressure between the toes evidently gave the sufferer the most exquisite pain, and the fowls could only move with extreme difficulty. Overfeeding, a contracted range, and too lofty perches, are the causes of this generally incurable complaint. Some very early hatched chickens were shown both among *Dorkings* and *Spanish* fowls. A pen of early Rouen *Ducklings* were equally worthy of note. Mr. Fowler and Mrs. Seamons, of Aylesbury, of world-wide reputation, were competitors,

with five pens of such Aylesbury *Ducks* as have rarely been seen together. Mrs. Seamons taking the first prize, Mr. Fowler the second, and the other three pens being highly commended. For *Geese* Mr. Fowler was first, and Mrs. Seamons second. There were many good *Game* fowls, but the *Game Bantams* were poor.

Of *Pigeons* the entry, though small, was unusually good, Mr. Yardley, of Birmingham, being the successful competitor. The weather was fine and dry, and everything turned out as successful as could be desired. The number of ladies and children on the grounds was beyond precedent.

Dorkings (Any age or colour).—1, R. Wood, Clapton, Thrapstone. 2, J. Longland, Grendon, Northampton. 3, J. K. Fowler, Aylesbury. *c*, J. Longland; R. Sykes, Geddington, Kettering. *Hens.*—1, T. Tatham, Kingsthorpe (Coloured). 2, R. Wood (Coloured). *hc*, J. Longland (Coloured). *Cockerel and Pullet.*—1 and 2, H. Yardley, Birmingham. 3, J. Longland. *Pullets.*—1, J. Longland. 2, R. Wood. *Cock.*—1 and 2, J. Longland. 3, H. Yardley. *hc*, R. Wood. *c*, J. F. Loveridge, Newark-on-Trent; T. Tatham; R. Wood.

Spanish.—1, W. R. Bull, Newport Pagnell. 2, J. Stephens, Walsall. 3, C. Wright, Northampton. *c*, J. T. Parker, Northampton; C. Wright. *Cock.*—1, W. R. Bull. 2, J. T. Parker. *c*, J. Stephens. *Chickens.*—1, J. T. Parker. 2, C. Wright.

Game.—*Cock and Hen* (Any age or colour).—1 and 2, Capt. Wetherell, Loddington, Kettering (Black-breasted Reds). 3, S. Deacon, Polebrooke Hall, Oundle. *Two Hens.*—1, J. D. Blestoe, Grendon Hall, Northampton. 2, S. Deacon. *Cock* (any age).—1, Capt. Wetherell (Black Red). 2 and 3, A. J. Fludyer, Ayston Hall, Uppingham (Brown-breasted Red and Duckwing. *c*, Capt. Wetherell (Black Red).

Cochin China (Any age or colour).—*Cock and Hen.*—1, W. A. Taylor, Manchester. 2, J. N. Beasley, Pitsford Hall, Northampton (Buff). 3, J. Stephens (Partridge). *hc*, J. K. Fowler (Partridge). *c*, J. H. Dawes, Moseley Hall, Birmingham (Buff); J. Stephens (Partridge); J. B. Bletsoe (White); J. Longland. *Cock and Pullet.*—1, W. A. Taylor. 2, J. K. Fowler (Partridge). *c*, J. Longland. *Cock.*—1, W. A. Taylor. 2, J. Stephens (Partridge). *c*, C. Wright (Buff); J. Longland.

Hamburghs (Any age or variety).—*Cock and Hen.*—1, W. A. Taylor (Silver-spangled). 2, F. Collins, Daventry (Golden-spangled). *hc*, J. F. Loveridge, Newark-on-Trent (Golden-spangled).

Bantams (Any age or colour).—*Cock and Hen.*—1, J. D. Bletsoe (Game). 2, W. Barford, Aylesbury (Black Red Game). *c*, Capt. Wetherell (Black Red Game); J. K. Fowler (Game).

Any other Distinct Breed.—*Cock and Hen.*—1, Capt. Wetherell (Crève-Cœur). 2, J. K. Fowler (French). 3, J. Beasley, Chapel Brampton (Japanese Curling). *c*, J. H. Dawes (Houdans).

Geese (Any colour).—1, J. K. Fowler (Toulouse). 2, Mrs. M. Seamons. *hc*, R. Sykes, Geddington, Kettering.

Ducks (Aylesbury).—1, Mrs. M. Seamons. 2, J. K. Fowler. *hc*, Mrs. M. Seamons; J. K. Fowler. *c*, S. Deacon.

Ducks (Rouen).—1, J. K. Fowler. 2, R. Wood, Clapton, Thrapstone. *c*, R. J. Harradine, Kettering.

Ducks (Any other variety).—1, J. K. Fowler (Buenos Ayres). 2, T. G. West, Dallington (Muscovy). *hc*, W. R. Bull, Newport Pagnell (Black East Indian).

Turkeys (Any colour).—1, J. N. Beasley (Cambridgeshire).

Selling Class.—1, J. Stephens (Spanish). 2, J. Longland, Northampton (Dorkings). 3, C. Wright (Buff Cochin-China). *c*, T. G. West, Dallington (Muscovy); H. Yardley; J. W. Gardom, Butterton Park, Newcastle, Staffordshire (Crève-Cœur).

Sweepstakes for Pigeons.—1 and 2, H. Yardley (Satinettes and Almonds). *hc*, E. F. Payling, St. Peterborough (Black Carriers).

The Judge was Edward Hewitt, Esq., of Sparkbrook, Birmingham.

IPSWICH POULTRY SHOW.

There appears to be some peculiar difficulty in conveying poultry to Ipswich in time for the Exhibition, thirty pens of fowls being empty at the hour appointed to commence judging. From the inadvertance of one of the principal exhibitors of Game fowls, five pens of the most meritorious birds had to be passed over, as the birds were shown in pairs instead of as single cocks, and in pairs of hens.

Most of the classes were very good, *Game* and *Game Bantams* particularly so. The *Dorkings* were a very good collection, and the *Spanish* have been rarely excelled. The *Brahmas*, whether Light or Dark-coloured, were of high character. The *Cochin-Chinas*, especially the Buff, were excellent, though many good Partridge-coloured ones are here worthy of mention. French fowls showed a good entry, and the *Hamburghs* and *Polands*, though not numerous, were praiseworthy. The Aylesbury *Ducks* could not be bettered, Mrs. Seamons and Mr. Fowler dividing the premiums. No show could rank more highly in *Pigeons*, and reference to the prize list will show the amount of competition. The weather being fine, the Show was a complete success.

Game (Black-breasted and other Reds).—*Cock.*—1, Cup, and 3, W. Gilliver, Polesworth. 2, W. Boyes, Beverley. *hc*, H. E. Martin (Brown Red); W. Gilliver (Brown Red).

Game (Any other variety).—*Cock.*—1, W. Boyes. 2 and *c*, W. Gilliver (Piles). 3, H. E. Martin (Duckwing). *Hens or Pullets.*—1 and 2, S. Matthew, Stowmarket.

Dorkings (Any variety).—*Cock.*—1, W. Tippler, Roxwell, Chelmsford (White). 2 and *hc*, H. Lingwood. 3, J. Frost, Parham (Coloured). *Hens or Pullets.*—1 Cup and 3, for best pen of Dorkings or Spanish, D. C. Campbell (Coloured). 2, F. Parlett. *hc*, H. Lingwood; J. Frost (Coloured).

Spanish.—*Cock.*—1, J. Laming. 2, P. H. Jones, Fulham. 3, F. James, Peckham. *Hens or Pullets.*—1 and *hc*, F. James. 2, P. H. Jones. 3, J. Laming.

Brahma Pootra (Dark).—*Cock.*—1, and Cup, Mrs. Burrell, Stoke Park, Ipswich. 2, H. Dowsett, Pleshey, Chelmsford. 3, Mrs. A. Hurt, Alderwasley, Derby. *hc*, H. Loe; Mrs. A. Hurt; Mrs. Burrell.

Brahma Pootra (Light).—*Cock.*—1, J. Pares, Postford, Guildford. 2, H. Dowsett. 3, H. M. Maynard, Holmewood, Isle of Wight. *hc*, F. Crook, Forest Hill. *c*, H. Dowsett.

Brahma Pootra (Any variety).—*Hens or Pullets.*—1 and 2, Mrs. A. Hurt (Dark). 3, F. Crook. *hc*, H. Dowsett (Light); Mrs. A. Hurt (Dark).

Cochin-China (Cinnamon or Buff).—*Cock.*—1 Cup, and 2, H. Mapplebeck, Woodfield, Moseley, near Birmingham. 3, Mrs. Woodcock, Rearsby. *hc*, H. Lingwood (Buff); H. Loe, Appuldurcombe; W. A. Taylor, Manchester. *c*, Mrs. Burrell.

Cochin-China (Any other colour).—*Cock.*—1 and 3, Mrs. A. Williamson (White). 2, W. A. Taylor. *hc*, Viscountess Malden. *c*, J. K. Fowler, Aylesbury.

Cochin-China (Any variety).—*Hens or Pullets.*—1, W. A. Taylor. 2, H. Mapplebeck (Buff). 3, Mrs. Burrell (Buff). *c*, S. Felgate, Ipswich (White).

Crève-Cœurs, Houdans, and La Fleche.—1, P. H. Jones (Houdans). 2, W. Tippler (La Flèche). 3, Viscountess Malden (Houdans). *hc*, P. H. Jones; J. K. Fowler; Lady L. Charteris (Crève-Cœura). *c*, Lady L. Charteris (Houdans).

Hamburghs (Golden-pencilled).—*Cock.*—1 and Cup, W. K. Tickner, Ipswich. 2, J. Laming. 3, F. Pittis, jun., Newport, Isle of Wight.

Hamburghs (Silver-pencilled).—*Cock.*—1, J. Laming. 2, F. Pittis, jun.

Hamburghs (Golden-spangled).—*Cock.*—1 and Cup, J. Laming. 3, F. Pittis, jun.

Hamburghs (Silver-spangled).—*Cock.*—1, Mrs. Burrell. 2, J. Laming. 3, F. Pittis, jun.

Hamburghs (Any variety).—*Hens or Pullets.*—1, W. K. Tickner (Golden-pencilled). 2 and 3, Mrs. Burrell (Silver-pencilled and Silver-spangled). *hc*, F. Pittis, jun.; J. Laming.

Polish (Any variety).—1, J. Laming. 2, D. Mutton, Brighton (Black). 3, Mrs. E. Proctor, Hull. *c*, D. Mutton (Black); Mrs. Burrell (Silver).

Game Bantams (Black-breasted).—1, Cup, and *hc*, W. T. Griffin, Bayswater. 2 and 3, W. F. Entwisle, Leeds. *c*, Hon. Mrs. Paget; J. W. Kelleway.

Game Bantams (Any other variety).—1, H. Loe. 2, W. Adams, Ipswich (Duckwing). 3, Hon. Mrs. Paget (Duckwing).

Bantams (Gold or Silver Sebrights).—1, Countess Winterton (Gold). 2 and 3, W. T. Griffin.

Bantams (Black, White, or other variety).—1, S. S. Mossop, Long Sutton. 2, T. C. Harrison (Black). 3, J. Dawes, Birmingham (Japanese). *hc*, H. M. Maynard (Black); S. & R. Ashton (Black).

Bantams (Any variety).—1, W. Adams (Duckwings). 2, H. Leech, Woolpit (Duckwing). 3, W. F. Entwistle.

Any other Variety not Before Mentioned.—1, J. Laming (Black Hamburghs). 2, Mrs. Burrell (Silkies).

Selling Class (Any variety).—1, H. Loe. 2, D. C. Campbell (Dorking). 3, Mrs. Burrell. *hc*, Viscount Turnour, Shillinglee Park, Petworth (Dorkings); W. K. Tickner (Golden-pencilled Hamburghs); T. Roper (Dorkings). *c*, A. Beaumont, Ipswich; D. C. Campbell, Brentwood (Dark Brahmas); Mrs. E. Proctor (Silver Polands).

Ducks (Rouen).—1, J. K. Fowler. 2, Withheld. 3, F. Parlett.

Ducks (Aylesbury).—1 and 3, Mrs. M. Seamons, Hartwell, Aylesbury. 2, J. K. Fowler. *hc*, J. K. Fowler; Mrs. Burrell.

Ducks (Any other variety).—1 and 3, T. C. Harrison, Hull. 2, S. & R. Ashton, Mottram. *c*, J. Pares.

Turkeys (Any colour).—1, M. Kew (Cambridge). 2, A. Mayhew. *hc*, J. Berners, Woolverston Park (Cross with American).

Geese (Any variety).—1, Mrs. M. Seamons. 2, J. K. Fowler. *hc*, W. H. Horne, Drinkstone (Toulouse).

PIGEONS.

Carriers (Any colour).—1 and 2, R. Fulton, Deptford. *hc*, J. Hawley, Bingley.

Pouter (Any colour).—1 and 2, R. Fulton.

Tumblers (Any variety).—1 and 2, R. Fulton (Almonds and Mottles). *hc*, P. H. Jones (Almonds); R. Fulton (Self-coloured); J. Hawley.

Jacobins (Any colour).—1 and *hc*, P. H. Jones. 2, R. Fulton. *c*, J. Hawley.

Fantails (Any colour).—1, J. Hawley. 2, W. H. Tomlinson, Newark. *hc*, Hon. Mrs. Paget (Black); P. H. Jones; H. Yardley, Birmingham; R. Fulton.

Trumpeters (Any colour).—1, J. Hawley. 2, Hon. Mrs. Paget (Black). *hc*, J. Hawley.

Turbits (Any colour).—1 and 2, P. H. Jones. *hc*, H. Yardley.

Barbs (Any colour).—1, R. Fulton. 2, H. Yardley. *hc*, P. H. Jones; R. Fulton.

Magpies (Any colour).—1, P. H. Jones. 2 and *c*, J. Hawley. *hc*, H. Yardley.

Any other Variety.—1 and *c*, P. H. Jones (Nuns and Manes). 2, Hon. Mrs. Paget (Ice). *hc*, J. Hawley; P. H. Jones (Owls).

Selling Class (Any variety).—1 and *hc*, J. Hawley. 2, P. H. Jones. *c*, J. Hawley; T. Roper (Barbs).

CAGE BIRDS.

Canaries.—*Clear Yellow.*—1 and 2, T. Fenn, Ipswich. *Clear Mealy.*—1, R. W. B. Dix, Ipswich. 2 and *hc*, T. Fenn. *Mottled Yellow.*—1 and 2, T. Fenn. *Mottled Mealy.*—1 and 2, T. Fenn. *Mottled Crested Yellow.*—1 and 2, T. Fenn. *Mottled Crested Mealy.*—1 and 2, T. Fenn. *Belgian.*—1, R. W. B. Dix. *Lizard.*—1, T. Fenn. 2, J. A. Ransome. *hc*, R. W. B. Dix.

Goldfinch Mule.—1 and 2, T. Fenn (Yellow and Mealy).

Selling Class (Any variety).—1, 2, and *c*, T. Fenn (Yellow).

Any other English or Foreign Cage Bird not Mentioned in the Above Classes.—1 and 2, T. Roper (Cockatoo). *hc*, T. Fenn (Goldfinch and Bullfinch).

Extra Class.—*vhc* and *c*, J. A. Ransome (Lizard and Yellow Canaries)

Edward Hewitt, Esq., of Sparkbrook, Birmingham, was the Judge.

KETTERING POULTRY SHOW.

The Show of this year has proved most successful, and far in advance of its predecessor. Most of the classes were well filled, those for *Game*, *Spanish*, and *Hamburghs* especially so. Strange to say, only a single pen of *Brahmas* was entered, but it was good. The *Turkeys* would have been creditable to any show. *Pigeons* were numerous and excellent. The display of *Foreign birds*, for which there were especial classes, was one of the most striking features of the Show. Some exceedingly well-shown Bishop birds, Weaver birds, and a variety of

Parrots, considerably interested the visitors, whilst fine specimens of the Blue and Yellow Macaw were much petted by most of the bystanders. It was one of the most confiding of this species we remember to have seen. The weather being exceedingly good, the attendance was most satisfactory.

DORKINGS (Any variety).—1, J. Longland, Greendon. 2, R. Wood, Clapton. 3, T. Burnaby, Pipewell. *Chickens.*—1, Rev. E. Bartrum, Berkhampsted, Herts. 2, R. Wood. *c*, J. Sheffield. *Hens.*—1, H. Wyman, Broughton. 2, J. Longland. *hc*, R. Wood; O. E. Cresswell, Haoworth Rectory, Hounslow. *c*, J. Sheffield; R. L. Garrat', Thorpe Malsor.

GAME (Any variety).—1 and 2, Capt. J. T. Wetherall, Loddington.

GAME BANTAMS.—1, Capt. J. T. Wetherall, Luddington. 2, J. R. Robinson, Sunderland.

COCHINS (Any variety).—1, J. N. Beasley. 2, J. Barber, Kettering. *hc*, J. Longland. *c*, G R. Chettle, Kettering; C. Houghton, Kettering.

BRAHMAS (Light or Dark).—1, Hon. Mrs. Baillie Hamilton, Ridgmount, Woburn.

SPANISH (Any variety).—1, W. R. Bull, Newport Pagnell. 2, H. Pickles, jun., Esrby, Skipton. *hc*, G. R. Chettle, Kettering; J. J. Sharp, Kettering.

HAMBURGHS (Gold and Silver-pencilled).—1, W. K. Tickman, Ipswich. 2, H. Pickles, jun.

HAMBURGHS (Gold and Silver-spangled).—1, H. Pickles, jon. 2, J. F. Loversidge, Newark.

ANY OTHER DISTINCT VARIETY NOT PREVIOUSLY MENTIONED.—1, Capt. J. T. Wethersll (Crève-Cœur). 2, H. Wynaham, Wawne, Beverley (Crève-Cœur).

ANY VARIETY.—*Chickens.*—1, Hon. Mrs. Baillie Hamilton (Dark Brahma). 2, C. Banberry, Peon Fields, Wolverhsmpton (Buff Cochins). *hc*, J. Longland (Cochins); W. Nottage, Northampton (Partridge Cochins).

LOCAL CLASS (Any variety).—1, Cleaver & Johnson, Kettering. 2, T. Burnaby, Pipewell.

SELLING CLASS.—1 and 2, G. R. Chettle, Kettering (Spanish and Buff Cochin.)

DUCKS (Rouen).—1, R. Wood, Clapton. 2, T. Burnaby. *hc*, R. Craddock, Rushton Lodge.

DUCKS (Aylesbury).—1, B. L. Garrat, Thorpe Malsor. 2, W. Grant, Northampton. *c*, R. J. Harradine, Kettering.

DUCKS (Any other variety).—1, W. Watkinson, Bunghton Farm. 2, J. J. Sharp, Kettering.

GEESE (Any variety).—1, R. Sykes, Geddington. 2, Withheld.

TURKEYS (Any variety).—1, J. N. Beasley, Pitsford Hall. 2, J. Sheffield, Geddington Grange. *c*, M. Kew, Overton.

SWEEPSTAKES FOR SINGLE GAME COCK. — 1, R. Hall, Cambridge. *hc*, Capt. J. T. Wetherall.

PIGEONS.

CARRIERS (Any colour).—1, E. Walker, Leicester. 2, H. Yardley, Birmingham.

POUTERS (Any colour).—1, S. Horn, Kettering. 2, R. T. Payling, Peterborough. *hc*, J. Barber, Kettering. *c*, H. Yardley.

TUMBLERS (Any variety)—1, H. Yardley. 2, C. Allsn, Kettering (Agates, Almond.) *c*, H. Lamb, Kettering.

BARBS (Any colour).—1, J. Spence, Kettering. 2, H. Yardley. *c*, W. Beaver, Kettering.

JACOBINS (Any colour).—1, H. Yardley. 2, J. Spence.

FANTAILS (Any colour).—1, J. Spence. 2, H. Yardley. *hc*, W. H. Tomlinson, Newark.

ANY OTHER DISTINCT VARIETY.—1, H. Yardley. 2, W. H. Tomlinson.

SELLING CLASS (Any variety).—1, W. Besver. 2, W. Barfoot. *c*, J. Spence. H. Yardley.

CAGE BIRDS.

CANARIES.—*Yellow or Buff Norwich* (Clear).—1 and 2, W. J. Toon, Kettering. *hc*, Cleaver & Johnson, Kettering. *Yellow or Buff Norwich* (Variegated).—1, 2, and *c*, W. J. Toon.

LINNET, GOLDFINCH, OR OTHER ENGLISH FINCH.—1, Cleaver & Johnson, Kettering. 2, Mrs. Wallis, Kettering.

PARROT (or other large Foreign Bird).—1, G. Pell, Kettering (Grey Parrot). Extra 1, W. King, Wellingborough (Yellow Macaw). 2, Mrs. Salmon, Kettering (Grey Parrot).

SMALL FOREIGN CAGE BIRDS.—1 and 2, Mrs. Wallis (Bishop Birds and Zebra Waxbills. *hc*, Mrs. Wallis (Weavers, Java Sparrows, and African Waxbills); J. Oakley (Budgregsrs).

RABBITS.—*Heariest.*—1, J. Wilson, Kettering. 2, No competition. *Lop-eared.*—1, Cleaver & Johnson, 2, No competitioo. *Fancy Variety.*—1, W. Flavell, jun., Kettering. 2, J. Roe, Thorpe Malsor.

The Judge was Edward Hewitt, Esq., of Sparkbrook, Birmingham.

SNAITH POULTRY SHOW.

THE Snaith Agricultural Society's Exhibition was held in Mrs. Shearburn's Park on the 1st inst. The Show of Poultry, Pigeons, Rabbits, and Cage birds in connection with this meeting was of a respectable character, and many of the best birds that could be found were brought forward, and those calling for especial notice were a pen of Brown Red Game in the class for "Any variety," and which were awarded what may be termed the champion prize; a Partridge Cochin cock shown by Mr. White; and the single Game cock from Mr. Brierley.

In *Pigeons*, Mr. Thompson's Carriers were good. Messrs. Newbitt may well be proud of the Yellow Turbits to which was awarded the medal for the best pair of Pigeons.

Rabbits were but moderate; but the *Canaries*, mostly of the common Yorkshire variety, were very neat, while the Goldfinches were as good specimens of the English variety as can be seen. The following is the prize list:—

ANY BREED.—1, E. Ackroyd, Bradford. 2 and *hc*, Messrs. Newbitt, Epworth. *c*, F. Sales, Crowle; R. W. Richardson, Meanx Abbey; Rev. G. Hustler, Stillingfleet Vicarage; C. W. Brierley, Manchester. *Cock.*—1, J. White, Netherton. 2, C. W. Brierley. *hc*, F. Sales, Crowle; W. A. Taylor, Manchester; E. Ackroyd, Bradford.

GAME.—1, J. Fletcher, Goole. 2, F. Sale, Crowle. *hc*, C. W. Brierley.

RAMBUNOUS (Golden).—1, J. Rawlinson. 2, G. Holmes. *hc*, S. & R. Ashton.

HAMBURGHS (Silver).—1, G. Holmes.

SPANISH (Black).—1, Messrs. Newbitt. 2, G. Holmes.

DORKINGS.—1, G. Holmes. 2, J. F. Beaumont, Huddersfield. *c*, Rev. G. Hustler.

COCHIN-CHINA.—1 and 2, W. A. Taylor. *hc*, C. W. Brierley.

SELLING CLASS.—1, F. Sales. 2, Messrs. Newbitt. *hc*, S. & R. Ashton. *c*, J. F. Beaumont; J. B. Hepworth.

BANTAMS.—1, C. W. Brierley. 2, S. & R. Ashton. *rhc*, Bellingham and Gill *hc*, G. Holmes. *c*, T. Eggleston.

GUINEA FOWLS.—1, H. Merrikin, Driffield. 2, Mrs. Bradley. *hc*, J. Ingle, jun.

GEESE.—1, J. White, Netherton. 2, Rev. G. Hustler. *hc*, W. White, Crowtrees.

DUCKS.—1, J. White. 2, R. W. Richardson.

PIGEONS.—*Carriers.*—1, R. Fleming. 2, Dr. Thompson, Snaith. *hc*, W. Fowler, Pontefract. *Croppers.*—1, S. Robson, Brotherton. *Tumblers.*—1, J. T. Lishman. 2, Messrs. Newbitt. *hc*, W. Fowler; C. Gravill. *Jacobins.*—1, Messrs. Newbitt. *Fantails.*—1 and 2, Messrs. Newbitt. *hc*, J. Robinson. *c*, J. H. Earnshaw. *Any Breed.*—1 and Medal, Messrs. Newbitt. 2, T. Eggleston, Halifax. *hc*, R. Siddall; R. T. Lishman; W. Fowler; S. Robson. *Selling Class.*—1, R. T. Lishman. 2, S. Robson. *hc*, R. Siddall; S. Newbitt. *c*, R. Siddal.

CAGE BIRDS.—*Canary.*—1, F. Higgins, Pontefract. 2, — Wells, Hadfield. *hc*, G. Briggs, Goole. *c*, — Wells. *Red Cap.*—1, G. Trimmingham. Extra 1, H. Holmes, Cowick. 2, C. Gravill. *c*, F. Higgins.

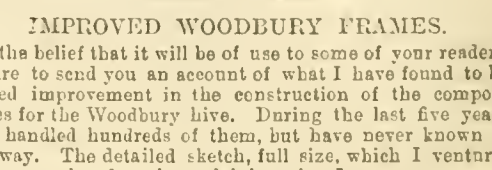
RABBITS.—*Buck.*—1 and 2, C. Gravill, Thorne. *Doe.*—2, J. W. Carr, Topham.

JUDGE.—Mr. E. Hutton, Pudsey, Leeds.

IMPROVED WOODBURY FRAMES.

IN the belief that it will be of use to some of your readers, I venture to send you an account of what I have found to be a decided improvement in the construction of the compound frames for the Woodbury hive. During the last five years I have handled hundreds of them, but have never known one give way. The detailed sketch, full size, which I venture to enclose may be of use in explaining what I mean.

Mr. Woodbury directs "a three-eighth rabbet to be cut out of



the top inner edge at the back and front of the hive." This rabbet is omitted altogether, and the notches for the frames sunk nearly three-quarters of an inch deep. Small blocks of wood which exactly fill these notches are then glued and bradded to the frames; but in order to get sufficient bearing surface for this, the sides of the frames are made a quarter of an inch longer. It will be seen from the sketch that when the bar is in position it will have the appearance of being sunk, but the space available for comb-building is in no way altered.

Advantages:—An increase of strength where the frame was decidedly weakest, increased surface for the fingers and thumb to lay hold of in handling; greater steadiness, and this more especially when the cover is screwed down, since it presses on the tops of the blocks, so that if the hive were turned upside down, the frames could not move.—E. B., *Broughton Vicarage.*

UNITING LIGURIANS.

A STOCK of Ligurian bees in a straw hive threw a swarm on Sunday last; they have refused to work in a super, and the old queen leading the swarm was one I had from Mr. Woodbury four years since, and could not fly, so the swarm returned; however, I secured her majesty, and placed her with a few of her own subjects in a bell-glass partly filled with worker and drone comb. If I put the glass on the top of an

empty hive, remove a strong colony of hybrid bees from their stand, and place the one with the old Ligurian queen and the few bees in its place, shall I obtain a strong swarm? or will the hybrids kill the old queen? If so, will she leave brood in the bell-glass for them to rear another queen from?

The stock which swarmed is still very strong, the bees having returned, but they refuse to enter the super, and I can hear what I believe to be the young queen almost constantly piping. Is she imprisoned? and if so, how is it she is not released now the old queen is gone?—An Old Subscriber.

[It is much to be feared that the hybrids will kill the old queen, but she may lay eggs in the super. Had you removed her own hive, and allowed her to be joined by the returning bees, success would have been certain. A young queen is, doubtless, at liberty within the hive, and the constant "piping" denotes the probability of her soon leading forth a swarm. You cannot do better than advertise any stocks which you may have to spare.]

FOUL BROOD—ITS PRODUCTION AND CURE.

It may be remembered that in the number of "our Journal" issued on the 11th of March last, I noticed a new theory by Mr. Lambrecht, of Bornum, in Prussia, on the subject of foul brood. I have just received a communication from that gentleman, of which the subjoined is a translation, and by which it will be perceived that his alleged discovery is in course of investigation by a committee of German bee-keepers, who are satisfied that he has succeeded in producing foul brood in a healthy stock by feeding it with fermenting honey and pollen, and that he has yet to complete his undertaking by curing this virulent disease within two days. Should he succeed in so doing he will deserve to be rewarded for his discovery, and I, for one, shall not grudge the moderate rate of subscription which he requires for divulging it.—A Devonshire Bee-keeper.

ON THE ORIGIN AND CURE OF FOUL BROOD.

For some years I have busied myself with endeavouring to discover the origin of the deadly plague of foul brood, and having by the aid of chemistry and physiology, after numberless experiments, arrived at certainty on this point, the natural result was the discovery of means whereby in the shortest period the causes and their disastrous effects can be removed. About a year since, I ascertained that the first cause lay in fermenting pollen, by which foul brood is produced, and my apiarian friends then urged me to publish this discovery, certainly not an unimportant one for the science of apiculture, in an article of some length, under the title "Foul Brood amongst Bees: its Origin, and the Means whereby it may with certainty be removed." [Extracts containing the substance of this article were published in The Journal of Horticulture of the 11th March last.] After I had thus settled the foul-brood question, and had discovered as possible causes of the pestilence, besides fermenting pollen—feeding with flour or meal, with fermenting honey, with honey with which grease is mixed, contagion, and, lastly, spreading the pestilence by suffering substances to decompose near the hives,—various views were expressed in the bee-keeping world, and especially against my theory that fermenting pollen is a cause of foul brood. Consequently I undertook to demonstrate the truth of that theory before a competent commission of apiarians.

Mr. Gravenhorst, a bee-master in Brunswick, placed a strong stock of bees during the course of last spring at my disposal, and I commenced carrying out my experiment on the 1st of April. As I believe that the matter will be interesting to the intelligent apiarian, while a cure for foul brood will be welcome and satisfactory to all, I subjoin a copy of the reports of the commission.

First Report.

"Brunswick, April 1st, 1869.

"The undersigned certify that the stock given by C. J. H. Gravenhorst for the purpose of experiment, was found upon thorough investigation to be perfectly healthy, with brood in all stages, and sufficiently populous. A. Lambrecht, in our presence, inserted a comb containing pollen and honey in a state of fermentation within the hive near the brood. The care of the stock was entrusted to Mr. Gravenhorst, who reserved the right of placing it at a distance of two miles from his own stand.

(Signed)—C. J. H. Gravenhorst,
Heinrich Oppermann,
H. Herbst,
H. Wiedewroth."

Second Report.

"Brunswick, April 24th, 1869.

"The persons mentioned in the former report went this day, together with Mr. Lambrecht, to the place where the experimental hive was standing. After examining it, Mr. Lambrecht pronounced the colony to be in the early stage of foul brood. Although there were single larvæ or nymphæ dead and in a suspicious state, yet the opinions of the Committee were divided at to the presence of foul brood. This induced Mr. Lambrecht to give the bees a further portion of fermenting pollen with honey, and to demand that two frames of comb some years old should be inserted. Mr. Gravenhorst was charged with effecting this as soon as possible."

(Signed as before.)

Third Report.

"Brunswick, May 23rd, 1869.

"The undersigned inspected the experimental hive this day. In both pieces of old comb, inserted on May 2nd, they found cells pierced and unpierced with depressed covers, from which, after tearing them open, a sticky, fetid, brownish grey substance was extracted. The Commission decided and expressed their full conviction that foul brood had broken out, especially as decaying larvæ were found also in newly-built drone combs."

(Signed as before.)

Science has solved a difficult problem; the causes of foul brood are made plain, and are known; it has, therefore, become possible to discover means, by the application of which foul brood can be cured in one, or at most in two days, and the fermented vitiated honey again made fit for bees.

The means and the process of cure will be published in the course of this year in a pamphlet, for which purpose a subscription list is opened. Should five hundred subscribers give in their names, the price of a copy will be 4 thalers, Prussian currency (12s.). Names and addresses may be sent to Mr. Gravenhorst, in Brunswick.—A. Lambrecht, *Bornum, near Börssum, Brunswick.*

FAILURES IN BEE-KEEPING—SWARMING versus SUPERING.

Having seen at various times in your valuable publication some accounts and also advice on bee-keeping, I make bold to ask a little advice of some of your amateur correspondents, not only for myself but also for many others, who I presume are in about the same difficulty as myself. Too many of my old stocks are very weak, and no doubt those of many others are the same. I have kept bees for some years on the old or swarming system, and also by taking the honey from the top of the hive in supers, not allowing the bees to swarm. I believe my situation is not a very good one; but be that as it may, the swarming system does not answer so well as it ought, for after swarming the old stock is too often so much reduced as to be unable to recover sufficient strength to encounter the ensuing winter, and consequently the bees die before spring.

On the super system also, in too many cases after a couple of seasons, the bees dwindle away, and in the third year do very little or no work, unless (by means that we know nothing of) they have their old queen replaced. I have bought both swarms and casts, and I invariably find that the casts do the best, if they come in time to collect sufficient to carry them through the winter. Therefore I am obliged to believe it must be a young queen that goes out with the cast. Indeed, I cannot see how it can be otherwise. If the old queens do not go out with the swarms, I am almost sure they do not go out with the casts.

Now it appears to me, that the non-swarming system requires young queens about every two years to do well. Therefore, if any of your bee-keeping correspondents are of the same opinion, will one of them be kind enough to tell me the best way, and with least trouble, to obtain a succession of young queens at least every alternate year?—A Kent Bee-keeper.

[We shall be glad of the opinions of any of our correspondents who may be able to explain the probable causes of failure.—Eds.]

DISLODGING BEES FROM A TREE.

Three years ago a swarm of bees went into a large tree just outside our gate. They cast a natural swarm two years ago; last year they contented themselves with increasing their own colony; this year they are very numerous and strong, and have seemed ready to throw off a swarm for a fortnight, but have not yet done so. These are their doings, now for a brief account of my doings.

A fortnight ago—having previously purchased the tree, I had it cut down the trunk, taking 2 or 3 inches off the two highest pieces of comb inside the tree, thus making sure that I had reached the colonists. On this stump, now 4 feet in height and 2 feet in diameter where cut, I placed a common straw skep, with the entrance of course facing the south, their old and what is still their present entrance being on the ground at the very bottom of the trunk, facing the north-west. A landing board was fixed on the top of this stump opposite the entrance to the straw hive, now secured and properly protected. The entrance to the straw hive I kept completely closed for four or five days; I then opened it, expecting that the bees might abandon their former lowly entrance and go out and in from the top, and ultimately fill the straw hive with combs, &c.; and when her majesty should be there rejoicing in the ample dome (to her) so mysteriously placed on the apex of her old abode, I would remove the skep with a tremendously strong swarm, or rather colony of bees, at some convenient season to my apiary at the garden top. These bright anticipations, or rather hopes, have not and do not seem likely to be realised, for not a bee availed itself of this new entrance either in going in or coming out by it. And they did not seem to be working in the skep at all, so I again closed and completely darkened the entrance to the hive, and they are still going on as if the tree had never been touched.

This is what I have done. Now, what I want is to get the bees out of that old tree stump into a hive, so that I may gradually remove them to my apiary, and take the honey out of the tree, quietly and unmolested by its present inmates, for my trouble. How am I to proceed in order to accomplish this? This is my only question, and I hope you will be able to give me an answer as soon as possible, as I would like them properly housed in good time to provide for themselves during the coming winter.

I could drum, or "drive" as you call it, a swarm out of a hive full of combs, &c., and place that on the top of the stump, and close up their entrance hole at the bottom, if you thought that would do any good.—Old Tree Stump.

[If the bees had taken possession of the empty hive it would only have been by way of super, and the seat of breeding would have remained in the tree stump or "Ktotz hive" as it is styled by the Germans. The same result would probably ensue, even if you placed a full hive on the top. If you must get them out, we see nothing for it but to attack them *vi et armis* by cutting the stump to pieces, excising the combs, and fitting them into a frame hive, into which the bees must then be swept; but this is rather a formidable operation for which no specific directions can be given, and which ought only to be attempted by a skilled apiarian.]

BRITTANY COWS.

In answer to your correspondent's inquiry respecting Brittany cows, I can inform him that, having kept them for many years, I have found them very satisfactory. They are hardy, and do well on poor land, and in winter they do not require so much feeding-up as other breeds, especially the Alderneys. They are far hardier than the latter, and though I do not think their milk so rich or good for making butter, they give in proportion to their size a considerable quantity. One of mine yielded eleven quarts daily at her best time. This of course would be considerably above the average, although I have one at the present time which gives nearly the same quantity. I believe them to be proof against the cattle disease, having never heard of an instance to the contrary, and having known a case in which Brittany cows running with Alderneys escaped, while the latter took the disease. They are said to fatten well, and make good meat.

There are, I believe, two distinct breeds imported, one larger than the other, and this would be the more profitable for your correspondent to try. I have brought them of Mr. Baker, of Fulham, and more recently from Messrs. Robertson, 113, Leadenhall Street, London. Black and white is the common colour, but some are red and white. They are extremely docile, and will bear being tethered where they cannot have their liberty. The one difficulty is with regard to the bull; and "Subscriber" would be wise, if he intends keeping them, and there is not a very small bull of some other breed in the neighbourhood, to keep a Brittany bull.

I have replied at some length, as I think your correspondent will like to have the personal experience of one who has kept the breed.—John Pares.

OUR LETTER BOX.

Thorne Poultry Show.—A correspondent writes that the second prize for a single buck Rabbit was awarded to Mr. C. Gravil, jun., of Thorne. We gave the prize list as we received it.

Colchester Poultry Show.—"In your Journal of the 27th ult., in your remarks upon the Colchester Poultry Show, you say you mistake not if you had seen the birds that took the first and cup in the Dorking class in a selling class, because his feet were bad. I should feel obliged if you would contradict this statement; I bred him myself, and he has never been exhibited before.—W. Tippler."

Rice and Wheat as Food for Poultry (*Young Beginner*).—Rice, either raw or cooked, unless boiled in milk or gravy, is the most wasteful, unprofitable, unsatisfying, and wretched food you can give. It produces the symptoms you name, and, in addition, covers the body of the fowls obliged to feed on it with parasites, which literally tease and worry them to death. We class rice for poultry and sawdust for human beings in the same category, so far as nourishment is concerned. We tried it many years ago on pigs, Geese, Ducks, and fowls; all fared alike, and we buried most of them. The survivors, those that lived in spite of the rice, never throve afterwards, but seemed to have the same brown, shrivelled skin native Indian artists give to their brethren who feed on the same food. Wheat is not injurious to fowls, but it is inferior as food to barley. April pullets kept in confinement will not lay before December. They would lay earlier if they had their liberty. The Brahmas will probably lay first.

Exhibiting Brown Red Bantams (*J. L. D.*).—We cannot be so invidious as to classify them as you request, but any of the following twelve shows will be found among the most prominent of our meetings, and we feel assured will sufficiently test the good qualities of your birds to win at either of them. They are jotted down promiscuously:—Whitehaven, Kendal, Jedburgh, Hull, Bath and West of England Society, Beverley, Middleton, Halifax, Manchester, Birmingham, Ipswich, Southampton.

Rearing Turkeys (*J. P.*).—If, when you asked our advice, you had told us you intended to rear Turkeys on a small space, we should have advised you not to attempt it. They bear confinement badly, and the proof is, that yours are suffering. They inflate the skin of the lower beak and of the cheek because their nostrils are stopped up, and not as though they were. The sooner you can give them the run, the sooner they will recover. There is virtue in the smell of new-mown grass; and in the present state of the heads of your Turkeys, if you could induce a moderate attack of "hay fever," it might be beneficial. Wash their nostrils with cold water and vinegar, give them one, or in bad cases, if the bird is not too weak, two pills of camphor the size of a garden pea. Let them have no drink but ale. They will soon like it, and from the time they have acquired the taste, they will eschew water. It will not, however, be wise to give them all the liberty the fresh-mown space affords. Turkey poults are very mother-sick, and a hen Turkey will wander through the dewy grass at early dawn, starting with her thirteen "olive branches." They will perish at the rate of two every hour till the sun is up, and she will return full and triumphant; she will "rest and be thankful" while three or four remain. She does not make troubles. Confine her under her rip in the sunniest spot you can choose. Do not give her her liberty till the sun is up, and the grass is dry. Use oat, pea, barley, and bean meal mixed, and add to it, when slaking with milk or water, lots of onion-tops chopped fine.

Uniting Bees (*M. J. P.*).—Drive the inhabitants of both stocks into the same empty hive, then knock the whole out upon a cloth spread on the ground, and place the full hive over them supported on two sticks to avoid crushing the bees, which will speedily ascend without fighting.

Honey Tasting of Vanilla (*A. B.*).—There is an infinite variety in the flavour of honey, and that collected from lime tree blossoms has a peculiar taste, which, if you are not acquainted with it, may possibly have been mistaken for vanilla.

Swarm Returning to the Hive (*J. V.*).—The queen may not have accompanied the swarm, or she may have dropped on the ground and been lost. In either case it is likely that the swarm will again come forth.

Food for a Cuckoo (*M. M., York*).—Soaked bread and bruised hempseed mixed with it, and hard-boiled egg; but its principal food should consist of raw beef cut small, meal worms, garden worms, caterpillars, and occasionally a snail.

Food for a Blackbird (*V. E.*).—Bread soaked in cold water and squeezed every day, and bruised hempseed mixed with it, may be the usual food; occasionally a little hard-boiled egg, potato and carrot may be added for a change. About twice or three times a-week it should have three or four meal worms, or garden worms, or a little chopped meat, beef being best. Water should be given at once, and always supplied. The bird is very fond of fruit any way.

Food for a Young Owl (*Idem*).—Soaked bread, chopped egg, and scraped meat, scraped or cut up very small, mixed together; the meat should be in the larger proportion. When it can feed alone, meat should be its principal food. The evening is the most suitable time for feeding.

Bottling Gooseberries and Rhubarb Green (*Fruit*).—When the gooseberries are a little more than half grown they must be gathered dry, and after being picked clean put into wide-mouthed bottles, shaking them gently down till each bottle is full. Cork the bottles tightly, set them in a moderate oven, and let them remain till heated through. Beat the corks in tightly, cut off the tops, resin them over, and keep them in a dry, cool place. Cut and peel the rhubarb as for tarts, put it in clean dry bottles, cork them, but not tightly, put them in a pan of cold water, and set them on a moderate fire. When the rhubarb changes colour, and begins to shrink a little in the bottles, take them off the fire, and let them stand till cold; then cork them tightly, and set them in a cool dry place, with the necks downwards, to prevent the rhubarb fermenting. Be careful the oven is not too hot, or the bottles will fly. Cork them tightly when they are quite cold. It is a very good plan to lay a double sheet of brown paper in the oven, and place the bottles on their sides, turning them occasionally.

WEEKLY CALENDAR.

Day of Month	Day of Week.	JULY 15—21, 1869.	Average Temperature near London. Day.	Night.	Mean.	Rain in last 42 years.	Sun Rises.	Sun Sets.	Moon Rises.	Moon Sets.	Moon's Age.	Clock before Sun.	Day of Year.

From observations taken near London during the last forty-two years, the average day temperature of the week is 74.5°; and its night temperature 50.3°. The greatest heat was 94°, on the 17th, 1834; and the lowest cold 37°, on the 18th, 1863. The greatest fall of rain was 1.60 inch.

EARLY PEACHES IN ORCHARD HOUSES.

IT is now generally agreed that our fruit crop of all kinds on the open walls will be small, however brilliant may be the exceptions. Many reasons are urged for this, the chief and most probable of which seems to be the disastrous spring weather during the blossoming period, which rendered profitless those summer shoots which the unusually warm season of last year had ripened. No doubt, however, in light soils, where the aid of hand-watering was not available, even these shoots were somewhat dried up, and will now recover a little, but more than all by a temporary absence of production.

If we bear in mind that nothing exhausts a bearing tree so much as excessive cropping, which exhaustion no artificial stimulants will long correct, we may reach the true reason of many cases of failure this year, especially under glass. Orchard houses are now very common, and the knowledge required to work them fairly is nearly as general, but whether it be over-confidence in the powers of trees, simply because they are in glazed structures, the unreasonable demands of ignorant owners, or that there is yet something to be learnt from the greater experience of others, I may, with confidence, here point out such a certain cause as excessive cropping as one great reason of this season's shortcomings. My experience, as one of the very earliest orchard-house cultivators, decidedly points to this fact, and I have always so carefully regulated the amount left on each tree as to insure a good crop, no matter what the season has been, and this without any aid from hot-water pipes. These would be, however, extremely useful as auxiliaries in almost every instance during such a spring as we have passed through, for the blooming process was performed under very unpropitious conditions everywhere. Here the drenching cold rains filled the houses with stagnant vapour, which the absence of wind prevented our keeping in motion so as to keep the pollen from being glued in. We did not know what to do. If we opened the ventilators, we lowered the already-diminished temperature; if they remained closed, the evil became greater from stagnation. A little artificial heat then would have enabled us to stir up and move the clammy mist, and by admitting top air, to completely renew the atmosphere at our will. Since that period we have had here only partial gleams of sunshine, which often disappeared in damp sea haze, making the very walls of passages white with drops of vapour. What can be hoped for under such conditions, without some artificial appliances and much extra trimming and adjusting?

Nevertheless I am quite sure had not the crop upon my trees been year after year carefully thinned, and less fruit left on them each season than we hear of so often in these and other columns, that nothing would have availed to make a fair amount set. The trees have been regulated every year according to their powers of bearing, and have now acquired a steady habit of production. Thus they are independent of atmospheric changes; nay, expecting that the crop would be short by reason of our early spring weather, I have, from motives of profit, actually called on these obedient cordons to repay me some portion of my time and money spent on them, and have now ripening the largest crop of Peaches and Nectarines that has been borne in these houses for fifteen years. Some diagonal cordons of this mature age are now covered so thickly with fruit as to be a wonderful sight; let us hope they will not suffer too much from this unreasonable demand. When first these diagonals were introduced, it was objected to them that they would soon be worn out. On the contrary, I think it is certain that no trees in pots—much less trained fanwise—could have thus kept up their rate of production for a succession of seasons, and in a year like the present, when the best growers own to a "short crop," supply an extraordinary demand on their vital powers. The cordons have much the best of it in 1869.

It requires no great amount of skill to obtain a heavy crop from potted trees, received from good nurseries in splendid health and vigour, but how long will the same trees continue to bear at this rate? Do we not hear soon of attacks of red spider, of weak buds, and of fruit dropping when stoning? There remains a consolation, and that is, that these trees may bear well next season, simply because they have had an enforced rest. To obtain regular crops, which shall be heavy and well ripened, we must have an extra supply of trees, and allow some of them to rest every third year or so; and this is very easy and inexpensive to do.

The blooming process is exhausting to trees. It is, in fact, more like an act of abdication than of progress. The tree has to reproduce its kind, and make room for another generation. The great heat of last season had probably filled the cellular tissues with an abundance of "reserved sap," and thus prepared an early and free bloom. With us this occurred rather earlier than common, and lasted an unusual length of time. There was also plenty of bloom on the trees, but fearful weather. In the case of trees under glass, now was evidently the time to try my old friend Grin's "last dodge"—to mutilate the flower buds while still in embryo! But alas! my faith was too weak. I recognised the correctness of the principle, but had neither the skill of manipulation required for such a delicate process, nor the power of sight. M. Grin must use glasses of strong magnifying powers: nevertheless he is right, as such a skilful cultivator should be, and we might with advantage thin-out the excess of bloom on our trees—under glass at least. In the open air, except in the case of vigorous Pear and Apple trees, it would be full of risk in uncertain weather. By leaving only the central bloom bud of each cluster of Chaumontel Pears, which set freely, we may calculate on producing those longer-shaped fruits which are most admired, and weigh so much. But I confess to not having practised this thinning of the bloom of Peaches under glass, preferring to reduce the amount as soon as the blossom had set, and to do so with an unsparing hand, and the result has been good.

The Peach crop on the open wall must be a failure in general, and I have heard on the best authority that it is

so likewise on the Continent. Around me there is little or no fruit, and on my close-pruned out-door trees about one-fifth of the usual amount only. Plums are a failure, Apples moderate in number, but Pears show fairly. The cordons are here well stocked. It is amusing to see a large Jefferson Plum tree, fan-trained, without a single fruit, while some ten diagonal Pear cordons of, the very newest kinds, from Mr. Rivers, and occupying about the same wall space near it, are in free bearing, being young, and strictly thinned.

But all this while I am forgetting my usual report on the earliest Peaches in orchard houses.

Notwithstanding the absence of the sun's rays, the fruit is ripening well, and the colour is good. The first Peach which ripened was Early Beatrice (Rivers), and this actually was gathered on the 12th of June, well coloured, but not so large as I should desire; still it is the earliest Peach I have ever gathered, grown as a diagonal cordon on the wall.

The next to ripen was Early Rivers, also on a cordon, and this was perfectly ripe by the 1st of July, and fit to take even earlier. In size all the Peaches of this kind were remarkably even, and all about 8½ inches in diameter. The ground colour of this beautiful Peach is a fine greenish yellow, mottled on the sunny side. The shape is roundish, the flavour pungent and "peachy," and the juice abundant. It is the finest early Peach I have ever seen, and will soon advance to being here a regular June Peach. I should prefer it to Early Beatrice, and shall cultivate it largely. It is here from eight to ten days earlier than Early York, and larger than it this year. Mr. Rivers has other kinds, he tells me, as good, if not earlier, and if so, I congratulate orchard-house growers, for it is very early Peaches which we most require.

The next Peach which ripened was Early Victoria, a kind I had not before quite liked, but this year it is extremely good, well coloured, and of excellent quality. Early York is coming in fast also, and to-day we gather the first regular supply.

This season, therefore, is in nowise backward in its results; so far, I think, on the whole, that Peach-growers will not be disappointed, but that as the summer proceeds they will find their crops ripen and colour fairly. We know very little about the rays which give colour to fruit, but certainly a white sky which fatigues the eyes to stare at is very favourable, even more so than a space of unclouded blue. As I said before, Nature having taken the regulation of the crops this year in hand, no doubt there will be a better season in 1870.

Now is the time to try the close pruning of the summer shoots; they grow rapidly this year, and an excess of wood will only augment October regulation, and half of the wood will be unfit to bear fruit. If the Peach shoots have been stopped to four leaves, then the second growths should be restrained to one or two more. Already we should decide on the shoot intended to be the new fruit-bearer and that which shall be reserved for succession, and be cut back in October. No good pruner likes to make the same shoot the fruit-bearer and the shoot-bearer also, but prefers to have them alternately so occupied; but in this case he will not allow either to extend beyond what will ripen fairly. In this way the "alternate system" of pruning is properly carried out.

I had forgotten to say that a new seedling Peach, No. 22 (Rivers), has just been gathered here of a good size, well coloured, and very early also; but my favourite is Early Rivers. —T. Bréhaut, *Richmond House, Guernsey.*

CENTAUREA CANDIDISSIMA CULTURE.

To few plants has a greater share of attention been given, so far as regards the correct method of its propagation, than to Centaurea candidissima; whilst as usual, when there is a somewhat difficult subject, many different modes have been advanced, all of them more or less meritorious; but, as is generally the case in such instances, the simplest method proves to be the best. "A rum un to strike," observed an acquaintance to me. "Why so?" said I. "Don't know," was the very laconic but unsatisfactory reply; and then came the additional information that "the thing would do nothing but damp-off, no matter how much it was coddled." Oh! this coddling system has caused the death of many a promising batch of other things besides the Centaurea. Well, I confess that I adopted the coddling system myself with the first considerable batch of cuttings of this plant that came into my hands. It happened thus: A gentleman who was the fortunate possessor of a fine stock of this plant, when it was scarcer than it now is, offered me a quantity of cuttings late in the autumn. Although doubtful of my chances of success, I could not resist the offer, and accordingly the cuttings were inserted with the greatest possible care, and the pots were plunged in a brisk bottom heat, when, although every care was exercised in watering, not one cutting survived. On the giver of the cuttings inquiring some time afterwards how I had succeeded, I could not help thinking that his countenance wore a smile of rather malicious enjoyment at the account of my failure. However, an occasional failure, if acting properly on the mind, is but an incentive to increased exertion, and not unfrequently leads to success.

If rightly understood, the propagation of the Centaurea is very simple, and by following a few easy rules, it may be practised with the greatest certainty of success in July and August, as well as early in spring. I shall not dwell upon its propagation at the latter period, as it then strikes as readily as most other plants if the cuttings are placed in a genial, moist temperature, but will only note an erroneous statement, that spring-struck cuttings form the best plants for the ensuing season. My own experience is directly opposed to this, for although glad to propagate it in spring when working up my stock, yet I have never found the strongest spring plants equal in vigour to those propagated in the preceding summer. The method, then, which I practise, is to take cuttings as early as possible in July, and firmly insert each in a thumb pot, with soil consisting of loam, leaf mould, and sand, in equal proportions. Care should be taken to leave an ample depth from the soil to the rim of the pot, to contain water to moisten the whole of the soil when necessary. The cuttings are then placed in a greenhouse, where they enjoy an equable temperature of about 70°, often much hotter in bright days, and are partly shaded by the foliage of some pot Vines, but no regular shading is used, neither is air withheld. The two chief points to observe are care in watering, and a temperature not averaging much below 70°. It is of the greatest importance that the cuttings should be firmly fixed in the soil; a short stick of the same size as the stem of the cutting, tied to it before it is put in, is of great assistance in keeping it steady. By using these sticks, more of the heavy leaves can be retained on the cutting.

When roots are formed the young plants are at once removed into the open air, where they remain till housed with the general bedding stock. A second lot of cuttings is taken off in August with equal success. I am aware it may be urged that July is somewhat early to make cuttings, but in ordinary seasons, if the plants are as vigorous as they ought to be at the time of planting, good side shoots will be formed by the second or third week in the month. The present backward season will, I fear, form an exception, and consequently it would undoubtedly be an excellent plan to retain a few plants in a spare border specially for propagating from; or, better still, if the plant is really hardy, to establish a few permanent plants entirely for a supply of cuttings. A large plant growing here has passed through two winters unscathed, and apparently with increased vigour; it now measures nearly a yard in diameter.

The hardiness of this plant adds to its value. I this year turned the whole of my stock into the open air on the 31st of March, placing a double line of the plants close to the front wall of some pits, but with no other shelter, and as there was a considerable number of them, the space under glass gained by their removal was very valuable. The free growth and elegant proportions of Centaurea candidissima, together with its peculiarly distinct soft grey colour, have justly given it a leading position amongst ornamental-foliaged plants in the flower garden, and if used with judgment, no plant tends more to enliven a design; but its bold appearance also causes it to be a somewhat dangerous plant to use; for a flower garden containing a preponderance of light colours is quite certain to appear so insipid as to afford very little pleasure to the beholders.—Edward Luckhurst, *Egerton House Gardens, Kent.*

VICOMTESSE HÉRICART DE THURY STRAWBERRY.

Having grown this Strawberry for some years, I can fully endorse all "Archambaud" has said in its favour. It is, without doubt, one of the most useful Strawberries we have in cultivation. For preserving, the Vicomtesse Héricart de Thury Strawberry is a great acquisition, both as regards its flavour and its beautiful colour—a quality of no small importance.

If this Strawberry were better known, I may venture to say that it would be largely grown.—J. GARDNER, *Elsham Hall Gardens, Brigg.*

EAST LOTHIAN STOCKS.

HAVING been to some considerable extent the means of spreading the fame of these Stocks beyond the locality where they have been so largely cultivated, I felt very sorry lately to see them depreciated by writers in your columns; not that their excellence as cultivated and described by me and others in the far-famed Lothians of Scotland can be gainsaid by anyone, but because I regarded it as a pity that such splendid decorative plants should have disappointed any one in other localities. Being convinced of their value, I resolved to grow them largely at this place, and planted them more extensively than ever they were planted at any place before; and I am happy to say that in a totally different soil and somewhat different climate, they are more than equal to anything I ever saw in the Lothians of Scotland at this date. The plants are unique in habit, and while the majority are coming into bloom, I have not yet seen a single flower amongst them, and I have no doubt they will in this respect be equal to anything I have previously said of them—namely, have 80 per cent. double. These will last in beautiful bloom till winter, and, if the plants be lifted and taken care of, they will bloom all next summer.

No wonder they have not succeeded in some places if reared and treated as Stocks generally are treated—viz., sown in a bed or pans, never pricked off, and planted out weak and spindling. Let any other bedding plant be so treated, and what would be the result? Many other plants now neglected would, by careful cultivation, become so changed and improved as to be scarcely recognised as the same.

Doubtless some may have been disappointed and deceived in obtaining the true varieties of these Stocks when applying to seedsmen. This should make them more careful in future; still, I am certain the starvation system of cultivating has much to do with the character they assume. I have always bestowed great care in rearing these Stocks, and the results have always been such as more than justified such a course and what has been said in their praise.

Mr. Lees, of Tynninghame, last year proved conclusively that cultivation had an influence on the amount of double and single blooms produced. He planted a certain number of plants from the same sowing in poor dry soil, and some in rich soil; the former were nearly all single, the latter nearly all double.

If, instead of sowing thickly in a box or frame and allowing the plants to become drawn and spindling, and then to plant out in carelessly prepared soil, they were sown thinly in February, then potted-off singly in 3-inch pots, and planted-out in the end of April or early in May in well-prepared and rich soil, we should hear less of their lateness of blooming and of single blooms. This is a very late season, yet these Stocks will be fine here this month, and few if any flowering plants stand all sorts of weather so well. Few, if any, plants are so well worthy of extra trouble, whether they be grown in the parterre, in the mixed border, in nursery beds for cutting from, or in pots.—D. THOMSON, *Drumlanrig Gardens.*

TACSONIA VAN-VOLXEMI CULTURE.

MY experience of this magnificent climbing plant commenced a very short time after its introduction to this country, which took place only a few years ago. Being about that time in want of a good selection of climbers for the conservatory, I purchased it solely from the figure and description given in the "Florist and Pomologist," and ever since it has been an object of much interest and pleasure to all concerned. Although this class of plants contains some subjects of unquestionable beauty, for instance, the gorgeous Tacsonia ignea and mollissima, yet I am of opinion that T. Van-Volxemi is unsurpassed—I may say unequalled—by any of them. It possesses extraordinary vigour, is very free blooming, and thrives most admirably in a greenhouse temperature. The flowers are from 3 to 4 inches in diameter, their colour scarlet, and the stamens and pistil stand out conspicuously, and are very ornamental. The flowers are suspended from a green string-like stem, from 1 foot to 18 inches in length, and nearly every flower produces a fruit which grows to the length of from 4 to 6 inches, measuring 1½ inch in diameter at the middle, but tapering equally to both ends.

From the foregoing description, which is not at all overdrawn, Tacsonia Van-Volxemi will be recognised as a most desirable plant for anyone who has a suitable house where it may be grown and trained so as to display its decorative qualities to the best advantage. From the plant's peculiar habit of flowering, it should be grown where the flowers can hang downwards overhead, and be quite clear of the foliage. Walls are objectionable, but porches and the cross bars and roofs of houses are more suitable. Of these positions the latter is preferable, because if the shoots, which will bear training within 4 inches of the glass, are about 6 inches apart, every flower will be so placed that its beauty can be seen to great advantage. The plant growing here is situated at the principal entrance to the conservatory, which is a kind of projection from the main roof. It covers the whole of this small roof, and forms a most agreeable shade to plants beneath it; its roots are in a bed of soil 10 feet long, 4 feet wide, and 4 in depth, under the flagstones at the entrance. This bed has plenty of drainage, and is quite independent of the larger beds in the conservatory. The soil is made up of one-half rather heavy turfy loam, and one-half leaf soil, mortar rubbish, and sand in equal portions. The plant is supplied with plenty of moisture when growing, and its pruning, up to the present time, has been confined to thinning and shortening the shoots which have gone beyond bounds. I am ripening the wood just now in order to give the plant a thorough pruning before starting it into growth for flowering during winter, which it did last winter most profusely. The plant appears to be less liable to the attacks of insects and other pests than most climbers, for when others have had them this plant has been quite free, owing, as I presume, to the hard texture of the foliage.—THOMAS RECORD, *Hawkhurst.*

POTATO FAILURES.

I FOR some time hoped that the stubbornness of the early Potatoes in breaking through the ground was peculiar to this district. I find it is not so. Mr. Record in page 368, and "H. H." in page 388, of the last volume, both state their failures and experiences. Information from other sources also brings me the assurance that the failure is by no means confined to any particular locality, but, on the contrary, the complaint is general.

It is very difficult to assign a cause for the misfortune. If, as some think, the failure is owing to the inclement weather which prevailed at and immediately after the time when the sets were planted, it is a cause beyond our power to avert in the future. According to this theory a similar unpropitious spring will bring a similar unfortunate result. Whatever the real cause may be, I am clear that in my case this theory completely breaks down; and I am very sanguine, should the weather early in spring be the same next year as we have recently passed through, that my early Potatoes will break through the ground with the usual regularity. This bold assertion must have a bold backing.

Now for the evidence on the case—stubborn Potatoes *versus* stubborn facts. On the 10th of March I planted a portion of a very warm well-drained south border with Early Ashleaf; on the same day I planted some of the same kind of Potato in an open space—as cold a spot, perhaps, as any in the kitchen garden. Now in the open, and by far the coldest and wettest place, every set grew well—not one failed; while on the warm south border nearly one-half of them did not come up. Some Potatoes from the same batch of seed and planted in a frame, served me the same. Here my experience is different from that of Mr. Record; but perhaps we may find half a reason why his came up as well as usual in frames, and mine did not. Mr. Record's were planted in pits early in December, and all grew; mine were planted in frames in the middle of February—a difference of upwards of two months. This period may only seem of small importance, but it may have had an effect. I have just two more arguments against climatic influences, at least this year, being the cause of the failures. 1st, The finest piece of Ashleafs I have seen this year is in one of the coldest and wettest gardens in this parish; and, 2nd, I planted a few of the same kind in an open place in November merely to see what would be the result, and every set has done its duty well—not one missed, notwithstanding the cold and wet, and they had no protection. Thus, from my own experience and observation, I have arrived at the conclusion that the cause of the failure is the Potatoes themselves being in fault. And why?

I will begin by saying that I believe the theory of the Rev. M. J. Berkeley is sound and is borne out by my practice,

although it is more than a hundred to one that I should ever have thought it out myself. The general crop of early Potatoes was out of the ground two months longer last year than it will be this. If this were a season of rest I do not know that it would so much matter: but it was not so. When a Potato is thoroughly ripened its next mission is to grow again. It will not fail to do this, given a temperature sufficient to rouse it from its slumbers. The extraordinary heat of last summer caused the sap to flow early and continuously, so much so that Mr. Record says the sprouted eyes of his tubers required "rubbing off every week." What a terribly exhausting process! Fancy rubbing off the sprouts every week for four or five months! The Potatoes planted in December had a clear two months' grace over those which had to undergo this exhausting ordeal until they were planted in February. Here, in my opinion, is the point. It is not the long but the short season of rest, and the long season of excitability and purposeless exhaustion, which have crippled their resources. When put in the ground it was their grave, from which they had no strength to rise again.

All this, however, does not so clearly answer the case of "H. H.," who cannot think his Potatoes were exhausted, as he did not rub off any sprouts. Well, this is exactly my case, and, except on the theory of Mr. Berkeley, I cannot account for it. I know they were out of the ground too long, and were over-ripened. I also know in a similar season how I should manage the seed so that it would grow as usual. That the seed Potatoes were too long out of the ground is proved by the fact narrated by Mr. Record, that the Potatoes dug up on the 14th of October and planted in February grew well, while a very large per-centage of those taken up three months previously, failed to appear above ground; and, further, some which I kept back until the end of April for land which was not at liberty before, have nearly all failed to appear. Again, a neighbour, an amateur and very successful Potato-grower, kept his out of the ground, waiting for fine weather, although they never had a sprout rubbed off, and at least 80 per cent. have never made their appearance.

My seed Potatoes were taken up in June, and spread thinly in an airy chamber. They soon commenced to grow, but as they were very thinly spread, and had plenty of light, the eyes did not elongate much. At the commencement of winter I placed them on their ends (this makes them push fewer eyes and much stronger), under the stage of a cool house; they still had plenty of light. Here they produced such sprouts as I never before saw—not more than an inch long, and some fully as thick as a man's finger, and as firmly attached as if they had been glued. I planted them in full confidence that "upwards and onwards" was their certain and unimpeded course towards a fine yield. Now, in planting, some of the very finest were put together in the frame, and marked to note differences of produce. It is these exceptionally fine ones which have not come up. In planting the south border, what I considered the cream of the lot were picked out and put in a few rows by themselves; but the cream became sour—they never came up; while those which had not pushed so strongly, and which were planted in the same border, as well as in the open place before noticed, came up very well. Now, I think, the cause here is clearly over-ripening. On examining those which refused to grow, I found the large stiff sprouts had formed in themselves a Potato of fair size, accompanied by three or four more useless productions.

I think, however, I have stronger evidence that the failures are primarily the result of over-ripening; for some Potatoes which had been kept in a very cool place from the time of taking up—in June, to the season of planting—in March, have come up very well; nothing could have come up better or more freely. I have given considerable attention to this subject; I have examined many plots, and, as far as possible, made myself acquainted with the seed and its manner of keeping, and I find, without exception, that the best pieces are the result of seed which had been kept in the coolest places, such as cellars and the like. I have thus strong grounds for my belief, that if a summer similar to the last occur, providing the seed be kept in a very cool place, it will come up well in the following spring, even if it be as wet and cold as that we have just passed through. I have no experience with the early round Potatoes spoken of by "H. H.;" possibly, as he suggests, they may be more hardy than the Kidneys.

Mr. Record asks if any "great" grower will tell him if the topless progeny are any use. If he will pardon the presumption of a "very little" grower, I will tell him they will, where large enough, make good seed. I once helped to plant a piece of Ashleafs which had been left out of the ground until July; they produced no tops, but some good tubers, which were planted, and turned out quite satisfactorily.—J. W., *Lincoln.*

PYRETHRUM CULTURE.

Double Feverfew being one of the plants mentioned by Abercrombie, may be considered to be an old favourite; and in some gardens it is quite a weed, especially in old ones, where the soil is light and dry. The Pyrethrums of that day, however, consisted of the double white, and a few starry-flowered varieties; but great improvements have been made since then, mainly by Mr. Salter, of Hammersmith. He has converted a nearly flat into a globular form, given us broad in place of narrow florets; in fact, brought them to the florists' standard of excellence—the Ranunculus form. The flowers are larger, of good form and substance, and the colours increased. Every year Mr. Salter sends out many new sorts which are great advances on older varieties, and I hope that he will some day give us a good profuse-blooming yellow, of dwarf habit, that we may be less dependant on the Calceolaria for yellow in our bedding arrangements. A yellow Pyrethrum would be valuable, for in light soils the Calceolaria is of little value in dry summers, but there the Pyrethrum flourishes.

Pyrethrums are not much employed at the present time in flower gardens. They grow too tall, and the flowers produced are not of sufficiently long continuance. In wet seasons, too, they grow too much and flower too little, but the latter drawbacks might be obviated by planting them in lighter and poorer soil, and I think we shall soon see them entering into the bedding arrangements of every garden. The old double white has been very serviceable as a white bedding plant, its flowers being very effective in flower beds or ribbon borders along with Scarlet Pelargoniums, and why should we not use Pyrethrums now that we have them with flowers of better form, when the plants are of better habit, and when they offer a greater variety of colour? Plants with rose-coloured flowers are scarce; in Pyrethrums we have them; and unlike Zonal Pelargoniums they do not run to seed in dry summers, nor are they so miserable-looking after a shower.

Apart from their claims as bedding plants, Pyrethrums are most useful for the summer and autumn decoration of borders, and for growing in pots out of doors. Finer objects than they are in 9-inch pots cannot well be imagined, the flowers equaling those of a Pompon Chrysanthemum in size, and the plants flowering most profusely, and being of stiff, compact habit, with a form that may be called half-pyramidal. They are in perfection from June to October, and plants might be flowered at any time by keeping the flowers pinched off until within a month of the time at which they are required to bloom, not pinching later than the beginning of September for a late bloom under glass. A few of the older kinds sufficient for a beginning are:—

Alfred Salter, reddish rose. Form fine, like a Ranunculus.
Ariadne, rosy lilac. Large.
Boule de Neige, white. Very double.
Comte de Morny, dark reddish rose.
Desdemona, blush. Large.
Dr. Livingstone, flesh white. Large.
Fascination, shaded pink. Fine.
Floribunda plena, rosy pink.
Hendersoni, dark red. Large flowers.
Hermann Stenger, bright rose.
Iveryana, rose.
Madame Furtado, white.
Madlle. Mennier, blush.
Mr. Calot, dark red. Fine.
Noblissima, rose centre. Large and fine.
Princess Metternich, white. Large and fine.
Rev. J. Dix, bright pink.
Roseum plenum, light rose.
Salter, bright rose. Large.
Vilmorin, rosy pink with yellow.

Pyrethrum Golden Feather, with yellow foliage, and so effective as a bedding plant, must not be omitted. It is dwarf, not exceeding 1 foot in height, but it has one great defect, that of producing a number of very starry white flowers, which ought to be pinched off as they appear. It is then very effective, especially in light soils, where if permitted to flower and seed it reproduces itself freely, and very truly. For bedding, it is, perhaps, best raised from seeds sown in July, in light sandy loam, under a frame or hand-glass, until germination takes place, after which gradually harden off the young plants, and prick them out under a wall, or in a sheltered sunny position, in light soil enriched with leaf mould. They will be fit for planting-out in March or April. It is also easily increased from cuttings slipped off close to the stem, the heel pared smooth, and inserted in sandy soil in a shady place, covering with a hand-glass. When they have rooted, plant them out in a

sheltered position for the winter. The cuttings may be made any time in summer, but July or August is the best time, as then they become well rooted, and may be planted-out before winter. When summer propagation has been neglected, the side shoots may be slipped off in March or April, the heel pared smooth, the lowest leaves removed, the cuttings inserted in sandy soil singly in small pots, and placed in a hotbed. Thus good plants may be obtained by May.

Pyrethrums are increased by seed, and by division or slips. By seed new varieties are obtained, and occasionally a few good double flowers, but most of the seedlings are worthless, even for shrubbery borders. Perhaps I may have purchased seed of a poor strain, but I shall in future grow named sorts only, and save my own seed. In sowing, proceed as follows:—Fill a pan to within half an inch of the rim with two-thirds sandy loam, and one-third leaf mould, and then to the rim with fine soil; make the surface smooth, scatter the seeds, and just cover them with fine soil. Place the pan in a frame where there is a gentle heat, and in a few days the plants will appear; keep them near the glass, and harden them off by giving plenty of air. After April it is sufficient to place the seed-pan under a cold frame or hand-glass, or the seeds may be sown out of doors, but I prefer sowing in a pan, and placing it under a frame, so as to have the seedlings up soon.

When the plants are large enough to handle—that is, when they are from 1½ inch to 2 inches high, prick them out in a bed in lines 6 inches apart, and 3 inches plant from plant in the row. The soil should be light, enriched with leaf mould, well dug, and pulverised. A sunny situation ought to be chosen. After planting shade, and keep the plants duly supplied with water until established. They will grow rapidly, and every alternate plant in the lines should be transplanted into another bed when they touch each other, well watering and shading until they become established. They will have plenty of room for the first year. In autumn they may have a mulching, about an inch thick, of leaf soil. When they begin to grow in spring, every alternate plant and row should be taken out and planted in a bed or border, and the plants will then be 1 foot apart. The old bed should be neatly pointed over. If the tops remain fresh nothing need be done, but if they wither cut them off to the live parts. Before autumn they will flower, and pull up every one with a bloom not a half sphere, or as nearly as possible of a Ranunculus form; but if it is of a new colour try to obtain well-formed flowers of the same tint.

If there are varieties which it is desirable to increase, that object may be effected by the division of the shoots which spring from the roots, and which will have some fibres attached to them. These, if put in a shady place, or artificially shaded and kept moist, will soon strike root; but propagation is more rapid if they are placed in a cold frame, or in gentle heat. They strike as freely as Chrysanthemum suckers. This mode of propagation is best practised in spring when the shoots are 3 or 4 inches long, though it may be carried on at all times when there are shoots—say from April to October out of doors, but at other times the protection of a frame is necessary for good rooting, and for speedy establishment a gentle hotbed of 65° or 70°.

Cuttings should be made from the vigorous-growing shoots only, which exhibit no symptoms of flowering, choosing such as spring directly from the stem, and the nearer the roots the better. When 3 or 4 inches long they are of the proper length. Slip them from the stem by pressure downwards. The heel should be pared smooth, and the leaves removed from one-half to two-thirds the length of the cutting, commencing from the heel. They may be placed in a shady position out of doors, in soil consisting of one-half light sandy soil, one-fourth leaf mould, and one-fourth sand, covering the surface to the depth of about half an inch with the latter material. Insert the cuttings up to the leaves, and not too closely together; if they clear each other it is enough. Then giving a gentle watering, cover with a hand-glass or frame, keep close and shaded from bright sun until they begin to grow, after which admit a little air by tilting the light on one side, increasing the amount daily, and when well rooted remove the glass altogether. The cuttings may be potted singly in 3-inch pots, and placed in a cold frame, or in a gentle hotbed, affording a mild bottom heat of 65° or 70° for about a fortnight or three weeks. The time to put in cuttings is from spring to October.

Early-struck cuttings may flower in autumn if shifted as the pots become full of roots, and encouraged with a proper supply of water, adding to the compost one-fourth of old cow dung; or the compost for growing plants in summer after striking may be loam from turf, sandy rather than heavy, one-half, leaf mould one-fourth, old cow dung one-fourth, with the addition of one-eighth of sandstone, in pieces from the size of a pea to that of a hazel nut, and a like proportion of charcoal of the same size, the small of neither being sifted out. The loam should be torn to pieces with the hand, but not sifted, nor must any of the compost, though it should be well mixed. If the points of the shoots be taken out when the plants are 4 inches high, they will branch, and any irregular-growing shoots may be stopped up to August, by which time we shall have fine plants in 6-inch pots. They may be bloomed in these pots, or shifted into 8-inch pots if they are disposed to grow much more and the pots are full of roots.

Thus, by autumn, good plants may be had from cuttings put in early in spring, whilst those inserted in August will be well-established plants either in pots or in a warm and dry situation out of doors. Fine sorts are well worth a cold frame in winter, and the plants being kept in 3-inch pots a large number can be placed in a one or two-light frame. They cannot have too much air, nor be kept too dry, the pots being plunged to the rims in coal ashes, care being taken not to allow the plants to suffer from dryness, nor must they be deluged with heavy rains. In very wet weather the lights should be kept on and tilted at back, but in fine, mild weather drawn off. In frosty weather the lights should be kept over them, and if necessary close, and in very severe frost a covering of mats should be placed over the lights. The plants will be fit for planting out in April for summer and autumn display in the flower garden. Plant in light soil deeply dug, and enriched with leaf mould or any well-reduced manure. For beds or borders the plants should be 18 inches apart every way, or for a close mass or a bed to be quickly covered, 1 foot; whilst for each plant to appear as a specimen, from 2 feet to 2 feet 6 inches will not be too great a distance to plant.

In dry weather the plants should be well supplied with water, especially when they are coming into flower, though they will bear more drought than almost any plant used in the flower garden. If they remain in the ground during winter a mulching of leaf mould should be given about the plants, which may be neatly pointed-in in spring, and the dead parts removed when the plants begin to grow. It is not advisable to remove them early in winter, as they act as a protection. The flower-stems, however, should be removed as the plants go out of bloom. The plants are at their best in the year after propagation; in the second year of flowering they are good, and less disposed to growth; and in the third they are poor; therefore keep up the stock by annual propagation.

If the cuttings are not struck in pots, nor potted after being struck, they should be transplanted by October in a bed, after they are well rooted, placing them 3 or 4 inches apart, and selecting a warm situation and dry sandy soil. In spring they may be removed to where they are to remain for flowering, taking them up with good balls, and watering after planting if the weather be dry.

If the plants are to be grown in pots they ought to be wintered in a cold frame, and in spring should be shifted from the small pots, in which they have been wintered, into 4½-inch pots. This should be done in March, and if no plants have been wintered in pots, the best of those in the open ground may be taken up and potted, if they are cuttings or suckers of last year. It is not necessary to use pots larger than 4½ inches in diameter. The plants may be placed in a cold frame, and kept rather close and shaded until established, then harden them well off, and after April place them in an open situation sheltered from wind, but not shaded. The pots should be set on coal ashes affording each plant enough of space to stand clear of those near it, and leave a little room for growth. Plenty of space should be afforded them in all stages of their growth, except, perhaps, in winter, when room may be a consideration. When the pots become full of roots, and before these are very much matted round the sides, shift into 7-inch pots, and again into 8-inch pots, and for the most vigorous plants even into 9-inch pots, the final shift being given by the time the flower-buds show; or if stopping be practised, the final shift will be required at the end of June, if not stopped earlier in that month; whilst for late blooming the last shift need not be given until July. No potting should be attempted until the roots are matted round the sides of the pots, still it must be done before they become very much so. Good drainage should be given, and especially at the last repotting.

The plants should be well supplied with water, not giving any, however, until the soil becomes dry, and then enough to

show itself at the drainage; on the other hand, the foliage must not be allowed to flag from want of water. After the plants begin to button, weak liquid manure may be given at every alternate watering, up to the time of the blooms expanding.

As regards training, the shoots when long enough should be tied or pegged down, bringing them towards the rim of the pot regularly, so as to feather all round. If they grow evenly no stopping will be needed, but if any shoot is much stronger and longer than the others, stop it; this, by checking growth, will invigorate the weaker. A bush may be formed by pinching all the shoots in a similar manner, the strongest always first, and the weakest last or not at all; and a pyramidal form may be given by pinching the side shoots and encouraging the centre growths. Stopping may be practised almost to any extent, but not after the middle of June, except for very late blooming. Always confine the stopping to the vigorous growing parts, as the flowering parts must not to be stopped; but if they appear before bloom is required, pinch off or cut it away, for until the plant is as large as required, no flowering must be allowed. By stopping some plants and not stopping others, selecting for the latter the plants of the best habit, a succession of flowers will be secured. The plants in pots will be found decorative for the greenhouse, conservatory, or mansion. I do not consider the single varieties worth growing. I like the flowers to resemble half a globe, and to be high in the centre. —G. Abbey.

BEECH AND OTHER TREES INJURED BY COLD.

As many of the Beech trees in the park here appear to be injured on their east side, I have been led to think it has resulted from the cold weather in May and June; but not having heard whether others are similarly served elsewhere, I hardly knew whether to attribute it to that cause or some local one. Elms adjoining them, and equally exposed, have not suffered so much, and in general the Beech may be regarded as one of the hardiest trees. However, as already remarked, the eastern side of most of the Beeches, including many that are protected by other trees, have this season a half-scorched appearance similar to what I have witnessed when a violent cold east wind has injured trees of all kinds in May. That May and June have been very cold months cannot be questioned, and the effects are visible in the small growth, and, in many cases, death of plants not proof against the influence of weather such as is common in March and April; but I hardly expected the Beech would suffer, and yet it is so.

I need scarcely add, that trees which are more tender have suffered also, as the Walnut and Oriental Plane. The latter has comparatively few full-sized leaves upon it, and the Walnut in exposed places has a melancholy appearance. Even in sheltered positions the crop of fruit, which promised to be most abundant in the beginning of May, has all disappeared, having dropped off.

Perhaps some of your readers will report how they have fared, more especially what effect the cold has had on the hardier kinds of vegetation. With us the growth of grass from the 1st of May up to the middle of June, or later, was very rapid, and some other crops prospered also; but, generally, it has been the reverse with everything. As to bedding plants, I feel unwilling to speak further than to say that when we consider the almost total absence of sunshine, the low temperature, cold withering east winds, and other circumstances, the wonder is that they have done so well as they have. Dwarf Kidney Beans and Scarlet Runners are very late, and other crops of a tender kind are also backward. If it should appear that one of the very hardiest of our native trees, the Beech, has suffered by the uncongenial season, the wonder is not that Scarlet Runners and the like have done badly, but that they should have been able to live. I shall be glad to know if the injury to the Beech is general.—J. Robson.

TACSONIA BUCHANANI.

I send a leaf and flower of the new stove climber, Tacsonia Buchanani. I had it as soon as it was introduced, and have kept it potted on and plunged in the bark bed of my stove, so that now it is a plant of considerable size. It was recommended by the introducer as flowering freely on small plants, but this must be incorrect, as I believe it has not yet flowered, even with M. Verschaffelt, who sent it out; at least, it had not done so when I was in his nursery last September, and he would assuredly have noted the fact in his periodical, if it had bloomed since. My first flower opened in the same week that the Editors of the *Gardeners' Chronicle* acknowledged the receipt of a specimen bloom from Mr. Morse, and the flower I send is the first really perfect one I have had since. My plant is growing in an ordinary stove, trained along the rafters, with a Stephanotis. Now that it is strong it is free-blooming enough, but the buds take a long while to open, and the flowers last but a day, which will not add to its merits. The colour I shall leave you to describe [It is a brilliant scarlet], and, in conclusion, I can confidently recommend the plant both for its bold foliage and superbly brilliant blossoms, as a most valuable addition to our stove climbers. It has been stated to be the same as Passiflora vitifolia. I shall be glad to know if others entertain that opinion.—Gulielmus.

AZALEA CULTURE.

(*Read at the United Horticultural Society's Meeting, June 14th.*)

For the compost it is absolutely necessary to have good peat, full of strong fibre. I am careful not to select peat of too great a thickness, my opinion being that a thickness of from 1 to 3 inches is the best. From soils deeper than that I cut off the bottom, and throw it away. The peat is pulled carefully into pieces suitable for the size of the plants to be shifted; the greater the shift, the larger the lumps of peat. The next essential material is sharp sand, and it is almost impossible to obtain sand sharp enough. I also select some soft bricks, and break them up to the size of nuts. As a rule I use about one-third sand and brick rubbish to two-thirds of peat.

The compost being ready, I examine the size of the pot my plants are in, and select pots a size larger—that is, 1½ inch; for strong-growing sorts, a 2 or 2½-inch shift is not too much. The pots must be clean and dry, and there should be from 1 to 2 inches of crocks at the bottom of the pot.

The best time for potting the Azalea is about ten days after the plant has flowered and the pods are picked off—a work absolutely necessary to insure free growth, and without which diminutive flowers are produced. In potting all fine-rooted plants, I find it very necessary to have the ball of the plant thoroughly moist, and on turning it out, if I find it too dry, I soak it in a pail or tub till the water has thoroughly penetrated the mass of soil.

After the pot has been crocked and the plant is ready, I cover the crocks with a little rough peat, place over that a few small crocks and sand, then the ball is dropped 1 inch below the rim of the pot, and a little of the mixture is worked carefully round the ball, rammed firmly, and so on till the soil is filled level with the old ball. The plant is then taken back to the quarters assigned to it—a close damp house—until the growth is made, and the buds begin to harden. Moisture is then gradually withheld.

When the buds attain the size of a pea, the plants are set out of doors for a fortnight or so. Early-forced plants are placed out of doors as soon as the growth is made, and left until the end of September, when all others are housed. Any plants which have not pushed their buds sufficiently I give a little more heat, which will greatly assist them. For flowering in December the plants should be started by the end of September, and a succession may be had in flower up to July.

Another method which I adopt when plants have become potbound, and it is, nevertheless, not desirable to give them larger pots, is to allow them to become dry, turn them out of their pots, and with a sharp chopper cut away 1½ or 2 inches of the ball as the case requires. I prick the ball round to loosen it, dip it in water until it is thoroughly soaked, give it half an hour to drain, and then pot it in the usual way, keeping it shaded for a few days. Plants may be grown in the same-sized pots for years. Great care is required in watering; in fact, every plant grower knows it is of no use writing on watering, as that must be learned by strict attention to the requirements of different plants, but when a plant requires water I give it a good soaking. When growing they require frequent syringing.—G. Baker.

PEWITS AS VERMIN-KILLERS.

Your correspondent "H. E. W." wishes to know the management of the plovers in my garden. The management was last winter simply *nil*. As I stated, owing to the mild winter they did not require feeding, but in a hard winter they want more

food than they can pick up, and must have raw meat minced for them; they speedily become so tame as to eat out of your hand. Mix your meat with worms at first, and they will soon take to it. They also require a shelter of some sort—a door on four supports is as good as anything. The birds were purchased from an advertisement in the columns of this Journal.—I. N. P.

SOME HARDY HERBACEOUS PLANTS.

TRIENTALIS EUROPÆA.—This pretty little plant is a native of Britain and other countries of Europe, also of North America and Asia, always affecting the colder latitudes, or if appearing in the warmer countries, it rises into the mountains. Old Fir or other open moist woods are its favourite haunts. It is a solitary species, and the sole representative in the flora of Britain of the seventh class in the Linnæan system of botany; but it is not a good seventh, the parts of the flowers being often found in fives. The whole plant rarely exceeds 6 inches high, with erect wiry stems bearing a few leaves whorl-fashion at the top, and from the centre of these spring the chaste and graceful star-like white or pale pink flowers with a small yellow eye. On rockwork it must be placed in such a position that shade and moisture will be secured to it, and the soil it most delights in is open gritty leaf mould, or very sandy peat and light loams It does not succeed cultivated in the ordinary exposed mixed border or bed, shade being very essential to its well-being; but it is a most useful plant to introduce into moderately shady moist woods or banks, with a northern aspect, where the natural herbage is not too rank and overpowering. In all cases where the introduction of it is contemplated, the soil above named should be liberally allowed; it well repays a little trouble in the first preparation for its reception. The flowers appear in cultivation usually in May or June, but in nature often a month later. Division is the best method of propagation.

LYSIMACHIA.—This is a useful, showy, and free-flowering group of plants. For a small family there is a considerable diversity of habit in the members comprised in it, but there is little variety of colour, yellow in various shades being the predominating hue.

L. nummularia is one o the prettiest and most interesting. It is a dwarfy prostrate plant, throwing many branches out in all directions from the centre, which in moist situations root at the joints and so spread many feet. The flowers are yellow, and appear in June, and last till September and October if occasionally pinched-in to induce fresh growth. It is useful for a variety of purposes—for clothing rockwork, moist banks, front lines in mixed beds and borders, and for festooning the margins of rustic vases where such ornaments may with propriety of taste be introduced into flower gardens. Native of Britain and Europe generally. A variety with yellow leaves or yellow-variegated leaves, recently introduced, is of considerable value, and will, when more generally known, become a favourite in the flower garden of any style.

L. vulgaris, like the last-named species, is a native of Britain, and Europe generally, appearing also in many parts of Asia and in Australia. It rises erect to the height of 2 or 3 feet, with branching stems terminating in loose leafy panicles of yellow flowers, which appear in July, August, and September. It is not at all a choice-looking plant, but it is valuable for introducing into moist open woods, and for planting on the banks of ponds and streams where the natural vegetation stands in need of improvement, and for lighting up masses of shrubs. It succeeds in any common soil, but delights most in partially shady moist places.

L. punctata, by some considered as a rather well-marked variety of L. vulgaris, is for horticultural purposes not very distinct from that species. It is found in some parts of England and Scotland along with L. vulgaris, and in south-eastern Europe. The spotting implied in the specific name is not of much value.

L. thyrsiflora, native of Britain and other parts of Europe, of northern Asia and America. It is similar in aspect to the preceding species, but dwarfer, and with simple or unbranched erect stems. The flowers are yellow in rather dense racemes, and appear in June, July, and August. Useful for the same purposes as the preceding.

L. angustifolia, from North America, is a very graceful species, growing to the height of 1 foot or 18 inches, with terminal leafy panicles of nodding pale yellow flowers. It is useful for the same purposes as the two preceding species, and is well worth a place in the mixed border. Like the others it delights in moisture, and is not fastidious as to the quality of the soil. The flowers appear in June and July.

L. ephemerum, from several parts of the south of Europe, is very distinct from either of the foregoing species. It grows about 2 feet high, with rather graceful habit, and the stems terminate in handsome racemes of white flowers. The corolla is rotate, with deeply-divided spreading lobes, obovate in form. It flowers in July and August, and is most suitable for cultivating in the mixed border or the margins of shrubberies in good moist soil.—(*The Gardener.*)

BIRMINGHAM ROSE SHOW.

THE eighth annual Exhibition of Roses, horticultural implements, garden ornaments, &c., was held on the 9th and 10th inst., in the Town Hall. This annual Exhibition has now become one of the permanent institutions of Birmingham, and its increasing importance and usefulness are fully evidenced by the fact that nearly all the principal Rose-growers of England—some of them coming from such remote districts as Essex, Hertfordshire, Devonshire, and Somersetshire—have deemed it worth their while to compete for the honours which are awarded to the most successful growers of this garden favourite. The committee of management, and all who take an interest in this delightful exhibition, are to be congratulated upon the unprecedented success which has attended the efforts made to promote the Show this year, and in every respect it is much the best that has ever been held. Altogether, there were no fewer than two hundred and thirty separate entries, by fifty-four exhibitors; but reckoning by former experience, a reduction of about 30 per cent. on this number was anticipated. Contrary to the usual custom, however, all the exhibitors, with the exception of four, put in an appearance, and the result was the largest and finest exhibition of Roses that has taken place in the Town Hall.

Considerable attention was paid to the decoration of the hall, so as to enhance the attractions of the Roses, and considering the short time that was available for this purpose, the manner in which this was executed, under the direction of Mr. J. Cole, was worthy of all praise. For much of the pleasing effect which was produced by the decorative ability of this gentleman, visitors to the Show were indebted to Messrs. Felton & Sons, of the Birmingham Nurseries, Edgbaston, who furnished a handsome collection of stove and greenhouse plants. These choice plants were very effectively displayed in the orchestra, and in the great gallery, and Mr. Cole himself sent some very fine plants, which were admirably arranged in lines down the centre of the tables in the body of the hall. Messrs. T. & E. Jepheott, of Balsall Heath, supplied several collections of Ferns, flowers in vases, and bouquets, which were arranged with much taste on a table immediately underneath the platform; and Mr. A. Bickley, of Moseley, sent a fine collection of British Ferns in pots—all of which were judiciously utilised in contributing to the general effect of the Show.

As regards the show of Roses, the collection was extensive, and the whole of an unexceptionably meritorious character. In the section for seventy-two varieties, single trusses, Messrs. Paul & Son, of Cheshunt took the lead. In this collection the specimens of the Duke of Edinburgh and Miss Ingram, both new flowers, and Alfred Colomb, were remarkable for their great beauty. For depth of colour and brightness of petal, the collection was much admired. Mr. John Cranston, of Hereford, who took the second prize, had also an excellent collection. The same gentlemen were equally successful in the forty-eight varieties, three trusses, taking first and second prizes respectively with collections, all the blooms in which were very fine. In the stand of Mr. Cranston the three trusses of Madame Charles Wood were very large, but rather rough. In the class for twenty-four varieties, three trusses, Messrs. Paul & Son again took the lead with a stand of which it is not too much to say that it was one of the best in the entire exhibition, and that it did not contain a Rose which would not have been a credit to any exhibition. Mr. B. R. Cant, of St. John's Nursery, Colchester, had also a very fine collection, which was awarded the second prize. The same gentleman exhibited, but not for competition, a stand containing about thirty blooms of Maréchal Niel, all in most perfect condition as regards form and colour. This stand, indeed, was quite a feature in the exhibition, and, viewed from the galleries, the rich, deep, golden colour of these beautiful Tea Roses was very striking.

The amateurs also made a splendid show in their various classes. Amongst the exhibitors of peculiar and highly meritorious specimens were the Rev. P. M. Smythe, of Solihull, whose Charles Lefebvre was a remarkably handsome flower; and Mr. W. Brown, gardener to Mrs. Alston, Elmdon Hall, whose François Lacharme, Madame Willermoz, and François Louvat were very beautiful specimens.

In the open class there were many specimens which for intensity of colour and smoothness of petal could scarcely be surpassed.

There was also a very fine collection of bouquets for the hand; that by Mr. John Cranston gained the first prize. In the class restricted to ladies, the best design for dinner-table decorations was that by Miss Cole, of Birchfield, who sent three stands, one as a centre piece, and the other as side pieces. The design by Miss M. Bailey, of Longton, which was also very prettily executed, received the second prize. In both of these designs much decorative skill was displayed, and great pains had evidently been taken with them.

Mr. Perry showed a stand of seedling Verbenas, to three of which—Rising Star, the Rev. J. Dix, and Butterfly—a first-class certificate was awarded. Mr. R. H. Vertegans, of the Chad Valley Nurseries, sent several fine collections of Roses not for competition; and Mr. F. Hodges, of the Imperial Nursery, Cheltenham, exhibited a stand of twenty-four specimens of the white Clove Carnation, The Bride.

A highly commendable endeavour was made to benefit one of the local charities, in connection with the Show, by setting apart a stall for the sale of bouquets, the proceeds of which should be given to the General Hospital.

Amongst the exhibitions of horticultural implements, Messrs. Mapplebeck exhibited a large number of iron ornamental vases, which were distributed in different parts of the hall. In addition, they sent a great variety of croquet and garden seats, garden tables, engines, syringes, &c. Messrs. R. W. Winfield and Co., of the Cambridge Street Works, exhibited a number of beautiful cast-iron garden seats, with imitation cushions, the utility of which many of the visitors practically proved. Mr. W. Spurrier, the electro and silver-plate manufacturer, had a number of specimens of his art, suitable for table ornament.

The general arrangements for the Show were very efficiently carried out under the superintendence of Mr. E. W. Badger, who was most indefatigable in his exertions to insure success. The Judges were, in the nurserymen classes, the Rev. S. R. Hole, Messrs. C. Turner, and S. Evans. For amateurs, Messrs. G. Paul, T. Walter, Gill, J. Keynes, B. R. Cant, and the Rev. R. O. Carter. In the open classes, the Rev. E. N. Pochin, and Messrs. S. Hibberd and C. J. Perry. The following is the prize list:—

Nurserymen.—Seventy-two varieties (single trusses).—1, Messrs. Paul and Son, Cheshunt. 2, Mr. J. Cranston, Hereford. 3, Mr. R. Cant, Colchester. 4, Mr. J. Keynes, Salisbury. Forty-eight varieties (three trusses).—1, Messrs. Paul & Son. 2, Mr. J. Cranston. 3, Mr. J. Keynes. 4, Messrs. H. Curtis & Co., Torquay. Twenty-four varieties (three trusses).—1, Messrs. Paul & Son. 2, Mr. Cant. 3, Mr. J. Keynes. 4, Mr. J. Cranston. *Open to residents in the counties of Warwick, Worcester, or Stafford only.*—Twenty-four varieties (single trusses).—1, Perkins & Sons. 2, Mr. J. Jennings, Shipston-on-Stour. 3, Mr. J. Jackson, Kidderminster. 4, Mr. T. Walter, Leamington. Twelve varieties (three trusses).—1, Perkins & Sons. 2, Mr. J. Jennings. 3, Mr. J. Jackson. 4, Mr. C. Kimberley, Stoke.

Amateurs.—*Open to the United Kingdom.*—Thirty-six varieties (single trusses).—1, Mr. T. Draycott, gardener to Mr. T. T. Paget, Humberstone Hall. 2, Rev. S. R. Hole, Newark. Equal 3, Mr. R. Draycott, gardener to Mr. E. Studd, Hallerton Hall, and Mr. R. B. Postans, Brentwood. Equal 4, Mr. S. Evans, gardener to Mr. C. N. Newdegate, M.P., Arbury, and Mr. T. Laxton, Stamford. Twenty-four varieties (single trusses).—1, Mr. R. Draycott. 2, Mr. J. W. Chard. 3, Mr. T. Lloyd, Warwick. 4, Rev. P. M. Smythe, Solihull. *he*, Rev. G. Arkwright, Penecombe Rectory, Bromyard. Eighteen varieties (three trusses).—1, Mr. C. J. Perry. 2, Mr. R. Draycott. 3, Rev. C. H. Bulmer. 4, Mr. T. Laxton, Stamford. Twelve varieties (single trusses).—1, Mr. R. B. Postans. 2, C. J. Perry, Castle Bromwich. 3, Rev. S. R. Hole. 4, Rev. G. Arkwright. Open to residents in the counties of Worcester, Warwick, or Stafford only.—Twenty-four varieties (single trusses).—1, Mr. C. J. Perry. 2, Rev. P. M. Smythe. 3, Mr. S. Evans, Arbury. 4, Mr. W. Brown, Elmdon. Twelve varieties (single trusses).—1, Mr. C. J. Perry. 2, Mr. S. Evans. 3, Mr. J. Parnell, Rugby. 4, Rev. P. M. Smythe. *Open to residents within four miles of Stephenson Place, Birmingham, only.*—Twelve varieties (single trusses).—1, Mr. C. Cooper, gardener to Miss Anderton, Moseley. 2, Mr. J. E. Mapplebeck, Moseley. 3, Mr. J. Pirie, Erdington. 4, Mr. T. A. Bickley, Smallbrook Street. Six varieties (single trusses). 1, Mr. C. Cooper, Moseley. 2, Mr. J. E. Mapplebeck. 3, Mr. T. A. Bickley. 4, Mr. H. E. Lowe, Edgbaston. *Limited to Amateurs who have never previously won a prize for Roses.*—Twelve varieties (single trusses).—1, Mr. C. Butler, Castle Bromwich. 2, Mr. J. Pirie, Erdington.

Open.—Collection of twenty-four new Roses, sent out by English nurserymen in the spring of 1867, 1868, or 1869 (single trusses).—1, Mr. J. Keynes. 2, Paul & Son. 3, Perkins & Son, Coventry. Best new Rose sent out by English nurserymen in the spring of 1867, 1868, or 1869 (six trusses).—1 and 2, Mr. J. Keynes; 1 for Madame Rothschild, 2 for Mons. Noman. 3, Mr. B. R. Cant, Colchester, for Miss Ingram. First-class certificate awarded to J. & C. Lee for Rose Edouard Morren. Twelve varieties (single trusses), Teas, Noisettes, Chinas.—1, Mr. B. R. Cant. 2, Mr. J. Keynes. 3, Paul & Son. Twelve varieties (single trusses), Summer Roses, including Provence Roses, Moss Roses, Gallica, Hybrid Bourbon, Alba, and Damask Roses.—1, Mr. W. Brown, Elmdon. 2, Mr. Laxton, Stamford. Best Design of Roses and Rose Foliage, arranged suitably for room decoration.—1, Mr. J. W. Chard. 2, Rev. G. Arkwright. 3, Miss Bulmer, Hereford. Best Bouquet for the hand, entirely of Roses and Rose buds, foliage not restricted to that of Roses.—1, Mr. J. Cranston, Hereford. 2, Mr. J. Jackson, Kiddermiuster. 3, Miss Mort, Stafford.

Open to Ladies only.—Best Design for Dinner-table Decoration, Roses to be the only flowers used, foliage not restricted to that of Roses, but left to the taste of the designer.—1, Miss Cole, Birchfield. 2, Mrs. M. Bailey, Stafford. 3, Miss Mort.—(*Aris's Birmingham Gazette.*)

VINES IN AN ORCHARD HOUSE.

I have an orchard house 60 feet by 16, planted with Black Hamburgh Vines in the borders inside, and trained on rods 16 inches from the glass. Two seasons ago the crop was plentiful and ripened splendidly in September; last year the mildew attacked all the Vines, and this year is showing again. Can you give me any advice? My gardener and I differ on the treatment as to air. He keeps the house shut up night and day. There are ventilators to about every 10 feet of roof, and perforated zinc 3 inches deep the whole length of the house along the top of the back wall (the house is a lean-to), all of which he will stop up if allowed. The lights in front are all made to open as well, and there are doors at each end. How much air ought I to give during the day? Ought the ventilators and the front lights to be open at the same time? I notice the berries are larger and more healthy-looking quite at the top, nearest the zinc ventilators. The heat of the house during the day is intense—more like a stove heat. Ought this to be so, the house being merely an orchard house on Mr. Rivers's plan, with no fire heat?—Kate.

[It is not always an easy matter to hold the balance between the employer and employed, and we have often been found fault with for leaning to the weaker side; but whether we be blamed or not, we shall make a few remarks on the above letter.

In the first place, if the description of the treatment is correct, we have no hesitation in saying that keeping the house so closely shut up night and day was one of the surest means to have plenty of mildew; and if the soil was at all damp, nothing could more tend to make the mildew spread. What we are surprised at is, that with such heat and no ventilation, there were not scorching and scalding as well. We presume that the safety-valve in this direction consisted in the 3 inches of perforated zinc at the top of the back wall, left open, we presume, in the warmest days. But for this, ventilators every 10 feet at the apex of the roof would not have been sufficient, and we do not know if there is sufficient ventilation, as we do not know the size of the ventilators. The great use of the perforated zinc, if left open, would be that the temperature of the house would rise gradually, that the hottest and moistest air would escape, and thus, though the house became very hot—"more like a stove heat"—the scorching would be prevented, though the close atmosphere would encourage mildew. What we would consider necessary now would be to leave the perforated zinc open in this hot weather night and day; to sprinkle all the mildewed parts with flowers of sulphur from a dredger or large pepper-box; and to gradually increase the quantity of air, having as much ventilation as possible in hot sunny days from one to two o'clock, and then gradually diminishing the amount until about 4 p.m. The chief object, even in hot weather, of shutting all up, except the strip of zinc at night, would be to enclose a certain amount of sun heat, so as to bring the Grapes on, and thus give them the full benefit of being protected by glass. Diminishing the ventilation in such an unheated house would be effected on much the same principle as lighting a fire for a regular vinery, it being a matter well understood that, even for keeping, Grapes ripened in September will hang better than those ripened in October. We know that in such summers as the last, provided there was plenty of ventilation during hot sunny days, the Grapes would have ripened well with a reduced quantity of air all night, such as would be supplied through the perforated zinc. The management in this case becomes a very easy matter, but we cannot always expect such summers; and for a house of Vines with no artificial heat, we should like the Vines to be growing and ripening at that season when most heat was to be obtained from the sun. For this purpose, in a cool house for Vines, we would give plenty of air in spring, so that the Vines should break slowly and late, and when fairly broken we should gradually lessen air, so that the Vines should have a fair heat when in bloom and setting. After that, if our object was safety and early ripening, we would either leave a little air on all night, or make sure to give a little early in the morning; and as the sun increased in power we would increase the ventilation in a lean-to house, giving the top ventilation first and the front last. On the same principle we would reduce the amount of air again gradually, so as to enclose sun heat.

If this could not be attended to, then we would prefer having a moderate amount of ventilation night and day, instead of keeping the house so close. On large sheets of glass the sun has great power, but with the temperature rising gradually with ventilation, sun heat seldom or never injures. Thus, in a cool glass house, with or without air at night, the temperature at night may range from 45° to 55° or more, and by day rise gradually with ventilation to as much as 85° or 90°, or even more, and no distress will be experienced by the plants; while the same heat in a close atmosphere might be ruinous. Hence, when little trouble and labour are to be given, say in the case of a gentleman who does the work himself, and is away from ten to four, we should from the middle of June, or earlier if the weather were fine, give a little air all night, and before we left in the morning give as much air as would keep the house safe, though the weather should be changeable. This art is easily learned in a few days, and people gain confidence when

they become convinced of the simple fact, that provided air is given early enough, and enough of it to prevent a sudden outburst of sun raising the temperature of the house immoderately, Vines, &c., will not be injured if the temperature fluctuate considerably—say, goes up and down from 60° to 90°, or even 95°, as the rising and falling will be gradual, and there will be no confined moist air within the house, which often does so much mischief when the house is shut up.

To suit a number of inquirers besides "KATE," we have thus alluded to what we deem the correct management of a cool house for Vines in two circumstances—when ventilation can be attended to during the day, and when the most of that work must be done—say, at 9 A.M. and 4 P.M.

So much, then, for the main issues, as to keeping such a Vine house shut up night and day, a practice admitting of no defence except on the supposition that the statement is slightly incorrect, and the probable fact that the gardener thoroughly believed he was doing the best under the circumstances, not in giving no air, but in taking the full advantage of the sun heat. Until the last eight days or so, the season, as a whole, has been dull and cold. We had plenty of nights in May and June in which in such a house the perforated zinc would have been better shut than open. We have a house with Vines and Peach trees together, but in such weather the house was often shut up by three o'clock, and though a little air was given at the apex early in the morning, there were days when that house had little more air than would have been supplied by the 3 inches of perforated zinc. Of course, if there was even a short period of bright sun the air was increased, but in cold bleak days not in proportion to the burst of sun heat, as we knew that could do no harm, with air on to prevent a confined atmosphere and a circulation of light vapour. In the last days of the week air was freely given at back and front, and the doors were opened, but the front air was cut off by three o'clock, and all except a little taken from the back by four o'clock, so that the sun should leave a kindly heat in the house. Most likely the gardener has erred from excess of zeal, to make the most of the sun heat for the benefit of his Vines, and through them for the advantage of his employer. If they unite together and strike out a happy medium as respects ventilation, all will be well, and the cheapest of all heat, sun heat, will be made the most of.

We shall conclude with this advice: In a house of the description referred to, moderate ventilation night and day will be safer in every way than little or no ventilation at any time. The amount of ventilation required greatly depends on the plane of glass. Orchard houses with large squares require almost double the amount of air that would do for a house built in the old-fashioned way, with heavy rafters, and the sash bars not more than 6 or 7 inches apart.]

GROWING ROSES NEAR THE CITY.

HYBRID Perpetual Roses will not flower with me from being near the City. Would I have a better chance with them grown in pots?—F. G.

[The following is Mr. Fish's answer:—

You are quite right, it is the smoke and soot which spoil your Perpetual Roses, clog up the pores of the bark and leaves, and prevent free respiration and perspiration. I cannot perceive what benefit will result from growing the Roses in pots—that is, if you keep the pots out of doors, plunged or otherwise; but you will succeed well with such Roses in pots, if you can place them under glass, syringe well, give plenty of air, and yet keep the smoke and soot out. I have tried several modes, as wool netting, fine gauze, wire, &c., over the ventilators; but, perhaps, there is nothing better than rather fine gauze, or rough muslin, which allows the air to pass through with tolerable freedom, and yet keeps out the smoke and soot, only the gauze must be washed and ironed out as it becomes dirty and clogged up, or soon no air would enter. There is also this great advantage in having your plants under glass, that you can give air freely at night in summer, shut up your house as the morning fires are lighted, and then when most air will be wanted, as at midday, the atmosphere will be clearer and sweeter.

One other mode I practised on a small scale with Roses in London, with the stronger Perpetual, Hybrid China, China, and even a few Moss Roses. The plants were on their own roots, and the method consisted in treating them more like Rose stools than Rose plants. Thus, the shoots made this season were little depended on for a succeeding year. If very strong they were partly pruned in the autumn, and some fern was placed over the stool, covering up a dressing of rotted dung. The partly cutting back concentrated the strength of the plants in the roots, and the lower almost imperceptible buds near the base of the shoots. Frequently the tops looked rusty and woe-begone in winter, and sooty and grimy enough too, but that mattered little, as when April approached we used to cut them all down to the ground, and as the atmosphere became clearer plenty of shoots, strong and with good foliage, came from the stool; and though the Roses were produced later, we used to have plenty of them, and a succession, by carefully thinning out the stronger and the weaker shoots. All the China section, including such kinds as Abbé Mioland, Cramoisie Supérieure, Mrs. Bosanquet, &c., did well, and yielded a profusion of flowers when so treated, but failed miserably when we merely pruned back bushes in the usual way. The Roses were treated on a hint obtained from the fact, that deciduous trees that expand their leaf buds late, do so much better than evergreens in smoky places. Even though the stems and branches of trees are encrusted with soot, the fresh green foliage coming out late in a clearer atmosphere, enables the trees to keep up a rather healthy vitality. Many of the Roses, if left to themselves, are almost half-evergreen, and among the Hybrid Perpetuals the shoots are often covered with small spines or bristles, which keep the soot about them like so many burrs. The China group have smoother bark and stems, and give less lodgment to the enemy; but even in that case, where the atmosphere is greatly smoke-laden, I would advise the cutting-down system. I used to have fine massive bushes of Fuchsias, by treating them in the same way—cutting down to the ground, covering the stools with dung and litter, and better with moss, and removing the covering about the end of April. I cannot, at present, think of any other modes I could recommend for your adoption.]

PHYLLOXERA VASTATRIX.

WE are very sorry to learn that this most formidable of all the enemies of the Grape Vine has made its appearance in England. We were the first to call attention to it in this country as being prevalent on the Continent; little did we then think that it was at our doors. We make the following extract from a letter addressed to us by a gentleman in Kent: "My Vines have all grown well except two, a Mrs. Pince's Muscat and Meredith's Alicante; these did not move more than 2 or 3 inches, and I determined to take them up and examine the roots. Now the roots were swarming with Phylloxera vastatrix; there was also the winged kind. Your description in the May number of the 'Gardener' is very accurate. With a glass of good power you can see it in all its stages, but you can see it with the naked eye. It looks like grains of yellow sulphur in the crevices of the roots; with a high power it resembles small yellow tortoises. It barks all the roots and destroys the Vine." The writer farther expresses a fear that this pest is known to be in some nurseries, but is kept a secret. If so, no time should be lost in discovering which these are, and in getting it "stamped out," to use a phrase only too familiar to us.

The following is the description referred to:—

In some localities of the south of France the Vines are suffering from the ravages of a destructive insect, which has lately been noticed for the first time. M. E. A. Carrière has just published in the "Revue Horticole" an extract from an article which M. J. E. Planchon contributed to the "Comptes Rendus de l'Institut" (1868, page 588). Here is the passage from the "Revue:"—

I will here give a brief *résumé* of all I learnt about the habits of the Phylloxera vastatrix from a series of observations made on the spot, in three short visits to the south of France; also all I noticed with reference to the specimens which I kept in glass bottles during forty consecutive days.

Its best-known form is that in which no trace of wings can be discovered. When the insect is about to lay its eggs (that is, in its adult female state), it forms a small ovoid mass, having its inferior surface flattened, its dorsal surface convex, being surrounded by a kind of fillet, which is very narrow when it touches the thoracic part of its body, which, formed by five rather indistinct rings, is hardly separated from its abdominal part of seven rings.

Six rows of small blunt tubercles form a slight protuberance on the thoracic segments, and are found very faintly marked

on the abdominal segments. The head is always concealed by the anterior protuberance of the buckler; the antennæ are almost always inactive. The abdomen, often short and contracted, becomes elongated towards laying-time, and there can be easily seen one, two, or sometimes three eggs, in a more or less mature state.

The egg sometimes retains its yellow colour for one, two, or three days after it has been laid; more often, however, it changes to a dull-grey hue. From five to eight days generally elapse before it is hatched. The duration of this period depends a good deal on the temperature. The quantity of eggs, and the rapidity with which they are produced, are probably determined by a variety of circumstances—the health of the insect, the quantity of nourishment it is able to obtain, the weather, and perhaps other causes. A female which had produced six eggs at eight o'clock A.M. on the 20th of August, had fifteen on the 21st at four P.M.—that is, she laid nine in thirty-two hours. Other females lay one, two, or three eggs in twenty-four hours. The maximum quantity is thirty in five days. The eggs are generally piled up near the mother without any apparent order, but she sometimes changes her position so as to scatter them all around her. They have a smooth surface, and adhere lightly to each other by means of a slimy matter which attaches to them.

Phylloxera vastatrix (J. E. Planchon).—Female specimens and their eggs. *a*, antennæ; *b*, horns or suckers; *c*, egg plainly visible in the body of the insect; *f*, winged form of the insect. All magnified.

Hatching takes place through an irregular and often lateral rent in the egg, the empty and crumpled membrane being found among the other eggs in different stages of hatching.

During the first period of their active life—two, three, four, or five days, as the case may be—the insects are in an erratic state. They creep about as if they were seeking for a favourable situation. Their movements are more rapid than those of adults. They appear to inspect, as it were, with their antennæ the surface they travel over. The movements of the antennæ are generally alternative, and, if the comparison may be pardoned, are not unlike the two sticks of a blind man, which he uses to explore the ground he is about to tread.

After a few days of this errant life, the young insects seem to fix upon a spot to settle in. Most frequently this is a fissure in the bark of a Vine, where their suckers can be easily plunged into the cellular tissue, full of saccharine matter. If you make a fresh wound on the root by cutting off a little piece of the bark, you may see the "pucerons," range themselves in rows around the wound, and once fixed, they apply to the root their antennæ, which appear like two small divergent horns. At this period of their life, about the thirteenth or fourteenth day after their birth, they are more or less sedentary; but they change their places if a new wound is made on the root, which promises a fresh supply of food.

What sense is this which directs these subterraneous "pucerons" towards the place which is most suitable for them? It cannot be sight, as their eyes are merely coloured spots, and they creep as if they were blind. It cannot be hearing, because they seek no prey but a vegetable tissue. It is probably the sense of smelling; and one may well ask if the nuclei which appear enshrined in the last articulations of the antennæ are not the organs of this function, the seat of which has been so much disputed? Among these non-adult insects, attached by their suckers to the Vine root, are seen, here and there, some of middle size. Their colour is a deeper orange, the abdomen shorter and more squarely formed. These individuals are more sedentary than the others. I have sometimes imagined they might be wingless (apterous) males of the species; but as nothing has happened to confirm this very problematical hypothesis, and as I have seen undoubted females much resembling these examples in colour and form, I incline to the belief that there are no sexual differences among them. A kind of double moult precedes the adult state. The first takes place shortly after birth, the second after laying time. Some uncertainty, however, hangs over the number of these changes, as the cast-off skins are often found mixed up with groups of "pucerons" of different ages, and it is difficult to distinguish them. On the morbid tuberosities of the fibrous Vine roots, or on the offshoots of the roots, the "pucerons" (perhaps better nourished) seem to pass more quickly through the different phases I have described; but excepting that their colour is paler, they present no marked difference.

The winged form of the Phylloxera might easily be taken for a separate species. The rare specimens which I have seen have all come from the "pucerons" nourished on the newly-attacked Vine radicles. In their infant, or it might be called their larva state, they resemble those which I have suggested may be males, but the buckler soon becomes more strongly marked than in these last; and a kind of band seems distinctly to define the separation between this and the abdomen. The sheaths of the wings, triangular-shaped and of a greyish colour, appear on both sides of the buckler. It is easy to predict the advent of a winged insect from this chrysalis. When one of these nymphæ is seen to quit its place and to crawl over the root, or up the side of the bottle where it may have been put, its transformation is near. Soon, instead of a sort of pupa, a beautiful little fly appears, whose two pairs of wings, crossed horizontally, are much larger than its body.

It impossible to doubt the identity of this insect with the "puceron" which formed one of the swarm on the Vine root. The details of the structure of certain organs—the antennæ, claws, tarsi, and suckers—establish their identity.

The horizontal position of the wings completly distinguishes the Phylloxera from the true Aphis, whose wings are always more or less inclined upwards. The two larger wings obliquely oboval and cuneiform, have a lineal areole on the larger basilary half of their outer edge; and this is enclosed in an interior nervure, which answers, I suppose, to the radial muscle. One single oblique nervure (or corneous division) is detached from this last, and reaches to the inner edge. Two other lines start from the end of the wing, and, becoming narrower as they proceed, advance towards the oblique nervure but end before reaching it. These are not, perhaps, nervures, but rather folds, for I have observed them absent.

The inferior wings, both narrower and much shorter, have a marginal nervure running from the base to the middle, but it loses itself in a gentle protuberance, which the wing shows in this place; a radial nervure runs parallel to the first, and disappears before it reaches the same spot.

The eyes, black and relatively very large, are irregularly globular, with marked conical nipples; their surface is granular, but a pointed depression is observed in the centre of each glandule. A round eye-shaped spot occupies the centre of the forehead.

Among fifteen winged specimens of the Phylloxera which have come under my notice, not one has presented any sexual difference. Almost all of them laid two or three eggs, and their death, which happened soon after, may have been caused by their imprisonment in the bottles. Their eggs resembled those of the wingless Phylloxera, and though they were only two or three in number, they completely filled the abdomen of the mother. They were easily seen by placing the insect under the microscope. I do not know how long the eggs remain before they are hatched, or if they always produce the winged form of the insect. It is probable that these winged individuals serve for the transportation of this insect plague to a distance; not that their wings would serve them for a rapid flight—they are too inactive, they move them very little, and in rising from the ground their horizontal position is preserved. My observations were, however, made under very unfavourable conditions, the insect being in a state of captivity; but I suppose that even in a natural state the wind is the principal agent for the dispersion of the Phylloxera, as it is for many of the insect tribe. In any case, the discovery of this form of the Phylloxera provided with wings, and evidently fitted for an aërial life, is sufficient to explain the hitherto embarrassing fact of the rapid spread of the Vine plagues. As to the spread of the disease from one Vine to another, the wingless "pucerons" may suffice for this, as, grouped in great numbers about the lower part of unhealthy Vine stems, they might easily attack the Vines nearest them, even if they be healthy. It may be asked in what manner these insects manage to travel from one Vine stock to another, and how they contrive to reach the fibrous roots of the newly-attacked stocks? Do they

burrow under the soil, or do they not rather travel along the surface of the earth under cover of the darkness and coolness of night, and then, traversing the fissures in the bark, arrive in this manner at the extremities of the roots? This conjecture is a probable one, and the following experiment supports it:—

In a case a yard long I placed some garden soil from Montpellier, a place entirely free from the Phylloxera. In this earth I carefully laid some pieces of Vine cane infested with wingless "pucerons." I placed a hand-glass over each cane, and slightly raised the glass on one side in order to allow the insect to creep out. At three centimetres' distance from the piece of cane I put some fragments of root from a healthy Vine, on which I had made fresh wounds. In twelve hours the following results were obtained: Three "pucerons" had found their way from one of the Vine canes to the nearest piece of Vine root. Some days after, twenty young "pucerons" occupied the same fragment. A few insects were to be found on the other fragments. One piece of root had attracted none, but the Vine cane nearest to it had very few insects upon it which were capaple of changing their places.

A similar experiment has been made by M. Frédéric Leydier at the farm of Lancieux, near Sigondas, a part of the country already infested by the Phylloxera, and by another person near Sorgues. The results of these experiments have not been satisfactory; but this does not prove that, under other conditions, or with greater amount of perseverance, they might not have been successful. It is fortunate that this new enemy to the Vine attacks it in the first instance at the base of the stem, and not underground at the fibres. As it is, a thorough dressing of the bottom of the stem with coal tar will probably prove an insurmountable obstacle to the progress of this destructive insect; but were the case otherwise, it would be very difficult to get down deep enough to reach an enemy so well protected by the depth of the soil.—(*The Gardener.*)

CUCUMBER CULTURE.—No. 6.

There is so much difficulty in procuring fermenting materials for beds, and so much labour and litter are occasioned by them, that they must give place to pits and houses heated by hot-water pipes, that being a less uncertain method of heating, while any amount of heat can be obtained at all seasons with a sufficiency of piping and proper heating apparatus; indeed, there are very few places where Cucumbers are required in winter, or early in the year, in which pits or houses heated by hot water are not provided. Of these, I shall describe one of each.

The pit, *fig* 1, is, perhaps, the best for general purposes, but it has this disadvantage, as compared to a house—namely,

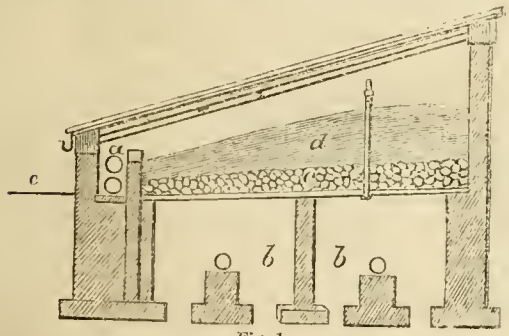

Fig. 1.

that there is no pathway, so that access cannot be gained to the plants in cold weather without drawing up or down the lights. It is constructed in the ordinary way, being partially sunk in the ground. There is a chamber covered with flags, resting on the side walls. Up to that height the back wall is 9 inches thick, and half a brick thick for the remainder of its height. The front wall is taken up much wider, to give a proper width for the support of the flags and the pipes, as well as the 4½ wall dividing the bed from the pipes. The flags are supported in the middle of the pit by a 4½-inch wall. The pipes for top heat, *a*, are in front; those for bottom heat, *b*, in the chamber. The pipes for top heat are flows, and those for bottom heat return pipes. The reason of having a chamber is that one uniform heat may be afforded to the bottom of the bed, and the joints of the flags not being closed, the heat will be communicated to the drainage, *c*, placed on the flagstones, and be genial and regular, which is not the case when the pipes are placed in contact with rubble. The difficulty is to make the heat spread, and it does so completely in a chamber, the great heat immediately over the pipes being distributed, and a uniform heat given throughout. To lessen the bottom heat, if it should become too high, a 2-inch iron pipe is inserted at every 3 feet; it must be long enough to reach from the chamber *b*, through the drainage *c* and soil, *d*, the upper end being fitted with a wooden plug, which can be taken out partly or wholly when it is necessary to reduce the bottom heat. There is no waste of heat by doing so; on the contrary, a moist heat, at times desirable, is obtained in the atmosphere. The heat of the bed should be ascertained by a ground thermometer thrust in about 9 inches. Over the flags 6 inches of rubble should be placed, and on that a thin layer of sods, or the rougher parts of the compost, so as to keep the drainage free; then from 10 inches to a foot deep of soil, leaving from 12 to 15 inches between that and the glass for the plants. The ground level is shown at *e*.

Fig. 2 represents a house suitable for Cucumbers. It is heated by hot-water pipes, and has a chamber, *a*, along which

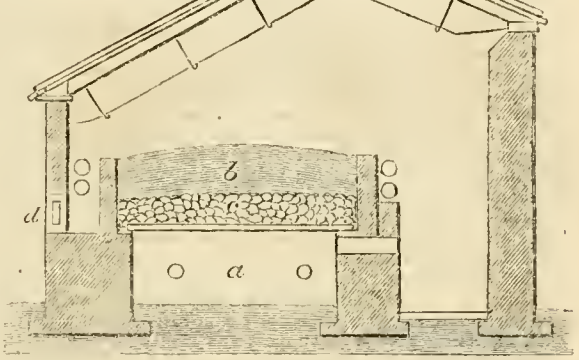

Fig. 2.

run two rows of 4-inch pipes, and they give the requisite heat to the bed above it, *b*. The chamber *a* is covered with slate or flags, thick enough to carry the weight of drainage and soil. In the side of the chamber next the walk there are openings at about every 3 or 4 feet, each of them fitted with a frame and close-shutting door. This may be opened when the bottom heat becomes too high, or shut, as required. Over the chamber there is a depth of 6 inches of drainage, and then the soil, *b* about 1 foot thick. In the front wall openings are left at 4 feet apart, or 3 feet between the openings; these are about 1 foot wide and long, have a frame the thickness of the wall, and are shut by close-fitting doors, as shown at *d*. They are for ventilation, and the air entering beneath the pipes must have its chill taken off before it comes in contact with the plants, and when the top lights are open the thorough ventilation of the house will be secured. The plants are to be trained to a wire trellis fixed not nearer the glass than 9 inches, nor further from it than 12 inches, the former distance being preferable. The wires may run up or across the rafters, and should be not further apart than 6 inches, for when they are wide apart the shoots cannot be tied as could be wished.

The pipes giving top and bottom heat, whether in pits or houses, should be so fixed and contrived that a complete and separate command of both top and bottom heat will be secured, each being entirely cut off by stop-cocks or valves, or worked little or much, according to circumstances.

The sides of the bed, for supporting the soil and drainage, being of 4½-inch brickwork, should be set in cement.

The scale to which the pit and house are drawn is 4 feet to the inch.—G. Abbey.

RHODODENDRON CULTURE.

It is not surprising that a plant possessing so many good qualities as the Rhododendron should become a general favourite. Almost exceeding many of our native plants in hardiness, all

that can be desired in habit, and affording as great a diversity of colour as any flower, it deserves more attention than it usually receives, and certainly more than many plants that are eagerly sought after. Perhaps one reason of its being less extensively cultivated than it ought to be, is the idea that only a certain description of soil suits it. This popular idea is certainly carried farther than is proper, and I will endeavour to show that the plant, or at least the common varieties of it, can be grown in more kinds of soil than usually supposed, so that there are probably many places where it might be planted with advantage, if right means were taken at first to insure success. Unfortunately, this is not always done, and the consequence is a failure, when it might have been avoided, and the cultivation of the plant is abandoned. Perhaps a little consideration of the conditions under which the plant was growing prior to its being tried on such a spot, may tend to explain the reason of failure, and point out a course more likely to be successful.

This plant seems to flourish best in the dry upland peaty soils which are met with in many districts; there its cultivation is desirable, and although for special purposes we often see large quantities of suitable soil removed to a considerable distance to make a bed, this cannot be done in all cases where the Rhododendron is to be grown. On the other hand, it must be admitted that there are many soils and situations where this plant will refuse to grow, but then these are much fewer than is generally supposed, and a due regard to some other points of the plant's culture will show that the number of intermediate sites or soils is very large, and that there are not many neighbourhoods which do not possess a suitable soil. Few plants more readily adapt themselves to removal than the Rhododendron, provided the operation be performed at the right time, and in the right manner. The subject is so important, and the cases where failure occurs so numerous, that some remarks on these, and the mode to obviate them, seem desirable; I shall, therefore, under different heads make the remarks which may seem applicable.

Soil.—Although much as has been written on this, I believe there are few who have planted the Rhododendron extensively on different soils who will not acknowledge they have been several times deceived in the results. Either the plants have not succeeded well when they were expected to do so, or they prospered where they were scarcely expected to grow at all; in fact, the soil requisite to support the healthy growth of this plant is far from being generally understood, and often a just knowledge of the matter is only attained by a trial. A number of plants are tried on some soil that appears to be suitable, and the result watched with interest; if successful, all is well, but if otherwise, the ingenuity of the planter is set to work to ascertain the cause, and a trial elsewhere is, perhaps, determined upon. I will now direct attention to the soils and situations in which this plant is found to thrive with more than ordinary luxuriance, and I will endeavour to point out how far they can be imitated elsewhere.

In taking a casual survey of certain districts, it will often be found, that although a certain class of soil generally prevails, now and then patches of quite another kind are met with, entirely surrounded by soil of the prevailing character, and varying in size from less than an acre to the extent of several parishes, and it not unfrequently happens that suitable sites for the Rhododendron occur in such isolated plots. For instance, some places in the neighbourhood of Dorking are well adapted for the growth of the plant in consequence of the favourable soil cropping out, while the district generally is chalk, with a thin crust of overlying soil almost as white as the chalk itself; yet here and there patches of peat, or a close resemblance to it, meet the eye, while farther westward in the same county peat appears to form the staple soil of the district, extending from almost the centre of Surrey a considerable way into Hampshire, with occasional breaks and irregularities. This neighbourhood, so favourable to the growth of the Rhododendron, has been taken full advantage of, and some of the largest nurseries for the rearing of plants have been formed there.

Other districts also furnish similar sites. A peaty soil well adapted for the purpose exists in large breadths throughout many of the midland and western counties, Cornwall affording as many varieties of soil, with as large a proportion favourable to the growth of this plant, as any county. Speaking, too, without a thorough knowledge of the matter, I believe most of the eastern counties possess a much less extensive range of dry upland peat, although that of a marshy kind may be plentiful enough. Large tracts, however, exist in Derbyshire and Staffordshire, but the wet mosses of Lancashire have to endure a course of draining and cultivation before they become fitting abodes for this highly ornamental plant. Farther north peat is plentiful, and it is questionable whether any spot in the northern part of the kingdom can be found which is ten miles from a peaty moor, or some place of a like kind. Indeed, I am certain that there are not many places in any part of the kingdom half that distance from some spot where the Rhododendron will flourish, for a black peat is not the only soil that it will thrive upon, as it often exhibits every appearance of vigorous health on soils that to an ordinary observer look the very opposite of peat, and these, too, so different from each other, that I am convinced the numerous places suitable for the growth of the plant, have not yet had a fair trial. The black sandy peats of Surrey and elsewhere, with scarcely a stone in them as large as a boy's marble, bear no resemblance to some upland gravels, where stones varying in size from that of a cricket ball to a bean, form at least three-fourths of the staple material the plants have to grow in, and yet fine healthy plants are met with blooming abundantly.

Colour of soil is no criterion, for a light grey, bright yellow, and now and then a dark red, as well as all intermediate colours, seem to answer almost as well as the black peat, while occasionally the latter is rejected. Most low-lying peaty morasses are unsuitable, especially those from which peat is dug for fuel. A period of cultivation may bring them into a suitable condition, but such peat is not so in its crude state; indeed, I hardly know what crops are most suitable for low, flat, peaty mosses, scarcely raised above the ordinary water level. I would caution the inexperienced against using this boggy peat in the formation of Rhododendron beds, as I have seen evil results more than once arise from its being employed. I cannot clearly say why it is so, but it would appear that the long period during which the moss has been soaked with water, has rendered it unfit, for a time at least, to support vegetation of any kind, except the few species which occupy it in its natural condition, and the Rhododendron is not one of them. I have seen several fruitless attempts to obtain a healthy growth of this plant in situations of the kind referred to.

A soil which of itself contains all that is wanted for the well-being of the Rhododendron, is infinitely superior to any mixture of ingredients that the most skilful or scientific operator can make. Although many plants seem to relish the composts made for them, it is but seldom the Rhododendron does so, while very often the worst results follow. Therefore, when the natural soil of the place appears to be favourable to the growth of the Rhododendron, it is best to let it alone. Adding other materials is often injurious instead of beneficial.

When the natural soil presents the features which are favourable to Rhododendrons, try to grow these. The indications are weeds and other natural growths, and after much experience I have found no reason to depart from an opinion I gave many years ago, that one of the best tokens of a soil suitable to Rhododendrons is the common Foxglove, which if seen growing extensively in a wild state, I regard as denoting suitable soil—as much as the Heath, and certainly much more so than the common Brake Fern, although both the latter are generally associated with the Rhododendron when it is left to Nature. Some allowance must, of course, be made for the forms under which each is found; usually the Brake (Pteris aquilina), disappears in tilled ground, but this is not the case with the Foxglove, the latter flourishing in dry ground; while the wild Heath is often found in positions where there is scarcely the depth of soil necessary for Rhododendrons. Amongst trees, the presence of Birch and Scotch Fir often indicates a suitable soil; that of Beech the contrary. Furze is often found along with Heath, but it is not so safe a guide as the Foxglove. Perhaps, however, the Bilberry or Whortleberry may be taken as the criterion of a first-class Rhododendron soil; but this plant is not so widely disseminated as the preceding, and Rhododendrons will thrive well where this highland fruit is rarely met with, often in places far removed from it and similar moorland productions.

As compared with the greater proportion of the land adapted for agricultural purposes, that suited to the Rhododendron would be regarded as poor and unprofitable, producing very indifferent grass crops, and not the best of corn. When the depth is sufficient, Potatoes may be grown, as on the extensive levels of western Lancashire; but in the latter case the benefits of the soil are more than neutralised by the natural disadvantages of the strong sea breeze. Besides, generally the

Rhododendron requires an elevated rather than a low situation, although it does not suffer in the latter, and it can endure any degree of cold which occurs in England.

A gravelly soil sometimes suits Rhododendrons, sometimes a certain kind of sand is equally beneficial, while now and then ground composed almost entirely of stones, and these often large ones, seems equally serviceable in supplying the wants of the plant. At a short distance from where I write, many hundreds of Rhododendrons are growing in a soil of the latter description; stones angular, as if recently broken, being mixed up with a yellowish soil by no means prepossessing in appearance, and the stones forming at least two-thirds of the whole. Many of them are three or four times the size of road metal, and a less likely place for success could not well be found, yet the plants flourish remarkably well in it; and during the hot weather we had last summer, I did not perceive indications of any flagging or injury in any of the plants at that place, while at others full-grown plants in prepared beds succumbed to the heat and drought. The situation is elevated, being 400 feet or more above the sea level, and the stones found upon it are hard and well-adapted to road-making, although widely different from flint and Kentish rag. It cannot be too well known that the character of the stones found upon land constitutes an important feature, and their too extensive removal has often been attended with bad results.—J. Robson.

(To be continued.)

NOTES AND GLEANINGS.

We are requested to state that plants will be received at the Royal Horticultural Society's Manchester Show, up to 9.30 A.M., on Monday, July 19th, and fruit and cut flowers up to 11 A.M. This arrangement, we think, will be most satisfactory to exhibitors, as it will enable a large number to leave their homes on the morning of the Show, instead of on the Saturday, to the great deterioration of the beauty and freshness of cut blooms especially. Without counting numerous entries in the cottagers' classes, there are upwards of 430 entries of Plants and Flowers, and 400 of Fruit and Vegetables.

—— Hamburg International Exhibition.—Her Majesty has graciously intimated her intention of offering a silver cup for the best collection of Grapes, to be competed for under certain conditions at this Exhibition. The arrangements for the transmission of horticultural specimens, both fruit and flowers, we are informed, will be such that it will entail but little expense on exhibitors, who should at once communicate with Mr. Eyles, Royal Horticultural Gardens, South Kensington.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Let an abundant supply of *Brussels Sprouts*, *Kale*, *Savoys*, and *Broccoli* be planted-out as speedily as ground can be obtained for them; and where it cannot be had at present to the usual extent, see that the plants are either pricked-out or sufficiently thinned to allow of their growing dwarf and strong. If a good portion of old Mushroom-bed dung were mixed with the soil before pricking-out, the roots would run into that, so that the plants might be removed with balls, and would hardly suffer from the shift. *Cabbages* sown at this time will afford a late and very useful supply of young heads. Sow *Cauliflower* and Walcheren *Broccoli*. Ridge-out a good portion of *Celery*, and slightly earth-up the early ridges; also plant-out *Leeks* in strong, deep, heavily-manured land. A crop of *Dwarf Kidney Beans* should be sown under a south wall for a late supply. If not already sown, lose no time in putting in *Lettuce*. In some instances *Potatoes* are reported to be diseased; those on soils most unfavourable to their keeping sound should, therefore, be taken up and used first. Prune-off superfluous shoots from *Tomatoes* against walls, that they may not shade the ripening fruit. The leading shoots may be pinched-out when sufficient fruit is set; this will assist in ripening the crop.

FRUIT GARDEN.

Look over espalier Pear, Apple, and Cherry trees at least once a-week, and stop and shorten the shoots. The removal of superfluous wood may also be effected at this time with advantage to both the tree and the fruit; it is always advisable to afford the latter the advantage of full exposure. Let the shoots of Peach, Apricot, and Plum trees be trained at once to the wall. Proceed with the layering of Strawberries for forcing, and let them be kept watered. Fruit trees in general may now be budded.

FLOWER GARDEN.

Go over beds frequently, keeping the young shoots of Verbenas neatly regulated and pegged down until the surface of the ground is well and fairly covered, after which the shoots of most varieties may be allowed to ramble at liberty. Keep down weeds, and if the weather should be such as to render watering necessary, do not let the plants feel the want of moisture at the roots. Cuttings of choice herbaceous plants, Carnations, Picotees, &c., put in early, should be pricked-out or potted immediately they are struck, in order to become established. Early-struck Pansies may be planted-out for early blooming. Young seedling Wallflowers, Brompton Stocks, Sweet Williams, and other biennials, should either be planted-out in reserve beds, or where they are to flower. The propagation of bedding plants must soon be commenced; therefore, make notes of desirable new kinds. The present will prove a favourable time to propagate by cuttings most tender kinds of Roses. Choose the ends of the shoots for the purpose, with the bottom part partly ripened. Noisette, Bourbon, China, and Hybrid Perpetual Roses, will strike freely in sandy soil, if selected as just directed. Cover the blooms of Carnations and Picotees as they expand, placing cardboard collars beneath them. Layering may be commenced, beginning with the grass or shoots which are most forward. A stone placed immediately over that part which is pegged in the ground, will speedily insure its rooting. Look to Dahlias, thin-out where required, stake, tie, mulch, &c. As the pipings of Pinks root, prick them out in good ground. It will be advisable to place some in small pots, to shelter during the winter. We again urge on all cultivators of those beautiful flowers, the Ranunculuses, to watch their ripening, take them up as the leaves turn yellow, and allow the tubers to dry in the shade. Seedlings in pans or boxes should be placed under cover, and in the course of a few weeks, the tubers, which are often very small, should be carefully taken up. Some florists allow them to remain in a dry state until the time arrives to plant them in spring. Cut off the seed vessels of Tulips, and lay them up to dry; trench over the bed intended for autumn planting, and prepare the soil necessary to renovate it.

GREENHOUSE AND CONSERVATORY.

If bright summer weather should set in, the beds and borders of the conservatory must be liberally supplied with water, and specimens or twiners, upon which red spider is likely to be troublesome, should be well washed with the garden engine as often as may be necessary to thoroughly clean them. Plants in bloom must not, however, be dashed overhead with the engine; everything blooming in pots should, therefore, be moved out of the way, and other plants spared as much as possible. If former directions have been attended to, little inconvenience will be experienced from red spider, except, perhaps, in the case of plants in a weakly state, or in ill health, which should be placed by themselves, and receive special treatment till their energies be restored. Remove all decaying leaves and flowers the moment they are perceived, and endeavour to have a good supply of specimens in full beauty, to take the place of such as may be going out of bloom. Greenhouse plants generally should now be out of doors. Most hard-wooded plants in frames will likewise be benefited by exposure to night dews; for that purpose, therefore, the lights should be removed in the evening, replacing them in the morning, and shading during bright sunshine, but giving air freely both back and front, or, which is better, tilting the sashes at the sides—a practice which does not subject the plants so much to currents of drying air. Plants in want of more pot room should be shifted as soon as possible, so as to have them well established before winter; but in shifting now, care must be taken to have both balls and soil in a proper state as regards moisture, and the plants must be carefully shaded, so as to keep the atmosphere as moist as possible for a week or two after shifting. Let any repairs required to be done to plant houses be seen to while their occupants are out of doors. Show houses should now be kept as gay as possible, especially the conservatory, which must be supplied with the finest plants in bloom from the reserve houses. Carefully tie out the different varieties of Lilium lancifolium before they come into flower. Two other good autumn plants should likewise have similar treatment—viz., Crowea saligna and Plumbago capensis; these are invaluable for purposes of autumn decoration as are also the different kinds of Kalosanthes. Shift Chrysanthemums, and stake them securely as they advance. The stock of autumn and winter-flowering plants should not be

stopped after this, but ought to have every encouragement to assist in ripening their wood early, that no difficulty may arise in flowering them at the time wanted. Daphnes, Oranges of different kinds, Myrtles, and Gardenias intended for forcing should be removed to a cool, airy house to rest.

STOVE.

If there are sickly or bad-rooted specimens here, they must be frequently examined for red spider, otherwise they will become a nursery for this pest, from which it will soon spread to adjoining plants. See that young growing stock is not allowed to suffer from want of pot room, and attend carefully to watering, giving manure water to all plants in free growth that enjoy it. Gardenias, &c., which have been removed to the conservatory while in bloom, should be replaced in heat as soon as their beauty is over, in order to allow of their growth becoming ripened before the dull, cloudy days of November set in. Although shading Orchids must now be promptly and carefully attended to, allow them as much light as they will bear without injury, using a very light screen when absolutely necessary. Keep the foliage clear of insects and dust by frequent syringings or spongings, as may be necessary.—W. KEANE.

DOINGS OF THE LAST WEEK.

THE week up to last Friday was dull and cloudy, and yet what a hay week it has been. "Make hay whilst the sun shines," is all very well, but too bright and fierce a sun parches the hay, and extracts much of its nutritive properties. Great breadths of hay were carried in first-rate condition, though it had scarcely a gleam of sun, never was wetted by a shower, and scarcely was damped by dew, as we used our small grass-cutting machines on the lawn at six in the morning, a thing we can rarely do. Such hay has a peculiar beauty and greenness, and was thoroughly made with a turning or two, giving out when stacked an odour like a tea chest. We never knew such a good week for saving fine-made hay, and the comparative absence of sun, and a dry atmosphere, were just the conditions to leave the best properties in the hay. The bright sun has told on everything at last. Cauliflowers and other vegetables, after the dull weather, began to flag, and to make sure we gave water to the most exposed Calceolarias. Surface-stirring the ground was our great resource for retaining moisture and excluding extra heat, as we found that cracking was commencing in our heavy soil. In flower beds, even the spaces next the grass, and the outsides generally, were showing cracks, and the filling them up, and preventing more being made, were effected by surface-stirring with a Dutch hoe. In most departments, the work was chiefly of a routine character.

KITCHEN GARDEN.

In this department we managed to plant-out much, to prick-out more, and to pretty well attend to the wants of all. Our water at hand is getting a little low, but there is a fair supply in ponds at a distance, and whilst we economise what is to be had near we use some from a distance, believing that a good shower will come ere long, renewing our supply, and benefiting the Turnips in the fields. These will not greatly suffer as yet, as in uncropped land there is plenty of moisture beneath. What a difference the cropping makes. Some of our ground that stood uncropped for a little, turned up fair for moisture, whilst other pieces from which heavy crops were removed, seemed to have lost all the moisture to the depth of 18 inches. It was of no use sowing in soil thus deprived of its moisture, without previously watering the rows before sowing or planting.

We are almost ashamed at times to dwell on such simple details, and would not do so but for the frequent encouragement that it is just such minute details that so many readers want. Thus we read, "Thanks to your hints on sowing Cabbage seeds, I now know I erred in repeated surface-waterings." Well, ours are coming through the dry surface-covering beautifully, and we know they have moisture enough beneath them.

In sowing a piece of fresh Turnips and Radishes we drew shallow drills, and run the spout of the watering-pot along the drills before sowing; thus giving a moist bed for swelling the seeds, whilst the surface will be left dry and open to retain the moisture. In planting Coleworts and Cauliflowers, we draw little trenches, so that after puddling the roots we could water afterwards. To make them all safe in such weather they will want two or three waterings before they can hold up their heads to the sun without flinching, which indicates that the roots have taken hold of their new quarters. Then, if the dry weather continue, we shall turn a little of the dry soil, an hour after watering, into the little trench, and that will do something to arrest evaporation. Here, again, the first Peas out of doors, though still producing, are not exactly in a condition to be worth watering; but the second succession, podding heavily, with Beans between them, show a little distress, and the soil has been surface-stirred, and then watered, and if we could have done so we would have mulched afterwards with litter or short grass.

As a proof of rather close cropping, we may mention that our first Peas were in rows 3 feet 9 inches apart. In the centre between them was a row of Dwarf Fan Cluster Beans, and Beck's Gem, and on each side of that a row of Lettuces between the Beans and Peas. Most likely we shall have Cauliflower on the ground—just a row where the Peas stand, and then another where the Beans are, for succession, the one coming in a little before the other. Allow us to recommend the above little Beans to all amateurs who like a well-flavoured tender Bean, and have little room to grow them in. We have just examined a few of these Bean plants, shaded as they are on each side by the Peas, and find that they average a foot in height above the soil, have from twelve to twenty full-sized pods from 3 inches in length, besides smaller ones, and these larger ones containing each from two to three fine sweet beans. Of course, they do not fill a large dish like the Windsors and the Long-pods, but still as furnishing young soft beans in little room and great quantity, they are exceedingly useful.

With regard to Cauliflowers, which never come amiss, our first crop which, with the exception of a few flowery heads already referred to, turned out very fine, is now nearly over, and the next coming in; but the third and fourth small lots—for we cannot afford a quarter at a planting—began to show the effects of the weather even before the sun became so bright, acquiring a slaty bluish tinge on the leaves, which no Cauliflower-grower likes to see. We watered and watered, but still the distressed appearance did not leave the plants; but on resorting to one of our favourite cures—a little mulching with rotten dung and short grass, the plants improved as if by magic, and have stood the fierce sun without flinching. Unfortunately we have, as referred to lately, put most of our heap of short grass and litter out of sight; but if this weather last, we shall cut what otherwise might have been allowed to remain a little longer, for the purpose of mulching, and even dry litter will be brought into requisition. In many respects mulching becomes a substitute for the watering-pot. In planting afresh we have chiefly used the plants previously pricked-out, and, therefore, to some extent lifted with balls, and watering as they were planted with the trowel was generally sufficient to keep them right. To our readers, then, who are scarce of water, or wish to lessen the labour of *watering*, we would say, Surface-stir the ground and mulch if you can with any rubbish you can obtain, and which will keep the sun's rays from striking on the surface of the ground. A little mulching will render frequent waterings unnecessary. If we have a week of such weather we shall try hard to have some mulching, even if it be long litter or rough grass, along the rows of Peas, Beans, Cauliflowers, &c. The only time when mulching is injurious is when it is used for tender plants, for which the ground, if it is moist enough, can scarcely be too warm. For instance, for semi-tropical plants keeping the ground cool would be a mistake, and all mulching is, therefore, most effectual when used after the ground is warm enough for the plant mulched.

For reasons incidentally referred to we have pricked-out lots of Cauliflowers to be transplanted afterwards when tolerably well established, and it is easy to shade them in such temporary quarters by placing wattled hurdles over them, supported on flower-pots at the corners.

Salading has been good and plentiful, but it will be apt to run to seed, particularly when fully exposed in this weather, and we have, therefore, planted-out some fair-sized plants on the north side of a fence, where they will stand longer and be more crisp than if they had more sun. We shall follow in the same place with successions, for though we believe that the best plan for producing fine Lettuces is to sow thinly where they are to perfect their crop, yet shortness of room makes us often resort to transplanting. Nothing is more improved by a little sweet rotten dung than the Lettuce tribe. Endive to stand the winter must have poorer soil, as the richer it is the more succulent will be the leaves, and the less the chance of standing the winter. For early Endive to be used before the end of October, the ground may be as rich as for *Lettuces*. When anyone wishes to surprise his friends with a very large and heavy Lettuce, almost surpassing common belief, three conditions

are essential—plenty of room, plenty of rotten manure, and plenty of weak manure-watering in dry weather. There are many larger, more showy kinds, but for summer use in small gardens, few, if any, can beat Snow's Matchless; it is so compact and hearts so firmly, that when you take hold of the outside, you might fancy you had the bole of a small tree instead of a Lettuce. To our regret we have lost the true kind. It is often confounded with Snow's Compact Green, a very different though good variety, but chiefly valuable as an early spring Lettuce, after successfully coming through the winter.

We may mention as regards Turnips, that we have been much assisted this season by an early white, called the Flat-topped White. We are unable to say whether it may not be out under some other name, but with us, in earliness, it has been a great acquisition, bulbing so soon, and having but a small head of foliage. We have for years passed off, or tried to do so, crisp White Turnip Radishes for small early Turnips, but with such kinds as the above, even that little ruse will be little necessary.

FRUIT GARDEN.

We are behindhand with summer-pinching, &c., owing to a press of other work, but we hope soon to accomplish all. Some trees require it less this season, feeling the effects of the drought last year. We have been obliged not only to mulch, but to water the later Strawberries. *Birds* are rather troublesome, but some evils at times make themselves blessings. Some scores of pheasant-coops near the garden, gave us swarms of sparrows and other birds, which made sad havoc with Peas and fruit, notwithstanding all efforts to frighten or annoy them. Now, we presume, as the pheasants grow larger, the food given is more agreeable to the sparrows, and there for a week or two they congregated in myriads, and have almost let us alone. Smaller birds might help us with Currants, for these are attacked by honeydew, and many of the leaves are marked on the under side with green fly. As soon as we can we shall remove, or rather shorten, the shoots, and then give a good washing with clear lime water before the fruit changes much, and a future drenching with clean water will nearly clear them of the pest. These and Gooseberries, after gathering for bottling, are heavily loaded.

ORNAMENTAL DEPARTMENT.

Here the fine weather is showing its effects on the various kinds of Pelargoniums. The soil is not too warm yet for them, and therefore we shall not water much nor mulch. Like the Wheat, the foliage is becoming of a richer green from the sun, and the flower trusses are now swelling and opening, so that in process of time we may expect them to be as brilliant as the Calceolarias now are. We never saw the bedders of this family finer. Some flower heads of the low Aurea floribunda are like large Cauliflowers in size. These, as previously stated, were watered last week, and were mulched with rotten dung before this bright sun came, and from that, even in hot weather, we expect a continuous bloom, as the ground with a little surface-stirring will be kept cool. Give a cool, moist soil, and the brightest sun will just suit the Calceolaria.

We hoed all beds where there was the least sign of cracking, and we shall be obliged to do a little planting by way of filling up, which would have been saved but for intruders, such as deer, making free with our edgings and Verbenas. We have the blue Cliveden Pansy eaten to the ground several times, where otherwise it would have been effective. Our good-sized plants of Coleus turned out into beds are standing the sun well. They were mulched with rotten dung after the soil was well warmed.—R. F.

COVENT GARDEN MARKET.—July 14.

Two or three sultry days have largely added to our supplies, especially of Currants, Raspberries, and Strawberries; the latter, however, are far from being first-rate, and this will certainly not be a Strawberry season. Peaches, Nectarines, and Pine Apples are plentiful. For rough goods there is an active sale. Good Lemons and Oranges are becoming scarce.

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely to The Editors of the Journal of Horticulture, &c.*, 171, *Fleet Street, London, E.C.*

N.B.—Many questions must remain unanswered until next week.

Chrysobactron Hookeri.—We are informed by Mr. Smith, the able Curator at Kew, that this plant, noticed in our last number, page 20, is still in the gardens, and is healthy and flowering at this moment. It has been in the collection for the last twenty years.

Stand for Cut Flowers (*H. T., Pilley*).—Any dealer in glass, and most of the London retail seedsmen, could procure you one. We cannot recommend dealers.

Gardeners' Royal Benevolent Institution (*T. U., Plymouth*).—Apply to Mr. E. R. Cutler, 14, Tavistock Row, Covent Garden, London, W.C. He will give you every information.

Chinese Primulas (*In-a-Fix*).—You had better apply to some nurseryman in your neighbourhood.

Muscat of Alexandria Grapes Shanking (*Standstill*).—The berries were smashed into a jelly. Shanking is the result of very heavy cropping and a confined atmosphere, but more generally of deficient root action, and, of course, always appears just when there is the greatest strain on the powers of the Vine. Sometimes shanking takes place when there is a thin crop and vigorous growth; but in that case the evil is owing to the wood of the previous year being imperfectly ripened, or to the roots being too deep and too wet, and therefore the juices absorbed too crude. You will be best able to judge as to the cause. Excessive vigour from deep roots often causes the evil.

Compost for Vine Borders (*James Gornett*).—The best compost you could use for growing Vines would be as follows:—First place a layer of turves of good yellow loam, cut from an old pasture, on the top of the drainage, with the turfy side downwards, then about 2 feet deep of the following, well incorporated together. Three parts of the best maiden yellow loam you can find, one part broken bricks, or old lime rubbish and burnt earth, to every yard of which add half a bushel of ground bones, and half a bushel of charcoal. If your loam is not of a very rich and excellent character, you might add a little well-rotted manure. The addition of manure, bones, &c., is, it must not be forgotten, altogether dependant on the quality of the loam used, which of itself is such an indefinite article, varying from sand to clay, that scarcely any two soils require the same admixture. Some soils, of themselves, will produce better Grapes than others with all the ingredients added.

Ground Vinery (*A Cottager*).—Your Vine wants more action at the roots. A Vine planted in October should have been cut back in winter to from 3 to 4 inches, unless it was a very strong plant. You seem, on the contrary, to have left it at considerable length, which sufficiently accounts for its weakened condition. It should have been cut back, and its energies confined to the formation of one good shoot, which next year would bear fruit. Having been planted so late, the roots had not sufficient action to cause all the buds to break. We should recommend you now to check the growth of all the shoots excepting one, the one nearest the root, which encourage to grow to form the permanent rod, then in winter cut it well back; or, perhaps, you will state the result then, and we will again advise you. Do not allow it to bear any fruit.

Grapes Rusted (*P. B.*).—The berries are rusted. The evil is generally attributed to handling them. We believe, however, it arises from the house becoming suddenly overheated or cooled whilst the Grapes are young. The pressure on the cuticle being excessive it thickens, and rust follows. A sudden increase of heat succeeding a sudden fall of temperature, or the contrary, is often followed by this disease.

Grapes Spotted—Araucaria imbricata Losing its Lower Branches (*J. B. Boyd*).—We should think that the blotching and spotting of your Muscat Grapes are owing to spots on the glass, which should be daubed over to prevent burning. Your Araucaria is worth looking after. Remove the grass, top-dress with 3 or 4 inches of rich compost, and give a good watering. Leaf mould or rotten dung may be used. Standard Roses are injured by bedding plants round them, unless well mulched, and supplied with liquid manure.

Vine Leaves (*T. W.*).—We could discover no trace of mildew on the leaf of a Vine sent. It evidently belongs to one of the Vines that have the under side of the leaves a little downy. The other leaves appeared healthy. If you have mildew, sulphur, give more air, and keep it drier. See answer to "Kate." You will have no difficulty in obtaining a suitable man, if you apply to a respectable nurseryman in your own neighbourhood.

Vines Growing Unequally—Leaves Scorched—Thinning Grapes (*J. Mackenzie, M.D.*).—It is impossible to account for young Vines growing unequally, if treated alike, and all propagated in the same manner. We have seen many houses where every Vine was like its neighbour; but at other times, from similar plants at the time of planting, there has been great diversity. The blotching and scorching of leaves in your case, if the description is quite correct, are most likely owing to a spot in the glass, which must be looked for, and daubed with a little paint. It is very prejudicial to Grapes which set thickly, to leave the thinning until the berries are stoned. Some thin-setters may be left until the best berries show themselves. Mr. Foster's address is Beeston, near Nottingham.

Mildew on Roses (*Centurion, and H. W. E.*).—"I do not use Pooley's tobacco powder, nor sulphur for mildew. If I use anything, it is 2 ozs. of blue vitriol dissolved in hot water and added to three gallons of water. I have had mildew on my wall trees. I cut the points of the shoots off, well watered the roots, and kept the trees freely syringed, and they have grown out of it.—W. F. Radclyffe."

Twelve Roses for Half Standards (*Idem*).—"The best twelve Roses for half standards are Gloire de Dijon, Celine Forestier, Triomphe de Rennes, Charles Lefebvre, Marguerite de St. Amand, John Hopper, Madame Victor Verdier, Jules Margottin, Baronne de Maynard, Dr. Andry, Prince Camille de Rohan, and Duc de Cazes. These will give you all colours, and they are all excellent.—W. F. Radclyffe."

Roses not Blooming Well (*R Powle*).—"You must not be disheartened about your Roses. It has been a disastrous spring. We have had twenty weeks of north-east wind, and till lately but little sun. As you have added to your soil every autumn, it is probable the roots are too far removed from the action of the sun and atmosphere. In November take up all your trees, trench the ground, cut back the roots to their general length, and replant your trees. Remember, though Roses like firm soil, they do not like to be mortared-in. People rarely manure Roses too much. Some varieties, however, do not require so much manure as others. Whether the character of the summer is wet, or hot and dry, I keep the hoe plied over the surface; gently over the roots, and as deep as I can go between the plants. Roses have been blooming here magnificently; I never saw a finer sight. Some of my trees have been in bad health, but they are recovering.—W. F. Radclyffe."

Coniferæ Fruited in England (*P.*).—One of our correspondents in Kent has the following species in cone—viz., Abies Morinda and A. Menziesii, Araucaria imbricata, Cupressus Corneyana, C. Lawsoniana, C. Lambertiana, C. funebris, and one or two more Cypresses, of which the species are not ascertained; Cryptomeria japonica, C. Lobbii; Chamæcyparis thurifera and another Chamæcyparis; Picea cephalonica, P. Webbiana, and P. nobilis; Pinus insignis and P. excelsa; Retinospora obtusa, R. squarrosa, R. pisifera, and R. leptoclada; Taxodium sempervirens; Thuja Lobbii, T. occidentalis aureo-variegata, T. Menziesii, and another Thuja from Pekin; Thujopsis borealis, and Wellingtonia gigantea. He says that several of the above have fruited for many years, but that he has not had Picea Pinsapo in cone yet, although he has a tree nearly 40 feet high. The largest and finest-looking cones are Araucaria imbricata, Picea nobilis, and P. Webbiana, the latter a beautiful purplish-black. All the Conifers you name have produced cones in this country.

Red Spider on Melons (*J. B. N.*).—The leaves appear to have been infested with red spider, though we could not discover any. The only mode of destroying it is to coat the inside of the frame or pit with flowers of sulphur, brought to the consistency of paint by the addition of 2 ozs. of soft soap to a gallon of water, previous to which the plants should be syringed with soot water made of one peck of soot to twenty gallons of water, well stirred up. Whilst wet dust the foliage with flowers of sulphur, shutting up the frame early in the afternoon, a gentle sprinkling of water being given previously.

Dahlia Leaves Holed (*Amateur Gardener*).—We could not say what is the cause of the holes in your Dahlia leaves, but they are probably eaten by some caterpillar or weevil, or by earwigs. If the cause is a caterpillar, you will most likely find it on the under sides of the leaves; if the second, examine the plants after dark with a lantern, place a white sheet on the ground close to the plants, and shake them. The insects would then fall on the sheet. If earwigs are the aggressors, traps should be set. These may be had of any seedsman.

Pear and Apple Trees (*James Newman*).—As you are a yearly tenant we should advise, if your garden is sheltered, Pears on the Quince and Apples on the Paradise stock, both trained as pyramids; if it is exposed, dwarf or spreading pyramids would be most suitable. You may obtain trees which would fruit to some extent next year. If you have plenty of ground, and can afford to plant thickly and thin the trees out, taking out every alternate tree at the end of the third or fourth year, they may be planted 4½ feet apart. You will have room for thirty-six trees, say two dozen Apples and one dozen Pears. *Twelve Dessert Apples.*—One Margaret, two Lamb Abbey Pearmain, two Margil, two Scarlet Nonpareil, two Court of Wick, one Ribston Pippin, and two Boston Russet. *Twelve Kitchen Apples.*—Two Keswick Codlin, two Lord Suffield, two Alfriston, four Wormsley Pippin, two Dumelow's Seedling. *Twelve Dessert Pears.*—One Citron des Carmes, two Williams's Bon Chrétien, two Beurré de Capiaumont, two Louise Bonne of Jersey, two Beurré d'Aremberg, two Bergamotte Esperen, and one Beurré Diel. The best time to plant is early in autumn, after the leaves have fallen.

Grass Seeds for Light Sandy Soil (*J. F. K.*).—Mix 3 lbs. of Meadow Foxtail, 3 lbs. of Golden Bristle Grass, with 4 lbs. of Sheep's Fescue Grass, 4 lbs. of Crested Dog's Tail, and about the same weight of both Italian and Perennial Rye Grass, with 4 lbs. each of White and Red Clover, and double that quantity of Saintfoin. You may also add a little Milfoil and Yellow Trefoil, and a small quantity of Sweet Vernal Grass. The above quantities are for an acre. We would recommend you to work the land well, manure it, and sow the seed in the first week in September. Sow, perhaps, half a bushel of Barley with it for shade and shelter at starting. If you do not object to expense, you might increase the quantities of seeds given.

Cottage Garden Plan (*Amateur, Walbottle*).—We do not think you can well improve your proposed mode of arranging your garden, nor its cropping for another season, beyond being careful not to have such crops as Carrots succeeding any of the Cabbage tribe. In respect to the rows of vegetables running north and south, we do not think in your locality, where all the sun there usually is is wanted, that it makes much difference. In the south of England there are many persons who think that lines running east and west are better, as shading the ground from hot sun; but in a small garden where appearance is regarded, it is common to arrange the lines at right angles with the principal walk, and in your case we would certainly prefer those on each side of the main walk running all one way. We think lime will improve your garden soil, and your proposal to plant Currant and Gooseberry plants on each side of the main walk is good. Herbs may grow near each other, but care must be taken to prevent such robust-growing plants as Balm, from overtopping a more humble neighbour, such as Lemon Thyme. As a useful summer screen to conceal the manure corner, we have seen Scarlet Runners used with advantage, or Peas or Broad Beans might do. Rhubarb is not unfrequently used for that purpose. We hardly know what advice to give you about making Asparagus beds; it is not always that it can be made to do well. Sea-kale is better, but some means of covering it up must be thought of, otherwise as a vegetable without some such mode of blanching its shoots, no good will result from it. It would be better to try all the ordinary vegetables first. We suppose you contemplate having an Onion bed. An article on Asparagus will probably appear shortly.

Exhibiting Ferns (*New Zealand*).—The word "distinct" as used in the Manchester schedule is, where not otherwise stated, intended to apply to varieties. For instance, "twelve Ferns distinct," means twelve distinct varieties of Ferns. Twelve varieties of Adiantum, or twelve varieties of Pteris would either be admissible—any number of varieties in fact, provided there is not more than one plant of each variety. The collection, however, which would be the most distinct in character, including the greatest number of species instead of simply more varieties, other points being equal, would be the most valued, on account of its greater variety of form, and the greater difficulty of their cultivation. There should not, as a rule, be more that two or three plants of any one species exhibited in a collection of twelve Ferns.

Vicomtesse Héricart de Thury Strawberry (*T. M. Rideout*).—Any respectable nurseryman could supply you with plants. Our correspondent is not a nurseryman, and we cannot trouble our contributors with private correspondence. (*J. F. S., Accrington; P. Teale*).—See preceding answer. (*Felix*).—It deserves all that has been said of it. The synonymes given are correct. Whether the nurseryman whose catalogue you refer to had the true sort or not we do not know; and if he had it, possibly it might be of inferior merit in his soil. Apply to a respectable nurseryman, and try it. [We have already had a score of letters requesting "Archambaud" to supply plants, and to enter into private correspondence. Too much inconvenience and expense have been already caused to our contributors by their good-naturedly responding to such requests.]

Seedling Zonal Pelargoniums (*A Subscriber and Constant Reader*).—It was impossible to judge of the merits of your seedling Zonal Pelargoniums. The box contained simply a mass of petals of various shades of colour. To ascertain the merits of seedlings it is necessary that the plant should be seen. The foliage of No 1 is good, but the flowers not now in colour, and No. 9 promises well. The seedlings have this great merit, they produce large and fine trusses; but we cannot discover anything new and distinct.

Gunnera scabra and Aralia Sieboldii Culture (*F. G.*).—Gunnera requires a moist peat soil and the protection of the greenhouse in winter. It is very impatient of dryness. As you have failed to raise plants from seeds three years consecutively, we can only come to the conclusion either that the seeds are imperfect, or that they have been allowed to become dry after germination. We would advise soaking the seeds an hour before sowing them; sow them in peat and sandy loam, in a pot well drained, the soil being watered previously and allowed to become dry merely on the surface. Cover slightly with the same soil, press gently, then cover the pot with a square of glass, and a piece of paper to keep out light and too much air, and set the pot in a shady place in a saucer with a little water kept at the bottom, which will so far prevent the soil becoming very dry. When the plants are up prick off, and ultimately pot separately, and attend as above to keeping the plants moist rather than dry. Treat Aralia Sieboldii much in the same way as respects the seed, but so much attention to moisture will not be required after the seedlings are potted-off. Just after sowing, a little bottom heat and sufficient moisture would bring on the seedlings quickly, and then they could be hardened off gradually to the temperature of the greenhouse and a sheltered place out of doors. Much was expected from the finer Aralias for out-door decoration, but the severe winters some years ago destroyed many of them. We looked recently for a noble specimen of Aralia japonica at Wrest Park, where it flourished in a sheltered corner for years; but it had succumbed, and near its old position there is now a fine plant of the Spiræa Lindleyana, also striking from its fine foliage and spikes of bloom, but far inferior to the graceful Aralia. If, by the above careful sowing, you raise seedlings, we would keep them the first winter in the greenhouse, but try some of them in sheltered places and close to a wall the following summer, giving them some heath mould and leaf mould, along with good loam, at first, and a mulching of half-rotten dung afterwards, the mulching having a different effect from incorporating such rich manure among the roots.

Gentiana veena Culture (*Idem*).—With this beautiful edging plant, only not so good as the upright-flowering, beautiful Gentiana acaulis, much depends on sowing the seed at once when ripe. Keep the seed wrapped up during the autumn and winter, and sow it next spring either in a border or box; most likely, if the seedlings come up, you will have to wait twelve months before many of them make their appearance. We have kept the seed of Gentiana acaulis two years in a box before it vegetated. The best plan is to sow as soon as the seed is ripe, and keep in a cold pit the first winter. The plant is rather particular as to soil; it will not thrive in some places. We used it at one time for edgings, and there is no bedding plant to rival it for richness when it blooms profusely. A deep rather heavy loam suits it best. In planting-out, which we would do at once, we would after digging make the soil rather firm, and add to it a little rotten dung, leaf mould, or heath soil, the first being the best if the soil is not very tenacious. The plants, with their pretty blue-purple flowers, are seldom more than 3 or 4 inches in height. Your other question is answered in a previous column.

Insects (*A Lady in Cheshire*).—They are the larvæ of Lady-birds (Coccinellæ), which feed upon the aphides which infest the Calceolarias in great numbers.

Names of Plants.—(*A. S.*).—Anthericum Hookeri, also known as Chry-

sobactron Hookeri. (*Willey*)—1, Deutzia scabra; 2, Echium vulgare. (*Julia*).—Silene noctiflora. (*H. H. C.*).—1, an Iris, but quite rotten when it reached us; 2, Rudbeckia pinnata; 6, Salvia pratensis, var. rosea; 7, Veronica spicata;' 12, Silene noctiflora; 13, Phlomis fruticosa; the rest next week. (*John Hudspith*.—1, Polypodium vulgare; 2. Lastrea Filix-mas; 4, L. dilatata, the typical form; 3, a variety of L. dilatata.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending July 13th.

Date.	Barometer.		Thermometer. Air.		Thermometer. Earth.		Wind.	Rain in inches.	General Remarks.
	Max.	Min.	Max.	Min.	1 ft. dp.	2 ft. dp.			
Wed... 7	30.054	30.018	71	56	63	59	S.W.	.00	Densely overcast; cloudy but fine; clear and fine.
Thurs. 8	30.061	29.970	76	49	63	59	S.	.00	Overcast, fine; cloudy; clear and fine at night.
Fri.... 9	30.222	30.172	75	38	64	59	W.	.00	Very fine; cloudy but fine; cloudy, cold air.
Sat.... 10	30.314	30.222	79	42	64	59	W.	.00	Very fine; clear and fine; fine but cloudy.

POULTRY, BEE, AND PIGEON CHRONICLE.

FEATHER-EATING FOWLS.

The weather has much to answer for. The Englishman has always reserved to himself the right of grumbling at his fellow creatures, their manners and customs, their clothing and diet, and their means of locomotion. The travelling Englishman invariably not only mutters, but makes exclamations both loud and deep, against a portion of the animal life of the countries through which he passes, and against which his grievance is, that it is neither lodged nor fed by paternal governments, and, consequently, he finds frequent descents made under cover of the night on himself in his own room. This year it seems that one of the plagues has descended broadcast on our fowls. From fanciers of all varieties come the queries—What am I to do? My fowls eat the plumage, the one of the other! All kinds of advice are propounded; direful are the remedies resorted to; negative is the result! Birds of price, from this fell appetite, take the appearance of scarecrows. The loss to those amateurs who are negative dealers is serious, as it is now that they want to sell the adults to make way for the chickens. In our own and in the columns of other journals will be found letters from despairing amateurs, who found that day after day their birds were losing plumage to an extent that induced them to write, under initials and assumed names, letters which delicately described the bare state of their favourites. We believe that two out of three attribute the loss of the feathers to internal fever consequent on the breeding season, east winds, unnatural state of confinement, &c.

Does it ever strike one, how much more is in the present day required of a hen than was formerly? Without going so far back as Tusser and Chaucer, we may in many a standard work find the performance of that hen extolled, who, when she had reared her own brood, quietly by moulting prepared herself for the duties of another season. We had almost written session, for the members of parliament now escape from the nightly session at Westminster, and find repose in addressing explanations and apologies to every little town which furnishes a few votes. So the poor hen. She must lay early. She does so, but then just as she would be going into nursery quarters, and is anxious to sit and rear her first brood, she is reviled because "she has only laid us a dozen or so of eggs, and now wants to sit." He who christened the Pencilled Hamburghs "every-day layers" has much to answer for, because it seems that of later introductions so much more is expected that two eggs per bird per diem should be the average.

The unnatural appetite that has during the present season caused so much trouble and annoyance may, we think, principally be attributed to artificial feeding. Where the food is of a highly seasoned nature, it gives to the fowl a craving unknown to the bird previously, and induces it to peck at everything, in the hope of finding the flavour repeated. The immature feather seems a specially dainty morsel, and the thanks of the poultry world will be due to him who can devise a cure for an appetite so unnatural and so mischievous.

MUTILATION OF FOWLS.

I sent my two best pens of Game Bantams to the Ipswich Show, held on the 1st and 2nd inst., and on the latter day received a note from that town requesting me to telegraph the lowest price of either pen. I replied by letter that they were not for sale, and were under engagements for two other shows. They returned on the 4th inst., at noon, and the best cock had both his sickle-feathers pulled out and laid in the bottom of the hamper, evidently done intentionally to destroy my chance of winning in future. It could not have been done accidentally in the hamper, as it was a good one, well lined throughout, and the bird is not likely to moult for a month or two.

Your readers may form their own conclusions, and I doubt not most of them will agree with me that the offender deserves severe punishment. I am instituting inquiries, and if I can prove my case will not spare expense in bringing the individual to justice.—W. F. Entwisle.

OUNDLE POULTRY SHOW.

The first meeting of this Society took place on the 9th inst., and upon the whole the collection, both of poultry and Pigeons, was unusually good. A very excellent tent, provided with Messrs. Turner's well-known pens, gave excellent accommodation to the competing specimens, but it was noticeable that there was not the usual provision of well-practised hands to pen the birds on their arrival, nor was there any published catalogue, consequently we are unable to give any list of prizes.

Grey *Dorkings* and *Spanish* fowls formed very strong classes, and many of the *Cochins* were also excellent. The silver cup for the best pen of poultry exhibited, was taken by a superb Partridge-coloured cock belonging to Mr. Stephens, of Walsall. Some excellent *Crève-Cœurs* were shown, and well-grown Rouen *Ducklings*. The day was delightful, and the attendance of visitors far exceeded the expectations of the Committee.

Edward Hewitt, Esq., of Sparkbrook, near Birmingham, officiated as Judge.

BEES NOT WORKING.

A stock in a Woodbury bar-frame hive gave me last year a super of about 30 lbs. This season the bees appear far from so active as their neighbours; they have as yet only stored 16 lbs. of honey in their stock box; no super has been given them, and I have seen them bring out many bees in all stages of partial development. A few days ago I saw some drones flying in and out. It is a swarm of 1867. The cover of the hive is formed of an adapting-board, and over that another board not fastened down. To the adapting-board would be attached particles of wax, which I thought would keep the two boards a little apart, and thus ventilate the box; but it is possible I may have kept them too cold, and chilled the brood. What would you advise me do?—J. H. L.

[You may possibly have kept the hive too cool, and have thus chilled the brood, or the bees may have extruded it under the influence of impending starvation induced by the recent unfavourable weather. The obvious course is to lift out the frames and ascertain the state of the colony by actual inspection.]

DISLODGING BEES FROM A TREE.

I think your correspondent, "Old Tree Stump," before cutting his tree to pieces, might try (I cannot promise him success, though I wish I could help in the operation), the effect of smoke; but in such a case, ordinary rag or tobacco smoke would probably be of no avail. Bees dislike wormwood above

everything. If, therefore, he stop up the entrance to the upper hive, and then blow wormwood smoke in at the bottom of the tree stump, he will very likely find that the bees will ascend, and, if he is lucky, the queen will be amongst those entering the straw hive. He may, perhaps, expedite matters by boring a hole about a foot above the entrance, when the bees have ascended some distance, and so follow them up, taking care to keep in the rear. At best he will find it a long and troublesome operation, and, perhaps, it may not be successful after all; but, at least, if he then destroy the tree stump, he will have got rid of a good number of bees, for some are sure to ascend, which will be as well for him, as the operation will not make them good-tempered.

If he secure his bees in a hive, he must not move them away now, unless he first send them for a fortnight two miles off, or they will almost all return to look for the tree stump. He might block up the entrance to the stump, and, cutting it down to about a foot, leave the hive there till, say October, otherwise, as I mentioned before, move them two miles off. He must also not forget that it is now too late this season for the bees to gather their winter supply, so he must give it them. —Henry de Romestin.

FAILURES IN BEE-KEEPING—SWARMING versus SUPERING.

To reply to "A Kent Bee-keeper" satisfactorily, one ought to know much more about the locality, its honey harvest, &c., than is possible for any stranger. I should say that his residence must be exceedingly unfavourable for bee-keeping. One fact seems plain—viz., that the harvest is seldom good enough to allow him to share in it, in which case, probably, supering would be dangerous, unless in exceptional seasons; and as regards swarming, it seems as though he should turn all his endeavours to the attainment of early swarms, or none at all. This sounds comfortless advice; but there are places, happily but few, where bees never will furnish much more than amusement. Has "A Kent Bee-keeper" tried different positions for his bees? For there are sometimes subtle influences at work which we hardly perceive, and which decimate bees very quickly. For instance, a draught of air, not suspected till its consequences were seen, has been known to destroy all the hopes centred in a stand of bees.

First swarms, as a rule, have an old queen, all others a young one. The fact of the old queen going with the swarm, of course makes a break in the breeding, but not sufficient to injure a good hive. Later swarms, however, often do great mischief.

Lastly, as regards obtaining a succession of young queens, it can only be done with certainty in a hive with moveable frames, except by stupefying or driving.—Henry de Romestin.

STARLINGS WHITE.

I have caught in my garden, in Warwickshire, two young Starlings quite white. The parents, which are feeding them in the cage where I have put them, are of the usual colour. Is it not an unusual circumstance for these birds to be white? I cannot hear of any like them having been seen before. One of them has, I am sorry to say, met with an accidental death, and I have sent it to be stuffed. The other seems well. I should be glad of some hints about the proper food for it after the old birds forsake it.—Ornithologist.

[It is a very unusual circumstance, we know only of one instance of the kind. For food, give meat (raw beef is best) cut in small pieces, bread soaked in water, small worms, and occasionally hard-boiled egg chopped up, &c.—Eds.]

OUR LETTER BOX.

Books.—The Poultry-keepers' Manual which you can have free by post from our office for 7*s.* 10*d*; and "Bee-keeping for the Many," price 4*d*, or free by post, 5*d*.

Houdans Plucking Each Other (*E.*).—Are your fowls in confinement? If they are, the plumage is being eaten by themselves. You will be fortunate if the practice is in its infancy, and you can check it by removing the offender. We should consign him or her to the stock-pot. The fowls might give it up for a time, but we believe they would take to it again. "*On revient toujours à ses premiers amours.*" We believe, however disposed they may seem to behave well, their conversion would be like that of a New Zealander, "temporary, very temporary." We have one pen of Houdans almost guiltless of feathers. They are epicures; and as one animal wishing another to nibble at some particular spot bites that spot on his friend, so a Houdan hen will take stock of her companion, and finding a promising young feather on the back, she goes at it with a rush, and, having swallowed it, puts herself in position that her friend may do the same for her.

Black Spanish Hen's Crop Distended (*T. M.*).—We do not like your feeding. Shut the hen up; feed on oatmeal mixed stiff—very little at a time. Feed her often. Let her have a small quantity of water three times per day. She must have none by her. Discontinue sharps, bran, and Indian meal; they blow the crop out. If you follow this plan, her crop will assume its usual appearance in a few days.

Indian Game Fowls (*Moro*).—The scaliness of the legs is not infectious, but we believe it incurable. Kill him. It was first introduced into this country by the Cochins. We only know the Gallus giganteus by name. The heaviest pure Jungle Fowl we ever saw weighed 5 lbs. We have seen Malay fowls that weighed from 10 lbs. to 12 lbs. each. They were not so handsome as the Jungle; we do not think any gallinaceous bird can compare with it.

Black East Indian Ducks (*Helen*).—These are sometimes called the Buenos Ayrean, and even the Labrador, and are black, with a green metallic lustre on the feathers; any brown or white feathers disqualify; even the drake rarely attains to a weight of 5 lbs., and the Duck is 1 lb. less. They often pair, and so does the Musk Duck, and this accounts for the complaint of unfertile eggs when two or more Ducks are placed with a single drake. The eggs are often smeared over with a slaty-coloured matter, but the egg-shell is really a dull white; they are thin-shelled, and weigh about 2 ozs.

Preparing Feathers (*Housewife and Housewife*). — "Whenever any poultry is to be plucked let the pinion and other large feathers be separated from those of the body; these latter are to be picked carefully, that no flesh or skin may adhere to the roots of them, and are to be put into the appropriate bag, after which the large ones are to be stripped from the quills and added to them. On the day following that on which the bread oven may have been used let the bag of feathers be placed in it to dry, and kept there, always excepting, of course, when the oven may be wanted. The bag is to be occasionally hung out in the air on a fine windy day, and beaten with a stick. As soon as there appears to be a sufficient quantity of feathers for a pillow purchase some ticking, and, having had the case stitched round on the wrong side with double 'whity brown' thread well waxed, lay it on a table, and having procured some common yellow bees' wax (yellow soap will, however, be preferable), warm the wax, and rub it all over the ticking on the wrong side, in order to prevent the dust and down of the feathers from coming through the fabric. If neither pillows nor bolsters should be required the feathers can be put into a bed that may have become too empty. The Geese and Duck feathers should be reserved for the best beds, and the 'cock and hen,' as they are styled, are only fit for those that are inferior. It sometimes unfortunately happens that feathers while in the bag contract a taint and putrid scent; this proceeds from carelessness in plucking the poultry, whereby small portions of the flesh or skin are torn off, and adhere to the roots of the quills. To remedy this unpleasant circumstance, and entirely restore them to sweetness, let a copper of water be heated, or to save trouble, make use of the soap water in which the clothes of a family wash have been boiled, and while the copper is boiling dip the bag of feathers, tied tightly at the neck, into it; move them about with the clothes' stick to wash them thoroughly for about a minute; then withdraw the bag, squeeze it against the side by means of the stick in order to express the greater part of the water, and hang the bag in the air, turning and shaking it several times in the course of a few days. When the feathers feel dry and light, and are free from scent, they may be returned again to the oven, and kept aired for use."—(*Household Encyclopædia.*)

Selling Honey (*A Subscriber*).—You had better apply to Messrs. Neighbour & Sons, 127, High Holborn, or Messrs. Fortnum & Mason, of Piccadilly.

Piping before the Issue of a Prime Swarm (*West Suffolk Bee-keeper*).—Mr. Taylor seems not to have known that the old queen sometimes falls a victim either to an assault by a juvenile rival, or a regicidal attack from her own subjects, in which case "piping" may well precede the issue of a prime swarm.

Dark Matter in Comb (*J. W. P.*).—The dark matter in the cells of the bit of comb sent by you is newly-gathered pollen, such as is to be found abundantly in every prosperous hive.

Uniting Bees (*A Two-year-old Subscriber*).—Hive the cast in an empty skep in the usual manner, and as soon as they are quiet, stand the hive containing the bees to which you intend uniting them on a cloth spread on the ground, raising one side an inch or two by means of a stone or block of wood; then dash out the cluster of bees on the cloth close to the raised side of the hive, into which they will speedily run, and which should be restored to its place as soon as they have done so. You seem to have done all that is possible to induce your bees to enter the straw super. The middle of a fine day is the most favourable time for an examination. Bees are best united in autumn by being driven into the same empty hive, and afterwards transferred to the furnished habitation, which they are intended permanently to occupy.

Bees Turbid (*An Old Subscriber*).—Although we hardly profess to give practical answers to such questions, we have submitted your case to a friend well versed in what is called home brewing, and he writes us as follows:—"The present spring has been very prolific in thick beer; some entire brewings have refused to become clear, while in many instances a cask or two have remained so, and the others became bright. It is difficult to account for such a state of things, but it would appear that the external air must in some way have had greater access to the contents of the casks that are turbid, than to the others, and kept them in that condition of muddiness in which they left the vat. In general such beer will come round of itself without much loss of quality, provided acetous fermentation has not set in: but if it has, I know of no better way than drawing it off, adding some boiled sugar, returning it to the cask, and in a week or so putting in some finings, when it may be drunk off quickly, but will then not be so good as the beer which turned out well at first. If, however, only vinous fermentation be going on, the beer will come all right; but after a lapse of three months or more acetous fermentation has probably taken place, and I know of no better remedy than the above. The cause of the difference appears to be a sort of mucilage left in at the brewing, and which is difficult to remove."

From observations taken near London during the last forty-two years, the average day temperature of the week is 74.1°; and its night temperature 50.7°. The greatest heat was 92°, on the 25th, 1844; and the lowest cold 32°, on the 23rd, 1863. The greatest fall of rain was 1.48 inch.

ASPECTS OF SPRING GARDENING.—No. 4.

FOR my fourth and last aspect of spring gardening, I desire to take your readers to the picturesque grounds of Nuneham Park, near Abingdon, the seat of the Rev. W. Vernon Harcourt.

There is one very pleasant feature about the flower garden here—namely, that it is broken up into four distinct sections, each of which is for all practical purposes perfect in itself. The visitor comes upon one of these gardens, and is able to grasp its details without experiencing that uncomfortable sensation of weariness large gardens often produce. Then some woodland or pleasant line of shrubbery, and bits of greensward and specimen trees most agreeably vary the monotony of the flower beds, and another garden is reached, till the whole are gone through. Those at the outskirts of the extensive grounds, and lying away from them on the altitude of the upland on the one side, or forming a kind of natural barrier to the beautiful vistas gained along the expanse of the lowland on the other, are grand woodland glimpses standing out in bold relief against the sky, or, on the other hand, in the line of the horizon on the lower ground. There are here no mountains to form what that marvellous word-painter Ruskin terms "the beginning and the end of all natural scenery;" "the natural cathedrals of the earth, with their natural altars overlaid with gold;" but one can yet look here with happy admiration at the lowland flowers and woods and open skies, filling the mind with intense delight, "because the shadow of the hope of the hills is in them." A peace and repose dwells here that belongs to the hills also, and the inferior landscape that leads to them.

Nestling within the line of the friendly shelter of a circle of trees and tall shrubs is the Rosery, a circular garden with a broad border of Roses next the shrubbery, then a broad walk, then a circular belt of small flower beds, and within this the Rose garden. It is the "circular belt of small flower beds" that furnishes the series of the illustrations it is the purpose of this paper to pourtray. Mr. Stewart, the gardener at Nuneham Park, has now become a spring gardener of some repute, and every season some touch of originality diversifies what had been the arrangement of previous years. Some beds filled with Polyanthuses and fine yellow Cowslips were charming; the dark colours of the former were a good contrast to the latter, and how sweetly the landscape seemed to recall

> "The southern-English scene—
> The Violet-scented hedgerows,
> The meadows' emerald sheen."

Other beds of these simple elements had mingling with them plants of the pretty lilac and white Collinsia bicolor. There were also pretty circles and squares of the white and blue Myosotis sylvatica, alternating with the red Silene and the white Arabis albida. In this garden Mr. Stewart had tried Nemophila atomaria oculata as a spring bedding plant; it has pale blue flowers, with a dark centre, but it proved too tender; perhaps the wet winter and cold spring had seriously affected it. One plant in this portion of the spring garden was particularly effective—the charming pale lilac pink Phlox frondosa; this is always well done at Nuneham, and was as effective as ever on this occasion.

From the Rosery a *via media* of climbers trained over wire arches leads to Mason's garden, a delightful spot in which pleasant greensward abounds, and huge banks of Rhododendrons, and specimen Magnolias, and other stately trees vary the aspect, while but few flower beds are present. This delightful garden may be likened to a grand horticultural epic, written in trees, in flowers, in winding walks, shady arbours, and emerald turf. The spot, so retired and secluded, is so full of pleasantness, that one could not but recall the dear love for the common Daisies of the fields of the old British poet Chaucer, who had towards them such a deep regard that he would lie down among them, and talk to them in his quaint simplicity as if they were his own offspring. Here they peeped up from the greensward in multitudes, like reflected stars in the great azure firmament above. In this garden one circular raised bed was particularly striking. This bed was in four divisions, made by lines of stone in the form of a perpendicular coping running from the centre to the circumference: and it was edged with stone in the same way. The centre of the bed was occupied by a stone pedestal, surmounted by a vase, in which was a glorious plant of Dielytra spectabilis, and round the base of the pedestal was a broad ring of Cowslips. Two of the divisions of the bed were filled with the blue Forget-me-not, and two with the showy Limnanthes Douglasii. Another bed of a similar character had two compartments filled with the pink Silene pendula, one other compartment having Oxyura chrysanthemoides, the other blue Forget-me-not. To this bed there was a broad edging of Stachys lanata. Another diamond-shaped bed had a pillar of Roses in the centre, round this was the purple Honesty; in its turn edged with the white Forget-me-not. Another bed, having a pedestal and vase in the centre, had a ring of Alyssum saxatile round the pedestal, then a broad band of the pretty blue Campanula pentagonia, with a broad edging of the variegated Vinca elegantissima. In this garden is one bed that might be best described as forming on the one side the base of a Prince of Wales's Feather, with two narrow serpentine fang-like beds issuing from it on the other side. This was filled with a double line of Young's Blood Wallflower, a fine single dark variety, much used and commended by Mr. Stewart; and edged with Vinca elegantissima closely pegged-down. There were also two raised beds, in the form of huge stone basons, with pedestals in the centre surmounted by a vase filled with the Dielytra; round the pedestal of one was the pink Silene, edged with Collinsia bicolor; round the other the charming Myosotis dissitiflora, with a ring of the double white Saxifraga granulata next it, and edged with the pretty golden-tipped Stonecrop. These had been planted by Mr. Stewart for trial, and it scarcely needs to be stated that all these will be largely used by him in the future.

On the right-hand of this garden, as the visitor proceeds

from the rosery in the direction of the mansion, is the site of the old orangery within a low stone balustrading; now a cosy arbour, with trellises on either side extending some distance either way, and covered with Wistaria sinensis, Magnolia grandiflora, Clematises, Roses, &c. In front of this trellis-work stood a fine row of Humea elegans, and in front of these large specimen scarlet Pelargoniums, &c., a grand bank of colour. The level of the terrace on which is the orangery is some 2½ feet above the level of the greensward. On the terrace is a small but very neat geometrical garden, the outline of which is worked in Box-edging, and forms a chain border. The groundwork of the chain was formed of Viola cornuta, then in the full flush of its beauty; the centre of each link of the chain being planted with Hyacinths, mingled with Collinsia bicolor. The angles formed at the juncture of the links of the chain, were filled up with the blue Venus' Looking-glass. On either side of the chain pattern was a narrow marginal border filled alternately with patches of London Pride, mingled with Calandrina speciosa and Leptosiphon densiflorus.

Close by, and under the weeping shade of a magnificent lofty specimen of Abies pendula, is a raised tablet inscribed to the memory of the Rev. John Mason, the designer of this part of the beautiful grounds at Nuneham, and which intimates that "George Simon, Earl Harcourt, consecrates this cenotaph to the memory of his friend." Round here were to be seen huge specimen Magnolias in full bloom, the pale tints of M. conspicua alternating into the darker hues of M. Soulangeana, while splendid bushes of Persian Lilacs, Berberis aquifolium, and other ornamental plants lent their aid towards the general contribution of beauty to be seen at this delightful spot.—Via.

(To be continued.)

THE LOSS OF THE PEACH CROP OF 1869.

The failure of the Peach crop of the present season is in every way remarkable, and not only remarkable, but it is also quite unprecedented. There have been seasons in particular districts in which the crop has been equally deficient, but then the loss has been occasioned through some particular agency, and the cause could be satisfactorily accounted for. We know by experience what it is to lose a crop of fruit owing to spring frosts, or even the trees themselves from frost in winter. We have also experienced deficient crops through the paucity of bloom, caused through the badly-ripened wood, on account of some neglect on our own part, or the unpropitious character of the preceding season. This season, however, is different in its causes to all former ones. It is also more general than has ever been known within memory. Throughout the whole of the United Kingdom, with very few exceptions, likewise in France, even at Montreuil, where it may be said to be all Peaches, and in Germany, Switzerland, &c.—indeed, from almost all quarters the reports sent to me tell the same sad tale—"Our late Peach crop is almost a total failure." It is a failure on all trees on the open walls, protected and unprotected. It is a failure in orchard houses, in all unheated houses. It is a failure wherever the trees, at the time of blooming and the setting of the fruit, had not the advantage of a little more heat and encouragement than was afforded in the natural state of the atmosphere.

Such, then, is the general report of the state of the Peach (in which are included the Nectarine and Apricot) crop this season. Whence the exceptions? The reports sent to me are again almost unanimous—"We have abundance of fruit in all our early houses, fruit finer, too, than usual." The Peach crop in all early houses—in all houses which have had the assistance of artificial heat during the flowering and the setting period, is everywhere excellent. I hear of no failures with trees in heated houses, excepting through sheer mismanagement. I hear of but just a few successes, of a few fair crops where artificial heat has not been provided. Mr. Saul reports that at Stourton, in Yorkshire, the crop taken altogether is a good one, and this from trees on the open walls, which had been carefully protected at night and during the times they were in flower. Mr. Kingsley, of Thirsk, also reports a good crop, but whether on trees on the open walls, or in the orchard houses, I am not certain. I hear also of a crop in Ayrshire, and, lastly, a most magnificent crop on trees in pots in an unheated orchard house at Scone Palace, Perth.

Naturally all those who have succeeded in procuring a crop, attribute the success to their own superior management, and I will not be uncharitable enough to consider it otherwise. Doubtless, considerable credit is due in some instances, but it is scarcely fair to suppose that this almost universal failure has been the result of mismanagement. I shall be slow to believe, that at Montreuil such has been the case, or that the fine old Peach trees, which are under the management of our best gardeners, have been neglected. Are we to imagine that in the case of orchard-houses, such skilful practioners as Messrs. Rivers, Pearson, Wilson, &c., have lost their crops of fruit, as they all confess to having done, through mismanagement and neglect? Scarcely so. No! the loss has been occasioned through causes beyond the control of the cultivator, at least with the means he had at his hand for prevention.

But let us inquire a little more closely. The only success of note with trees on the open walls is that of Mr. Saul's; and it is attributed by him partly to the protection afforded the trees, and partly to the splendid healthy condition of the trees themselves, and the fine wood formed during the previous summer. This conclusion is arrived at from the fact of the trees on which their crops are produced having suffered severely from the drought of last summer. There are others who advance the same opinion as to the cause—viz., that it is owing to the extraordinary heat of last summer, which in many cases proved very injurious to the trees. This may, indeed, account for some isolated cases, but I am not prepared to admit it as generally applicable. The failure is far too general to admit of this explanation. In the case of trees under my own immediate charge, as well as those in many other gardens, I never recollect seeing the wood in finer condition, or the buds more plump and promising than they were at the end of last year, which in my opinion was one of the best seasons for Peach trees ever known in this country.

Neither am I inclined, like your able correspondent, Mr. Bréhaut (see page 37), to attribute the cause of this season's shortcomings to "excessive cropping." I am well aware of the evil effects of overcropping, and its weakening influences on the future condition of the tree. With pot trees in orchard houses, it, no doubt, frequently happens that the trees are overcropped, and are, therefore, made to perform their functions the following season; but the simple question is this, Were all or any of the trees which are this season destitute of fruits, overcropped last season? I venture to say very few, at least not sufficient to establish the rule. It is not only trees in pots, or trees in orchard-houses, but trees everywhere, whose blooming, &c., took place at a certain period of the year, and which were not assisted by artificial heat. I think Mr. Bréhant is going too far, notwithstanding his great experience, in assuming that "by carefully regulating the crop on each tree, we can, no matter what the season is, secure a good crop." I approve of Mr. Bréhaut's practice, and congratulate him on his success, which is so much greater than my own and that of many others. But I feel "kind o' jealons." I have some hundreds of trees in and out of pots in orchard houses, and on the open walls. Trees, too, which were not overcropped last year, and which never before failed to produce a crop, but are this season barren. It is altogether a mistake to say, that "by regulating the crop on the trees every year according to their powers of bearing, &c., that they thus acquire a steady habit of production, and are independent of atmospheric changes."

The loss of the crop of this season is distinctly due to atmospheric action—to, as stated by Mr. Pearson (page 421), "a total absence of sun and a cold, damp atmosphere whilst the trees were in bloom. The pollen was like paste, and the blooms were unfertilised. A little artificial heat to dry the air would have saved the crop." Such, then, is the opinion of one of the most successful orchard-house cultivators of the time; but what has Mr. Rivers, the inventor of orchard houses, and the greatest Peach cultivator and experimentalist of this country, to say on the subject? Mr. Rivers states that "the blossoms in March required more warmth and dryness than they had under common circumstances;" and to show that the lack of heat had much to do with it, the following examples are given:—"Early in January forty trees in 10-inch pots were selected from the common lot and placed in a gentle forcing house. These all set well, and produced splendid crops of fruit, whilst those of the same age, in the same sized pots, left in the unheated house, dropped all their fruit." Further, some tall standard trees in the centre of one of the houses, at the greatest distance from the ventilators, are pretty well cropped, while all the others in the same house, as well as everywhere else in the nursery, have entirely failed. And, again, Mr. Stevens, of Trentham, writes, "No Peaches in our

cold houses. Abundance of Apricots; but our trees are trained upon cow houses, &c., so the walls are, consequently, very warm."

Thus, then, we have evidence showing that in almost every case when heat was applied, success has been the result; and in almost every case where heat has been wanting, failure has ensued; and that the cause of the failure is due to the uncongenial nature of the spring, not to any overcropping, or the influence of the past season.

The only single instance of success this season in an unheated house, is that of Mr. Halliday, at Scone Palace, Perth. Last season these trees were splendid specimens of culture, heavily laden with fruit. This season they are again abundantly laden, and Mr. Halliday attributes his success to keeping the house as close and warm as possible during the flowering and setting period. Mr. Halliday ventilates his house only at the top, and the climate of Scotland being colder than our own, some such precaution is necessary. Perhaps a little less ventilation on our part, if we could have dissipated the damp, would have saved our crop.

Peaches, &c., bloomed unusually early this season, and the blooms were as fine as usual, and fully more abundant. The trees remained in blossom a long time, much longer than usual, which of itself was a sign of imperfect setting. They, however, set partially, attained the size of small beans, and then dropped. The trees throughout this long blossoming period had their energies severely taxed, yet on trees where the blossoms were thinned to a minimum, the same result occurred. The whole period during the blooming and setting was cold, damp, and in every way wretched, about the worst that could possibly have been experienced. There was, however, no frost sufficient to do any injury. Better there had been. The Peach will stand 8° or 10° of dry frost better when in flower than stagnant moist air. In April the weather from excessive cold, became suddenly unusually warm for the season, and it was then the fruit fell. The excitement was too great after their long season of lethargy. To this the loss is to be attributed; for it is a well-known fact to all gardeners, that a sure way to lose a crop of Peaches is suddenly to raise the temperature of the house from a low to a high degree.

What lessons, now, are we to learn from the experiences of the present season? or what precautions shall we take to avoid a similar loss in the future? Mr. Pearson counsels "humility"—that is, contentment, or an inward conviction that we have done our best under the circumstances; but, further, he advises "those who can afford it to put pipes in their houses, and so make safe for the future." Pipes are, undoubtedly, of great assistance, but they are also of great expense, and not within the reach of many of those for whom the orchard house is intended. It is also doing away with the true principle of orchard houses, and making them an expensive luxury instead of a cheap enjoyment. Seeing that it is the "first time," as Mr. Rivers says, "since their invention that orchard houses have failed," but, on the contrary, have continuously produced good fruit, I cannot fall in with the clamour against them, or on the spur of the experiences of a single season recommend the additional expense of heating. By another season the tables will be turned, and Peaches be everywhere abundant. So before spending your money, wait a little longer.—Archambaud.

STRAWBERRIES—AND FOR A LIGHT SOIL.

My Strawberry party was held July 16th. Eleven dishes of very fine fruit were set before the company. Fifteen Cockscombs weighed 1 lb. The heat was intense; had they been weighed in the morning, twelve would have weighed 1 lb. The largest (Cockscomb) measured 9 inches round. The sorts used were Frogmore Late Pine, Dr. Hogg, Mr. Radclyffe, Eliza, and Cockscomb. I never saw eleven dishes of such fine Strawberries. The company were astonished, as few people have any at all. I keep on two waterers constantly for Roses and Strawberries, that with manure is the reason of my success, and the size of the fruit. Dr. Hogg and Mr. Radclyffe did not set all their blossoms, but Eliza, Cockscomb, and Lucas set every one. The Alpines, of which Galande, is by far the best, set every blossom. Mr. Peglar, who sends a query, has a light dry soil overlying gravel and chalk; such a soil is not suited to the growth of Strawberries; but if the surface be heavily mulched with rich manure, and the watering pot kept going from the time the berries set till they begin to colour, great crops may be grown. Such was my Rushton land. After the fruit-picking is over, thoroughly drench the land. My opinion of Lucas and Prince Imperial, alias Marquis de la Tour Manbourg is, that Lucas is in all respects a first-rate and splendid Strawberry when fully ripe. The Marquis is a handsome plant, with leaves like one of the Laurustinus family, it is a good bearer, handsome, and pleasant. As Mr. Peglar wishes large and profitable Strawberries, I am inclined to recommend for his soil, Sir Joseph Paxton, Cockscomb, Dr. Hogg (to represent the Queen), Lucas, Trollope's Victoria, Alice Maude, and Empress Eugénie. Such a soil, unless a great quantity of water is used, is too dry for Frogmore Pine, Wonderful, and some other good sorts. People who do not water copiously, obtain one or two large berries, and the rest come to nothing. It is not the fault of the Strawberry. My runners were planted July 1st, 1869. Early establishment is of great moment in this country.—W. F. Radclyffe.

EARLY PEACHES.

In horticulture, as in agriculture, every change brought on by experimental culture, if it be an advance by only a short step in the way of improvement, is a source of real enjoyment to the cultivator. To make two blades of grass grow in a space which one under common culture would occupy, is a gift beyond calculation; to make two ears of Wheat grow over the whole Wheat-growing surface of England, without incurring a heavier outlay of capital than now invested, would entitle a man to a monument grander than any one of the pyramids of Egypt.

I have been led into this train of thought by the result—humble enough, of my experiments in raising a new race of early Peaches, so original in their nature as to make me hope that in a few years, by means of them and their offspring, a revolution will be made in the forcing of Peaches, or at least a great reduction in the expense of producing them. I ought to premise, that in describing these new and interesting varieties, I have been tempted to it by reading Mr. Bréhaut's notice of some of them in your last number, and not with any wish to advertise them indirectly, for they are now in the hands of numerous cultivators, who can supply trees of them. I may as well here describe how I forced my Peaches this season—a very simple mode of culture, and well repaying by the great value of the fruit, the small expense, and little trouble the trees have given.

About the end of the first week in last January three dozen or so of trees two years old (one year in pots), were placed in a lean-to house 10 feet wide, and with two 4-inch hot-water pipes in front, heated by an Arnott-stove boiler (a small saddle boiler). They were in pots from 10 to 11 inches in diameter, and were placed in gentle heat just in the state they were in, without any surface or top-dressing. In the course of a few weeks, the temperature varying from 50° to 60° by day, they put forth abundance of blossoms; air was given freely during the day, and they set a great quantity of fruit. This was gradually thinned down, leaving at the last thinning, when they were the size of walnuts, from six to ten on each tree. As soon as the leaves were developed, and the trees in a fit state to receive extra food, the surface mould was scraped off each pot to nearly 1 inch depth, and a surface-dressing of my usual compost, about 1 inch deep given. This compost, often described, is kiln dust from the malt houses here—a mixture of fine ashes and malt combs—and horse droppings from the roads; one-third of the former, and two-thirds of the latter, mixed, and then saturated with strong liquid manure from a cesspool containing the drainings from cloacæ and the stable, too strong to be used as liquid manure, but most useful and safe when absorbed by the materials just mentioned. The trees were kept free from aphides, and in sunny weather were syringed in the morning. Under this management they showed fine health, and the fruit swelled gradually without dropping while stoning. On the 29th of May the Early Beatrice ripened its fruit, of a deep crimson, and the size of the Acton Scot, remarkably juicy and melting, refreshing, with a nice Peach flavour, but not rich. This curious creature was raised from a stone of my seedling White Nectarine. The flowers fertised with pollen from the Red Nutmeg Peach, the earliest of the old sorts of Peaches, but not larger than a small walnut. Simultaneously with Early Beatrice—I am not sure if it was not a day or two earlier—the Early Louise Peach ripened a nice crop of fruit. These were as large as a medium-sized Royal George Peach (as these Peaches have as yet been grown only in pots, not large, it is to be expected that

their size will be increased), its colour a pale straw, with a light crimson cheek, very juicy and melting, with a most agreeable flavour. This Peach was raised from a stone of my Early Albert Peach, which was raised from an early Clingstone Peach, received from Belgium as Montagne Précoce, a sort now unknown on the Continent.

June 3rd.—Some fruit of my Early Rivers Peach ripened. Although the trees are in small pots, yet the fruit was of a fair size, say 7 to 8 inches in circumference, not 8½ inches in "diameter," as in your last number, a clerical error, probably of Mr. Bréhaut. A Peach 25½ inches in circumference would, indeed, be a wonder, reminding us of the old Spanish gentleman mentioned by Le Sage, I think, in Gil Blas; he contended that the Peach world was in a state of decadence, for in his youth the Peaches were as large as small pumpkins.

The Early Rivers Peach is correctly described in page 38 by Mr. Bréhaut. It originated from a stone of the Early Silver Peach, which was raised from the White Nectarine. The three Peaches above described are the earliest sorts known. The two former, from their bright colour, will be popular as market Peaches. The latter is, perhaps, too delicate in colour and in its flesh, which is more than melting—it is dissolving.

An American Peach cultivator, from New Jersey, was so much struck with the description of the Early Beatrice when it was sent out, that he made a voyage to this country for a supply of trees, which he returned with. He has now 20,000 trees of this sort in his orchards, and declares that if it will ripen a fortnight before the Early York, it will be a fortune to the grower. The single fault of the Early Rivers is to have imperfect stones. When this is the case the fruits split at the apex before they are quite ripe. As this probably arises from the flowers not being perfectly fertilised, it will be good practice to fertilise the flowers with the pollen of some free-bearing sort.

June 12th.—Rivers' Early York Peach ripe. This differs from its parent in having smooth glandular leaves, and never mildews. It ripens as nearly as possible at the same time as its parent, but its fruit are rounder, a little larger, and of a richer flavour. An American pomologist, who tasted it on his return from the Continent, declared it was the finest Peach he had ever tasted, either in Europe or America. Its fruit measured from 7 to 8 inches in circumference, the same as the Early Louise, and I may add, that on measuring some fruit of Early Beatrice, now (July 17th) ripe in my cold orchard house, the tree in a large pot, and in fine health, I find them 7½ inches in circumference, and Early Louise, also ripe and in a large pot, 8½ inches.

June 16th.—Early Leopold Peach ripe. A seedling from the Early York. Shape compressed (flattened), with a rather deep suture, skin pale straw colour, flesh melting and very rich. Size that of Early Louise.

June 22nd.—The Stanwick Early York Peach ripe. This was raised from the Early York crossed with the Stanwick. Its flavour very remarkable and most delicious, unlike that of any known Peach. Its colour crimson, and size equal to that of Early Louise.

June 22nd.—The Early Alfred Peach ripe. This was raised from Hunt's Tawney Nectarine. Its flavour is quite original, partaking of that of the Nectarine, and its abundant juice is most refreshing.

July 2nd.—The Early Grosse Mignonne Peach ripe. This has been for some years our best early Peach. It is really good, but its flesh has not the piquancy of the early seedling Peaches I have named; besides which, it is quite a laggard compared to them, for standing in the same house the trees of the same age, and in the same sized pots, it is fully a month later than the Early Beatrice and Early Louise; this is of great consequence in forcing.

July 8th.—The Grosse Mignonne Peach ripe.

July 10th.—Alexandra Noblesse Peach ripe. Fruit fine, 8½ inches in circumference, and its flavour most delicious.

I have noticed most particularly the ripening of the two latter, as they have hitherto been with the Royal George (which ripened with the Noblesse), our most popular forcing Peaches. All the Peaches I have noticed have been forced in the same house and in the same sized (10 to 11-inch) pots. I have been much struck this season with the small amount of trouble with which Peaches in pots may be forced, for when a youth I used to think that ripe Peaches in May and June required a sort of preternatural knowledge, and I then looked at a gardener who produced them with a sort of awe—as a sort of horticultural Jupiter.

I gathered from three dozen of my young trees, during the month of June only, from sixteen to eighteen dozen of early Peaches, and derived much pleasure from giving them to neighbours and friends when they were rare and dear in our great London garden. A Peach costing 5*s.* soon melts away, like money in the pocket of a spendthrift.—Thomas Rivers.

THE ROYAL HORTICULTURAL SOCIETY'S MANCHESTER SHOW.—July 19th to 24th.

The third provincial Show of this Society, in connection with the Royal Agricultural Society's great meeting, commenced at Old Trafford, on Monday last, and will close on Saturday, Notwithstanding the opening day being a Monday, rendering it difficult for distant exhibitors to show their various productions in the best condition, and at the same time conform to the rules, it is one of the largest, if not the largest, of the exhibitions which the Society has yet held. It is difficult to be precise on the point, writing as we do without the statistics of previous exhibitions at hand; but we shall be much surprised if the entries are not more numerous than at Leicester and Bury St. Edmunds. The Show, as a whole, is good, though there is considerable room for improvement in many of the classes; but distance deterred many from bringing large plants, the hot weather and the duration of the Show others from bringing smaller and more delicate specimens. Still, the classes are well filled, as will be seen by the following reports; and graced by the presence of several of the Royal Family, and held in so densely populated a district as Manchester and its environs, we cannot but believe that the results will not be less satisfactory than those which have attended the Society's previous country exhibitions. Though the site in which the Show is held is none of the smoothest, it has the advantage of being situated close to the Agricultural showyard; still, it is the opinion of most people that it would have been desirable to have held the Exhibition elsewhere if satisfactory arrangements could have been made. There are several subjects, such as the Congress, at which numerous papers are to be read, that we must postpone till next week.

Stove and Greenhouse Plants.—There are numerous groups of these, consisting of flowering plants only, of ornamental-foliaged plants only, and of the two mixed. The leading prizes for this class of plants were that of £25 offered by the Royal Horticultural Society, and the second prize of £15, offered by the Manchester Botanical and Horticultural Society for the best and most effective group of ten fine-foliaged and ten flowering plants. Mr. Baines, gardener to H. Micholls, Esq., Summerfield, Bowdon, Cheshire, takes the first position with a fine collection, though scarcely equal to those he has shown at the previous shows held in connection with the Royal Agricultural Society's exhibition. His collection contains an excellent Bougainvillea glabra; fine specimens of Ixora coccinea, Genetyllis tulipifera, Erica obbata, Dipladenia amabilis in beautiful condition, Erica Fairrieana, 4 feet in diameter, and in fine condition, a tolerably good Franciscea confertiflora, Croton angustifolium and variegatum, marvellous Sarracenias, a magnificent Alocasia metallica, Dicksonia antarctica, Cordyline indivisa, Theophrasta imperialis, a very fine Gleichenia speluncæ, and Dasylirion acrotrichum. Mr. W. E. Dixon, nurseryman, of Beverley, comes second, and has a fine Aphelexis macrantha purpurea, an excellent Bougainvillea glabra, Ixora alba, Yucca aloifolia variegata and Stokesii, Cattleya Leopoldi, and some other plants which do not contrast advantageously with those in the preceding collection. Mr. Baines also takes Mr. Bailey's prize for the most effective exhibition of plants.

Turning now to the general prize list, Class 48 is for collections of nine. In this the first prize was awarded to Mrs. E. Cole & Sons, Withington, near Manchester, who have an excellent specimen of Allamanda nobilis with large flowers, Kalosanthes Madame Celesto Winans, a very good Aphelexis macrantha purpurea, Genetyllis Hookeri, good specimens of Erica Parmentieriana rosea, and Erica tricolor Wilsoni. The second prize goes to Mr. J. Bolton, gardener to W. Worswick, Esq., Birstall Hall, Leicester, for Vinca alba, Clerodendron fallax, a Plumbago, Pentas carnea, Rhynchospermum jasminoides, Medinilla magnifica, Vinca oculata, Bougainvillea glabra, and Stephanotis floribunda. The third prize was awarded to Mr. W. E. Dixon, of Beverley. In his collection we noticed Roella ciliata and a pretty Erica Bothwelliana. In the next class—viz., that for six plants, Mr. J. Stevenson, gardener to J. Sichel, Esq., Timperley, is first with two good specimen Allamandas—viz., cathartica and Hendersoni, Ixora princeps, which, though small is a mass of bloom, two Heaths, and Dipladenia acuminata. Mr. Bolton, Birstall Hall, is second with Allamanda Hendersoni in good bloom, and Hoya carnosa, which does not make a good exhibition plant, unless as a large specimen it can be placed on a high stage, so as to be viewed from a lower level.

The special prize offered by H. L. Micholls, Esq., for three fine-foliaged and three flowering plants, the latter to include two Ixoras, was awarded to Mrs. Cole & Sons, Withington, Manchester, who

exhibit Ixora Colei, with fine compact heads of white flowers; Ixora coccinea, fine; a handsome specimen of Erica Paxtoni, Crotons variegatum and angustifolium, and the variegated Aloe-leaved Yucca. Mr. Baines, Mr. Micholl's gardener, also sends a collection, consisting of fine specimens of Erica tricolor Holfordi, Ixora coccinea and aurantiaca; and of ornamental-foliaged plants a good example of Alocasia Lowii, Dicksonia antarctica, and Rhopala corcovadense.

Prizes were offered by Julius Sichel, Esq., for flowering and fine-foliaged plants, four of each. Mr. Brierley, gardener to J. Kendal, Esq., High Bank, Cheadle, who is first, has Alocasia metallica, a very fine specimen of Allamanda Hendersoni, Croton angustifolium, Sanseviera javanica, and Bougainvillea glabra, all of which are good. Mr. Cardwell, gardener to F. Hobson, Esq., Pownall Hall, Wilmslow, is second, likewise with a good collection, in which are fine plants of Alocasia metallica and Yucca filamentosa variegata; also Aërides Dayi and Dipladenia amabilis. Messrs. Bell & Thorpe, of Stratford-on-Avon, exhibit in their collection a small but very good specimen of Cissus discolor.

The prizes offered by E. Brooke, Esq., and L. Haumer, Esq., are well contested, Mr. Brierley being here also first; Theophrasta imperialis, Cordyline indivisa, Erica Candolleana, and Bongainvillea glabra being noticeable in this collection. Mr. Stevenson, gardener to J. Sichel, Esq., comes second with a very good specimen of Alocasia Jenningsii, and a fine one of A. metallica, an excellent Erica Fairrieana, Sanchezia nobilis variegata, Dipladenia amabilis, Pleroma elegans, and other plants less noteworthy. The special prize offered by H. L. Micholle, Esq., for ten fine-foliaged plants, is also taken by Mr. J. Stevenson with Stevensonia grandifolia, Theophrasta imperialis, a splendid specimen of Alocasia metallica, 5 feet in diameter, the variegated New Zealand Flax Dicksonia antarctica, Latania borbonica, Croton variegatum, and a Bonapartea.

Special prizes offered by the City of Manchester for miscellaneous plants, also brought excellent collections of stove and greenhouse plants, though not limited to them. Mr. W. Cardwell is first with a fine specimen of Alocasia Lowii, and good examples of Theophrasta imperialis, Cyathea medullaris, Erica ampullacea major, Erica Fairrieana, Dipladenia amabilis, Allamanda cathartica, and Cordyline australis. Mr. W. E. Dixon, who is second, has a fine Gleichenia speluncæ, Phœnocoma prolifera Barnesii, well covered with flowers, which are small, Ixora amboynensis, a very good Croton angustifolium, Dicksonia antarctica, with a large trunk, Ixora alba, a fine Vanda suavis, but the two spikes few-flowered, a fine Erica Parmentieriana rosea, and a fine pan of Anæctochilus Lowii. Mr. J. Shaw, Bowdon and Manchester, is third with Allamanda Hendersoni, Roulinia pitcarnifolia, with graceful leaves, 4 feet long, a handsome specimen of Croton variegatum, Yucca gloriosa angustifolia in flower, Yucca quadricolor, Eurya latifolia variegata, Phormium tenax variegatum, and Dracæna lineata. This is a very neat and effective collection.

In the general class, nine fine-foliaged plants, Mr. J. Bolton, gardener to W. Worswick, Esq., Leicester, takes a first prize, with a collection, the most noticeable of which are Croton angustifolium, Cissus discolor, fine; Seaforthia elegans, Pandanus elegantissimus, Croton variegatum, Yucca variegata, and Selaginella cæsia arborea. In the nurserymen's class, Mr. B. S. Williams takes the lead with an excellent collection, in which there are beautiful specimens of Cordyline indivisa, Crotons pictum and variegatum, Pandanus ornatus, a large and remarkably fine specimen of Dasylirion acrotrichum, Theophrasta imperialis, Yucca aloifolia variegata, and Cycas revoluta. Messrs. Felton & Son, Edgbaston, come second, having among others a fine specimen of Verschaffeltia splendida, Sanchezia nobilis variegata, Cordyline indivisa, and Crotons. Mr. J. Shaw is third with an excellent Agave filifera, a handsome plant of Yucca aloifolia variegata, Pandanus ornatus, Theophrasta imperialis, and other good plants. Mr. W. E. Dixon is fourth. In the amateurs' class for six, Mr. G. Elkins, gardener to T. H. Birley, Esq., M.P., is first, and Mr. Philips, gardener to A. Heywood, Esq., second.

For the special prizes offered by the proprietors of the "Florist and Pomologist," for the best four softwooded greenhouse plants, only one collection is staged, that from Messrs. Bell & Thorpe, who send a poor Plumbago capensis, Lantana mutabilis, and two Achimenes, one of which, Miss Earle, is a well-flowered plant.

Orchids.—Of these there is a fine display, though the number of competitors is not so great as we expected in such a great centre of Orchid culture as Manchester. The special prizes offered by Mrs. Mendel and W. C. Jones, Esq., respectively, were awarded to Mr. Archer, gardener to A. Turner, Esq., Leicester, and Mr. Swan, gardener to T. Jones, Esq., Whalley Range. The former has Phalænopsis grandiflora with three fine spikes, Aërides odoratum and affine, both fine, Cattleya superba, Aërides virens superbum, Cypripedium superbiens with eleven flowers, Aërides Lobbi with three branching racemes, Odontoglossum Reichenheimii, and Cattleya Leopoldi. Mr. Swan has Odontoglossum cordatum, Saccolabium Holfordii, Miltonia spectabilis, Epidendrum prismatocarpum with three spikes, Epidendrum vitellinum majus with large flowers, and Odontoglossum Alexandræ. Mr. R. Hitchmough, gardener to W. Agnew, Esq., Penzance, who takes a third prize, has a remarkably fine Saccolabium Blumei. Special prizes were also offered by Messrs. J. Brooke & Co., and W. Southern, Esq., for the best collection of six. These were awarded to Mr. E. Mitchell, gardener to Dr. Ainsworth, Cliff Point, Broughton, and Mr. Swan; the former has Miltonia Regnelli purpurea with four spikes, Aërides quinquevulnerum, and others; the latter, Odontoglossum Alexandræ with two fine spikes, O. Bluntii, and Aërides. In the general class for a collection of six, Mr. J. Orme, gardener to W. C. Bird, Esq., Kersal Moor, takes the first prize. Mr. Swan, who is second, has Saccolabium Blumei majus, Cypripedium Dayanum with two fine flowers, Miltonia Regnelli purpurea, Cattleya Regnelli, Odontoglossum Lindleyanum, and Aërides Lobbi with a slender spike upwards of 18 inches long. Mr. E. Mitchell, gardener to Dr. Ainsworth, is third with Miltonia spectabilis, having eighteen fine flowers, Aërides quinquevulnerum, Cattleya Leopoldi, Vanda tricolor, Aërides roseum superbum, and Saccolabium Blumei majus. Mr. McMillan, gardener to — Gotteschalk, Esq., and Mr. Allen, The Grange, Didsbury, also exhibit in this class. In that for nurserymen, Mr. Williams, of Holloway, is first with beautiful examples of Barkeria spectabilis, Cypripedium superbum with thirteen fine flowers, Aërides odoratum majus, Saccolabium Blumei majus, and Cattleya superba beautiful in colour. Mr. W. E. Dixon, of Beverley, is second, and has a good mass of Cypripedium Veitchii, Saccolabium præmorsum, and Aërides.

Ferns and Lycopods.—For four Exotic Ferns special prizes were offered by Mrs. Samuel Taylor, Didsbury, and by Messrs. Barber. Mr. Cardwell, gardener to T. Hobson, Esq., is first with Leptopteri superba, Cyathea Smithii, Brainea insignis, and a fine Gleichenias Mr. W. E. Dixon is second with Trichomanes radicans, fine, Gleichenia Mendeli, Davallia tenuifolia stricta, and Cyathea dealbata. Messrs. Bell & Thorpe also exhibit in this class. For nine Exotic Ferns (nurserymen), Mr. B. S. Williams is first with a tall and beautiful specimen of Gleichenia speluncæ, Todea africana, Cibotium princeps, Cyathea dealbata, Dicksonia antarctica with a tall trunk, Adiantum trapeziforme of a beautiful green, Cibotium Schiedei, and a golden Gymnogramma. Messrs. G. & W. Yates, Sale, Manchester, are second with neat plants of Adiantum trapeziforme and Sanctæ-Catharinæ, Lomaria gibba, Pteris cretica albo-lineata, &c. Mr. T. Stafford, The Hyde, Manchester, is third with good though not large specimens of Cyathea medullaris, Alsophila australis, and small specimens of others, of which Adiantum formosum is a beautiful little plant. In the amateurs' class for the same number, the first prize goes to Mr. J. Bolton for good healthy specimens of the Bird's-nest Fern, Adiantum trapeziforme, Stenochlæna scandens, Cibotium princeps, Adiantum cuneatum, Lomaria gibba, Adiantum formosum, and Blechnum corcovadense. Mr. Baines, who is second, has a fine plant of Davallia bullata, a large Gleichenia flabellata, G. speluncæ, very pretty, and Todea superba. Mr. C. Phillips, gardener to A. H. Heywood, Esq., is third.

Special prizes were offered by Mr. H. Crowe and Messrs. Barker Brothers, for twenty British Ferns. The first of these was awarded E. J. Lowe, Esq., of Highfield House, Notts, who sends among them Polystichum angulare Wakeleyanum, Adiantum capillus-Veneris, Osmunda regalis cristata Lowei, Scolopendrium vulgare crispum latum, which is a pleasing bright green form; Athyrium F.f. Monkmannii, Scolopendrium vulgare magnificum, Adiantum capillus-Veneris kalon, Lastrea rigida, Athyrium F.f. longridgense, Lastrea F.-mas phylloidenm, Asplenium mariuum, Polystichum angulare nidum, Lastrea pseudo-mas nitida and cristata, Lastrea F.-mas variegata, edged with pale yellow, but rather sickly-looking, and Lastrea dilatata. J. E. Mapplebeck, Esq., is second with Athyrium F.f. plumosum, Polypodium cambricum, Allosorus crispus, &c.

In the general class for twelve British Ferns, Mr. Mapplebeck is first, Mr. Rylance second, and Messrs. Stansfield, of Todmorden, third. Mr. Mapplebeck has, among others, charming examples of Polypodium alpestre, Athyrium F.f. Elworthii, A. F.f. coronatum, Lastrea pseudo-mas cristata, Osmunda regalis cristata, Polystichum angulare proliferum, Cystopteris fragilis sempervirens, Scolopendrium vulgare stenomenon, and Hymenophyllum tunbridgense. The best pair of tree Ferns are Dicksonia antarctica, from Mr. B. S. Williams, standing at least 9 feet high; the second best come from Mr. Shaw, of Manchester, and are about 6 feet high.

The best six Lycopods are exhibited by Mr. R. Fleming, Waterloo, Liverpool, and are trained on wires forming handsome cones about 4 feet high, from the bottom of the pans. The best are Selaginella macrophylla, dichotoma, Schotti, lævigata, and stolonifera. Mr. G. Elkin, gardener to T. H. Birley, Esq., M.P., is second; Mr. Price, third; Mr. Rylance, fourth.

Palms.—These are not very numerously shown, nor are the specimens so stately as we have seen at previous shows. The Manchester Botanical and Horticultural Society's prizes went to Mr. A. Williams, gardener to G. Broome, Esq., Fallowfield; and the second to Mr. W. E. Dixon, Beverley. Among these are good specimens of Stevensonia grandifolia, Thrinax elegans, Latania borbonica, Geonoma, and Verschaffeltia splendida. Mr. Shaw is first for the best six, and Messrs. G. & W. Yates second.

Dracænas.—These are not numerously shown; the best come from Mr. B. S. Williams, and comprise fine plants of D. lineata, cannæfolia, Veitchii, umbraculifera, atrosanguinea, and australis. Mr. Shaw is second; Messrs. G. & W. Yates third.

Trees and Shrubs.—Of these there are several highly interesting collections, containing many remarkably fine specimens, especially of the rarer Conifers, Messrs. Barron & Son, of Borrowash, take the first prize for twenty hardy Conifers, offered by T. Ashton, Esq., with a collection such as few but Mr. Barron could produce. Sciadopitys

verticillata, 6 feet high, Biota elegantissima, a beautiful golden Arbor-Vitæ; Cryptomeria elegans, Retinospora pisifera, Cupressus Lawsoniana, 10 feet high, a fine Araucaria imbricata, Arthrotaxus laxifolia, very free in growth and fine; Retinospora obtusa, and Larix Kæmpferi are especially worthy of attention. Mr. Shaw, who is second, taking the prize offered by H. K. Belstone, Esq., has among others a fine Araucaria, Thujopsis dolabrata variegata, Cryptomeria elegans, Thuja japonica, Cedrus deodara variegata, Retinospora pisifera. The best six Hollies, for which special prizes were offered by the Proprietors of the *Manchester Guardian*, come from Messrs. Barron & Son, and include several fine varieties; the second best are exhibited by Mr. Kellett. The prize for the best ten deciduous trees, offered by the Proprietors of the *Manchester Courier*, is taken by Mr. J. Shaw. Mr. Grimshaw's prizes for the best pair of standard Hollies also go to Mr. Shaw for Ilex aquifolium aureum, 8 feet high. The best pair of Golden Yews come from Messrs. Barron & Son; the second best from Mr. J. Shaw. The special prize offered by B. Whitworth, Esq., for the best pair of standard Bay trees, is taken by Mr. Williams with plants having heads nearly 5 feet in diameter, and standing about 8 feet high; the second prize by Mr. W. McMillan. For pyramidal Box trees Mr. Stubbs's prizes are taken by Mr. Shaw with a pair of the Variegated 9 feet high, and Mr. Stafford with a pair 7 feet 6 inches high. Mr. Williams also furnishes a handsome pair. Messrs. Standish & Co., Messrs. Lane & Sons, Messrs. Barron, Mr. Shaw, Messrs. Yates, and others furnish extensive collections, which well deserve more extended notice than our space will allow this week.

Fuchsias.—There are a number in pots, though the general quality of the plants is scarcely up to what might have been expected in such a district. In Class 56, for six Fuchsias in pots (amateurs), the first prize was withheld; the second prize being taken by Mr. T. Gresty, gardener to R. Voss, Esq., Fallowfield, with varieties scarcely worth mentioning. Strange to say, there is no competition in the nurserymen's class for the same number of plants, nor in the open class for three standard Fuchsias. The special prizes given by Messrs. J. Rylands and J. Shaw for eight Fuchsias brought some competition; Mr. R. Fleming, Sandheys, Liverpool, being a long way first with very well grown and bloomed plants, but having the fault of being trained in a severely formal pyramidal shape. The sorts were Tristram Shandy, Turban, very like the foregoing, and La Crinoline, dark varieties; Reine Cornelissen, a double white-corollaed variety; and Reine Blanche, Fair Oriana, Rose of Castille, and Mrs. Marshall, light varieties. Second, Mr. George Edward, York, with La Favourite, dark; Guiding Star, Rose of Castille, E. G. Henderson, Alba coccinea, light varieties: Vainqueur de Pacbla, double white corolla, and others. Mr. Woodland also exhibits, having plants of much the same style of growth as those of Mr. Fleming, but badly flowered.

Pelargoniums.—A very large number of Variegated Pelargoniums are staged, using the term in the broad sense of including all the types of variegation. The first of the special prizes offered to amateurs for six variegated Zonal Pelargoniums was taken by Mr. A. Tokingham, Wilmslow, with good plants of Sophia Dumaresque, Queen's Favourite, Mrs. Dix, Florence, Countess of Craven, and Princesse Clotilde. The plants are dull in colour, but this is clearly traceable to the recent hot weather. Mr. Smith, gardener to J. H. K. Balstone, Esq., is second with Italia Unita, Edwinia Fitzpatrick, Mrs. Dix, Sophia Cusack, very fine; Beauty of Guestwick, and Miss Watson. With the exception of Sophia Cusack these also were badly coloured. Mr. E. Bridge, gardener to S. Jorett, Esq., has Italia Unita, Sunset, Mrs. Pollock, Agnes, Lady Callum, and Queen's Favourite, and should have received an extra prize.

There were also open classes for six Variegated Zonal and six Variegated Pelargoniums. In the former Messrs. F. & A. Smith, Dulwich, London, are first with Princess Teck, finely coloured, Lady Callum, and Earl of Shafteshury, golden-edged varieties; and Impératrice Eugénie, Miss Burdett Coutts, and Banshee, silver-edged varieties. Mr. J. Tomkins, Sparkhill, Liverpool, is second with Lady Callum, Sophia Cusack, Beauty, Miss Tomkins, and Sophia Dumaresque, golden-edged varieties; and Italia Unita, silver-edged. Mr. J. Smith, gardener to J. K. Balstone, Esq., is third with large but dull-looking plants of Mrs. Pollock, Sophia Dumaresque, Lucy Grieve, Countess of Tyrconnel, Beauty of Guestwick, and Sunset. With six Variegated Pelargoniums Mr. J. Tomkins is first with Flower of Spring, Burning Bush, Silver Star, Stella Variegata, Oriana Improved, and Miss Kingsbury. Second, Messrs. G. & W. Yates with Sophia Dumaresque, Lady Callum, Sophia Cusack, Countess of Craven, Florence, finely coloured, and perhaps the best specimen Variegated Zonal Pelargonium in the whole Show, and Italia Unita. Third, Messrs. Bell & Thorpe with Italia Unita, Miss Kingsbury, L'Elegante, Argus, Flower of Spring, and Golden Chain. In addition, Messrs. F. & A. Smith stage a fine group of Variegated Pelargoniums, some seventy-two kinds. The following are very striking, being in good condition:—L'Empereur, Sunray, Louisa Smith, Sultan, and Coronet, golden-edged Variegated Zonals; Miss B. Coutts, Mabel Morris, Peri, Her Majesty, Queen Victoria, Impératrice Eugenie, Celestial, and Diamond, silver-edged varieties; and the following promising gold and bronze varieties—Criterion, Nobilis, Modèle, Golconda, and Distinction, a very promising dwarf-growing variety in the way of the Rev. W. F. Radclyffe, and apparently an improvement on it.

In the matter of large-flowering Pelargoniums, Manchester is much behind other districts unless it is past their best. In Class 59, with six kinds, Mr. Bridge, gardener to S. Jorrett, Esq., is first with Duc de Magenta, Madame Lemiche, Le Vesuve, Regina Formosa, Princess Clotilde, and Bessie, well-grown plants, mainly of the French spotted type, and poor in quality. Second, Mr. C. Rylance, Ormskirk, with Charles Turner, Mary Hoyle, Amy Robsart, King of the Belgians, Beacon, and Desdemona. Third, Mr. Fleming. Fancy kinds are very much better done, being both well grown and flowered, while the varieties are more in keeping with the times in which we live as compared with some of the large-flowering varieties. Messrs. Bridge and C. Rylance were placed first, the former having the largest plants, which was quite balanced by the superior quality of those of the latter. The former has Evening Star, Undine, Acme, Ellen Beck, Masjid, and Celestial. Mr. Rylance has Undine, Illuminator, Sweet Lucy, Evening Star, Godfrey Turner, and Duchess of Buccleuch. Mr. R. Fleming was placed second, with Roi des Fantaisies, Acme, Delicatum, Lady Hume Campbell, Illuminator, and Indispensable.

In the amateur's class, for six Zonal Pelargoniums, Mr. Bridge is first with capital plants of Madame Werle, Monsieur G. Nachet, Excellent, Mrs. W. Paul, Eugene Mézard, and Virgo Marie. Second, Mr. R. Fleming, with Amelina Grisau, Mrs. W. Paul, Rebecca, Madame Vaucher, Softness, and Eugène Mézard. In the nurserymen's class, Mr. C. Rylance is first with Magnum Bonum, Clipper, Eugène Mézard, Madame Schott, Coronet, and Prime Minister, fine and well-grown plants. Second, Messrs. Bell & Thorpe, and third, Messrs. G. & W. Yates.

In the open class for six Nosegay Pelargoniums, Mr. Bridge is again first, with Lord Palmerston, Duchess, Amy Hogg, Profusion, Baron Ricasoli, and Le Grand; well-grown and flowered plants. Second, Messrs. Bell & Thorpe, Stratford-on-Avon, with Black Dwarf, Le Grand, Amy Hogg, Indian Yellow, Rebecca, and Startler. Third, Mr. G. Edward, York, with Christine Nosegay, Rose Rendatler (?), Orange Nosegay, and others similar to the foregoing.

In the class for three double-flowering Pelargoniums the competition was somewhat spirited, six groups being staged. Messrs. Carter and Co., of Holborn and Sydenham, London, are first, with capital plants of Madame Lemoine, Gloire de Nancy, and Wilhelm Pfitzer, very well grown and flowered. Messrs. Standish & Co., Ascot, are second with Surrey, Marie Lemoine, Madame Lemoine, and Triumph. Third, Mr. G. Edward, York, with Capitaine L'Hermite, Gloire de Nancy, and Triomphe de Lorraine. Thomas Jones, Esq., of Manchester, also gave two special prizes for the best six Zonal Pelargoniums. The first of these was taken by Mr. E. Bridge, with excellent plants of Miss Martin, Beauté de Parterre, St. Fiacre, Amelina Grisan, Clipper, and Rose Rendatler; the second by Mr. Woodland, gardener to Major Blundell, Liverpool, with Mrs. W. Paul, Eblonissante, George Hock, Madame Vaucher, Amelina Grisan, and Duchess.

The classes for Lilium lancifolium did not fill, nor did either of the classes for Achimenes, or that for six Gloxinias. The first of the special prizes given by Sir James Watts for six pots of Lilium auratum is taken by Messrs. G. & W. Yates, Manchester, with some good plants. Dr. Ainsworth, Manchester, is second.

The classes for Herbaceous Phloxes brought but two collections, and the best appeared to be composed of plants that had been lifted from the open ground purposely for the show. The same can be said of the one group of six Pentstemons, and even then they were so bad that the Judges refrained from making any award.

Double and single Petunias in pots are represented, but only indifferently well; but there are no Delphiniums, nor Lobelias of the fulgens type; nor Antirrhinums, nor Pyrethrums.

Carnations and Picotees.—Cut blooms of these are not nearly so numerous as at Leicester last year, though one might have supposed that the Manchester district being to some extent the northern home of the Carnation and Picotee, these flowers would have been much more largely represented. In Classes 89, with twenty-four Carnations, and 90, with twenty-four Picotees, Mr. C. Turner, Slough, has grand flowers, and both in size and substance of the blooms, as well as in their fine colouring, so completely distanced the rival collections, as to be without the pale of comparison. Of the former he has Flora's Garland, William Cowper, Ridleman, Dreadnought, Prince Albert, Premier, Samuel Moreton, Anthony Dennis, Florence Nightingale, Nymph, Sportsman, Squire Trow, Princess Royal, Lord Ranclife, King John, Duke of York, Captain Stott, Eccentric Jack, Brutus, Merrimac, James Merryweather, Annihilator, Touchstone, and John Bayley. Mr. George Edward, York, is second, the best flowers being John Reet, Virid, Earl of Stamford, Mrs. Edward, Beauty, Napoleon, True Blue, Miss Lucy, Brilliant, Delicata, and Lord Ranclife. Of Picotees, Mr. Turner has very fine flowers of Admiration, a very beautiful new bright purple heavy-edged flower of fine quality; Lord Nelson, Mrs. Fisher, Prince of Wales, Amy Robsart, Green's Lord Nelson, Mrs. Fisher, Prince of Wales, Amy Robsart, Green's Queen, Charmer, Lucy, Col. Clerk, Bridesmaid, Mrs. Norman, Miss Queen, Charmer, Lucy, Col. Clerk, Bridesmaid, Mrs. Norman, Miss Drake, Lord Valentia, Ganymede, Miss Wood, Countess, Gipsy Drake, Lord Valentia, Ganymede, Miss Wood, Countess, Gipsy Queen, Picco, Miss Turner, Rev. H. Matthews, Forester, Flower of the Queen, Picco, Miss Turner, Rev. H. Matthews, Forester, Flower of the Day, a heavy rose-edged seedling in the way of Green's Queen, but darker, and another light-edged seedling flower. Mr. George Edward is second with some flowers of inferior quality. In the classes for amateur growers there was no competition. The first of the special prizes offered by Mr. Broome for twelve Carnations and Picotees, was also taken by Mr. Turner, who had of the former Captain Stott, King John, Dreadnought, Sportsman, Eccentric Jack, and Favourite: and of Picotees, Miss Turner, a pretty new medium light rose-edged

flower; Miss Drake, Lord Valentia, Admiration, Mrs. Norman, and Miss Wood. Second, Mr. George Edward. In the class for twelve Pinks, Mr. J. Mellor, Stamford Street, Ashton-under-Lyne, produced a stand of true northern flowers, each flower having been reduced to two circles of petals, which are very pure and exquisitely laced, but the flowers appear very unnatural notwithstanding. The varieties are John Ball, Emily, Robin Hood, Jane, Emma, Auricula, Earl Stamford, Defiance, Bertha, Champion, Arlette, and Unity. Two other collections were staged, but the Judges withheld any awards to them.

Verbenas.—With cut blooms Mr. C. J. Perry, Castle Bromwich, and Mr. C. Turner, were found in competition. The latter certainly has the biggest bunches, but the superb quality of Mr. Perry's flowers gained the first prize. They are—Shakespeare, Model, Géant des Batailles, Edwin Day, rich bright orange scarlet; Annie, Lord Leigh, Butterfly, a beautiful new variety, blush, with crimson centre; Joseph Sanders, rich crimson, with lemon eye; Mrs. Reynolds Hole, and Rising Sun, glowing salmon red, with small white eye surrounded by a rich deep maroon ring, one of the most striking varieties Mr. Perry has ever raised. Differing from these, in Mr. Turner's stand, who was awarded the second prize, are King of Verbenas, Leah, Nemesis, J. C. Ward, Samuel Moreton, John Wilson, Foxhunter, and Chastity. Mr. Turner also contributes an extra stand of fine bunches.

With cut blooms of Zonal Pelargoniums, of which a great many are staged, Mr. C. Phillips, gardener to A. H. Heywood, Esq., Sedgley Park, Prestwich, is first with Clipper, President Reveil, Amy Hogg, Lord Palmerston, Provost, Le Grand, Striking, a good salmon-coloured variety; Rose Rendatler, Mrs. W. Punl, Hector, a pink-flowering variety; Beaute de Suresnes, and Madame Vaneher. Second, Mr. C. J. Perry, Castle Bromwich, with Mons. G. Nachet, Clipper, Beauty, Striking, Roi d'Italie, Vesuvius, La Perouse, a hybrid Nosegay; Model, Emeline Grisau, Madame Werle, Madame Vancher, and Beauté de Suresnes. Third, Mr. W. Cunningham, Burton-on-Trent.

Cut Roses are a grand feature, and make a charming display along the south side of the fruit tent. In the nurserymen's class for forty-eight varieties Mr. J. Cranston, Hereford, is first with some splendid blooms of the following Hybrid Perpetuals:—Alfred Colomb, Alice Durean, Antoine Ducher, Beauty of Waltham, Caroline de Sansal, Charles Lefebvre, Claude Million, Comte de Nanteuil, Comtesse de Chabrillant, Dr. Andry, Duc de Rohan, Duc de Wellington, Duchesse de Caylus, Felix Genero, Fisher Holmes, Horace Vernet, Joseph Fiala, Josephine de Beauharnais, La Duchesse de Morny, La France, Lælia, Laurent Descourt, Leopold I., Lord Herbert, Lord Macaulay, Madame la Baronne de Rothschild, Madame Boutin, Madame Charles Crapelet, Madame Charles Verdier, Madame Charles Wood, Madame Furtado, Madame Victor Verdier, Madame William Paul, Mdlle. Marguerite Dombrain, Maréchal Vaillant, Marguerite de St. Amand, Maurice Bernardin, Paul Verdier, Pierre Notting, Prince Camille de Rohan, Prince Henri des Pays Bas, Reine du Midi, Sophie Coquerelle, and Xavier Olibo: and the following Tea Roses—Gloire de Dijon, La Boule d'Or, Maréchal Niel, and Madame Margottin. Second, Mr. C. Turner, having fine examples of Madame C. Joigneaux, Gabriel de Peyronny, Madame George Paul, King's Acre, Marie Baumann, La Duchesse de Morny, Prince of Wales, Beauty of Waltham, Mdlle. Annie Wood, Lord Herbert, Charles Rouillard, Alfred Colomb, Madame Vidot, and Prince Camille de Rohan; Baron Gonella, Hybrid Bourbon; and the following Tea Roses, Madame Willermoz and Alba Rosea. Third, Messrs. S. Perkins & Son, Coventry.

In the amateurs' class for the same number, the Rev. S. Reynolds Hole, Caunton Manor, Newark, is first with a very fine lot of flowers, consisting of Maréchal Vaillant, Comte de Nantenil, Antoine Ducher, Miss Ingram, Madame Victor Verdier, Madame Furtado, Black Prince, Madame Caillat, Gloire de Santenay, Mons. Noman, Mdlle. A. Wood, Maréchal Niel, Dr. Andry, Madame Vidot, Senateur Vaisse, Caroline de Sansal, Vicomte Vigier, Gloire de Dijon, Maurice Bernardin, Madame C. Joigneaux, Lord Raglan, Princess Mary of Cambridge, Abbé Berleze, Centifolia rosea, Leopold I., Charles Rouillard, Laurent Descourt, Madame Bravy, Charles Wood, Exposition de Brie, Madame Charles Crapelet, Comtesse de Chabrillant, Madame Hector Jacquin, Charles Margottin, Alfred Colomb, Madame Rivers, John Hopper, Marguerite de St. Amand, Prince Henri des Pays Bas, Lord Herbert, Marie Baumann, Auguste Mie, and others which had lost their labels. Mr. J. C. Perry, Castle Bromwich, is second, with fine flowers of the following, among others, Senateur Vaisse, Horace Vernet, Alpaide de Rotalier, Baronne de Noirmont, Leopold I., Lord Clyde, Auguste Mie, Pierre Notting, Madame Rival, Xavier Olibo, Charles Lefebvre, Beauty of Waltham, Gloire de Vitry, Baron Gonella, and La Reine. Third, Mr. Draycott, gardener to T. T. Paget, Esq., Humberstone, near Leicester. The Rev. Mr. Hole is also first in Classes 98, 99, and 100, in the former with twenty-four varieties—viz., Black Prince, Madame Furtado, Maréchal Vaillant, La Tour de Crouy, Leopold I., Anna de Diesbach, Charles Lefebvre, John Hopper, Duc de Rohan, Marguerite de St. Amaud, Mdlle. Marie Rady, Maréchal Niel, Lord Raglan, Madame Knorr, Alfred Colomb, Charles Ronillard, Prince Henri des Pays Bas, Triomphe de Rennes, Vicomte Vigier, Miss Ingram, Madame Clemence Joigneaux, Pierre Notting, Monsieur Noman, and Comte de Nanteuil. Second, Mr. C. J. Perry; the best flowers being La France, Alice Dureau, Jules Margottin, Madame Fillion, Semiramis, Comte de Nanteuil, and François Lacharme. The twelve shown by Mr. Hole contain Black Paince, Maréchal Niel, Maréchal Vaillant, Madame Bravy, Lord Herbert, Comtesse de Chabrillant, Charles Lefebvre, Madame Furtado, Leopold I., Madame Vidot Vicomte Vigier, and Mons. Noman. Mr. C. J. Perry comes again second, and has among others good blooms of Beauty of Waltham, Maréchal Niel, Horace Vernet, and Général Jacqueminot. The Rev. Mr. Hole's six consist of Charles Lefebvre, Maréchal Niel, Alfred Colomb, Maréchal Valliant, La Duchesse de Morny, and Dr. Ardry. Second, Mr. Draycott; and third, J. E. Mapplebeck, Esq.

Class 101 was for twelve new Roses sent out in 1866, 1867, or 1868. Mr. J. Cranston, Hereford, was first, with good examples of Monsieur Noman, President Willermoz, Horace Vernet, Napoleon I., La France, and Duchesse d'Aoste, Hybrid Perpetuals; and the following Bourbon and Tea Roses—Miss Ingram, Madame Margottin, Monsieur Furtado, Madame Marie Circdle, President Willermoz, Souvenir de Mons. Boll, La France, Duchesse d'Aoste, Madame La Baronne de Rothschild, Paul Verdier, Horace Vernet, very fine; Imperatrice Charlotte, Antoine Ducher, and Mrs. Ward, all Hybrid Perpetuals, and Jean Sisley, a fine new Tea Rose. Second, Mr. C. Turner, with Comtesse de Jancourt, Mrs. John Berners, President Willermoz, Monsieur Noman, Horace Vernet, Napoleon I., La France, and Duchesse d'Aoste, Hybrid Perpetuals; Miss Ingram, Hybrid Bourbon; and Madame Margottin, Monsieur Furtado, and Clotilde, Tea-scented varieties. Third, Messrs. S. Perkins and Son.

The first of the special prizes given by Edward Joynson, Esq., for eighteen cut Roses (amateurs), was also taken by the Rev. S. R. Hole, who has fine blooms of Victor Verdier, Maréchal Valliant, Triomphe de Rennes, Prince Camille de Rohan, Comtesse de Chabrillant, Black Prince, Devoniensis, Leopold I., Charles Rouillard, Madame Victor Verdier, Marechal Niel, Dr. Andry, Madame Thérèse Levet, Madame C. Joigneaux, Louise Magnan, Madame Hector Jacquin, Duc de Rohan, Monsieur de Montigny, &c. Second, Mr. Thomas Draycott. Third, Mr. C. J. Perry.

In addition to these, Messrs. Cranston, Paul & Son, W Paul, and others staged large groups of cut Roses, making a fine addition to the Show, and Mr. W. Paul also has a lot of cut Zonal Pelargoniums.

New Plants and Miscellaneous.—The special prize given by Messrs. T. Agnew & Son for the best six new plants is taken by Messrs. Veitch with Davallia Moorei, a very elegant Fern, Dracæna albicans, Croton undulatum, a handsome kind, the fine Alocasia Sedeni, and Crotons maximum and albicans. The same firm also furnish a very extensive and fine collection, in which we remarked Anæctochilus Lowii, Gymnostachyum Pearcei, Maranta tubispatha, several fine new Crotons, a magnificent Nepenthes Rafflesiana with immense pitchers, Dendrobium Bensoniæ, Iresine Lindeni, and Iresine metallica, which if hardy enough will be beautiful for bedding; Dendrobium crystallinum, beautifully tipped with lilac; D. Bensoniæ, the handsome Ficus Porteana, and a host of others. Mr. B. S. Williams is second with a numerous collection, in which are Geonoma Seemanni, which will be one of the handsomest of Palms for dinner-table decoration, Odontoglossum Schlieperianum, with yellow flowers, Iresine Lindeni, Dieffenbachia Walhsii, Thrinax grandis, a handsome Palm, Phajus albus, white, with a lilac-streaked lip, Maranta tubispatha, and many others. Mr. J. Denton exhibits a very beautifully executed basket of artificial flowers in a case, and Mr. Kayes, of Wilmslew, skeletonised leaves and seed vessels, which are highly creditable. Mr. Denton was awarded a first prize, Mr. Kayes an extra prize. Mr. Robson, of Linton Park, has a large euseful of cones of various Coniferæ, which was a very interesting and pretty exhibition. Among the cones shown were those of Araucaria imbricata, Pinus insignis, Picea cephalonica, P. nobilis, P. Webbiana, Cupressus Lambertiana, Cryptomeria Lobbii and japouica, Retinosporus, Cupressus Corneyana, Wellingtonia gigantea, Abies Menziesii, Cupressus funebris, Abies Morinda, and Pinus macrocarpa. Mr. J. E. Mapplebeck and E. J. Lowe, Esq., send large collections of various forms of British Ferns, mostly new. Messrs. Stansfield have also an interesting collection. A few new plants were also submitted to the Floral Committee. These and some further remarks, however, must be deferred till next week.

FRUIT AND VEGETABLES.

The show of Fruit is, on the whole, good. Although not particularly extensive, it is possessed of many points of special importance. One of the most striking features is the very fine collection of fruiting Figs in pots exhibited by the Royal Horticultural Society itself, from Chiswick. It may be said, and with truth, that never before has such an exhibition of Figs been seen at any place, and we are glad to see the endeavours of the Society in popularising the cultivation of this fruit.

Mr. Meredith, of The Vineyard, Garston, Liverpool, exhibits some magnificent examples of Vines grown in pots:—Muscat of Alexandria bearing large and fine bunches, and young Vines for next year's fruiting, all grown, as stated on the card, by the aid of Meredith's Vine manure. Messrs. Lane & Sons, The Nurseries, Berkhampstead, send also some fine specimens of pot Vines and orchard-house trees; the former heavily cropped and excellent.

In Class 2, for the cup offered by the Proprietors of the *Gardeners' Chronicle*, for the best collection of Fruits and Vegetables, Mr. Pottle, gardener to B. D. Colvin, Esq., Bealings Grove, Woodbridge, Suffolk, carries off the first honours, and very worthily so. The collection includes very fine Black Hamburgh Grapes well coloured, two fine Melons, Frogmore Pine Strawberries, Black Circassian Cherries, French Crab Apples, Ipswich Standard Cucumbers, Laxton's Supreme

Peas, very fine, Merriott Scarlet Carrots, White Spanish Onions, Globe Artichokes, Johnson's Wonderful Beans, Prince Teck Potatoes, White Stone Turnips; every article being of the highest possible quality. Mr. Tillery, gardener to the Duke of Portland, Welbeck, shows very good Buckland Sweetwater Grapes, large Napoleon Cherries, two fine Melons, Peas, Turnips, Kidney Beans, &c. Mr. Freeman, gardener to Lord Derby, Knowsley Park, Liverpool, shows in his collection very good Black Hamburgh Grapes, Black Tartarian Cherries, two Melons, one big and the other very little, Cucumbers, very excellent Early London Cauliflowers. This collection occupied the second place. Mr. Dennis, gardener to R. H. Ainsworth, Esq., Moss Bank, Bolton, also exhibits.

Class 3 is for the prizes offered by THE JOURNAL OF HORTICULTURE—viz., two first prizes, value £10 10s., for the two best desserts, consisting of not less than seven kinds of fruits of 1869, arranged as for the dinner-table, combining quality of fruit with taste of arrangement. Mr. Carmichael, gardener to the Prince of Wales, was for the third time placed first, and if in former seasons he has shown creditably, this season he has far eclipsed his former efforts. It is not saying too much when we say that it is the most worthily awarded prize in the Exhibition. The collection contains two splendid dishes of Black Hamburgh Grapes, a little rubbing being their only fault; a dish of Muscat Champion Grapes, with berries of enormous size and most excellent flavour—it is of a grizzly character, and although sent out some years ago, we have never met with it in such fine condition; one dish of White Grapes; two Melons, Scarlet Gem and Gordon Castle; four dishes of Stirling Castle Peaches, of medium size, but beautifully ripe and good; two dishes of Violette Hâtive and Murrey Nectarines, very highly coloured; May Duke Cherries; one Prickly Cayenne, and one Queen Pine Apple, and two dishes of very good Strawberries. The other prize was awarded to Mr. J. Wallis, gardener to J. Dixon, Esq., Astle Park, Congleton, but his collection can in no way compare with Mr. Carmichael's, and we think the two should not, therefore, have been placed on an equality. It contains a very good dish of Barrington Peaches, and very good Black Hamburgh Grapes, two dishes of Cherries, Nectarines, Chasselas Musqué Grapes, a very small Pine Apple, Strawberries, and Apples.

In class 5, ten dishes of fruit of eight distinct varieties, the first prize a silver cup, value £10 10s., was offered by the Mayor of Manchester; the second prize, by Mr. Peter Bailey, Heaton Mersey, a silver cup, value £5 5s. The best exhibition in this class comes from Mr. Stevens, gardener to his Grace the Duke of Sutherland, Trentham, but through not having been entered in time, were not for competition. It consisted of two very excellent dishes of Black Hamburgh Grapes, with large berries, and most beautifully coloured, one dish each of Jefferson and Kirke's Plum, very fine Brown Turkey Figs, four Trentham Hybrid Melons, two excellent Pine Apples, Noblesse and Royal George Peaches, Hunt's Tawny and Brugnon Nectarines. It seemed a pity to see such a splendid collection passed over. The first prize was awarded to Mr. Miles, gardener to Lord Carrington, Wycombe Abbey, Bucks, who exhibits a good Providence and Ripley Queen Pine, Black Hamburgh and Muscat Grapes, the latter not ripe, very good Bigarreau Napoleon and Black Tartarian Cherries, a fine dish of Dr. Hogg Strawberries, good Elruge Nectarines, Royal George Peaches, and two fine Melons. The second prize was awarded to Mr. W. S. Dobson, 19, St. James's Street, London. This was very effectively staged on pretty glass plates on tall stems. It contains very good Black Hamburgh and Muscat of Alexandria Grapes, a good Smooth Cayenne Pine, good Royal George Peaches, Elruge Nectarine, &c., Mr. Wallis, gardener to J. Dixon, Esq., Astle Park, Congleton also exhibits a very good collection.

Class 7, six dishes of fruit, distinct, first prize by Lady Watts, £6 6s.; second prize by ditto, £4 4s. This is very worthily awarded to Mr. Simpson, gardener to Lord Wharncliffe, Wortley Hall, who here exhibits one of the finest Queen Pines in the Show, very good Black Hamburgh and Muscat Grapes, a good dish of Nectarines, small but excellent Peaches, and Heckfield Hybrid Melons. The second prize falls to Mr. Wallis, gardener to J. Thompson, Esq., Kirby Hall, York, who exhibits very fine Black Hamburgh Grapes, just a little wanting in colour, good Noblesse Peaches, Violette Hâtive Nectarines, Brown Turkey Figs, British Queen Strawberries, and Heckfield Hybrid Melons. Mr. Webley, gardener to W. Jackson, Esq., Manor House, Birkenhead, shows an excellent lot, including splendid Black Hamburgh and Buckland Sweetwater Grapes, Royal George Peaches, Nectarines, Melons, and Cherries. Mr. Janson, gardener to T. Statter, Esq., Stand Hall, Manchester, likewise exhibits.

Class 22, six bunches of Grapes Black and White, first prize by Mr. Thomas Baines, Bowdon, silver cup value £5 5s.; second prize by Messrs. Johnson & Fildes, £2 12s. 6d. The first prize was awarded to Mr. Freeman, gardener to Lord Derby, for very good examples of Black Hamburgh and Muscat of Alexandria; the second to Mr. Janson for Black Hamburgh and Canon Hall Muscat, the latter not nearly ripe. Mr. J. Roberts, gardener to the Hon. Major Barry, Charleville Forest, Tullamore, Ireland, exhibits very large but badly coloured bunches of Black Hamburghs and Muscats. Mr. Farquharson, Acton Park Gardens, Wrexham, shows Black Hamburgh and Buckland Sweetwater. Mr. Cardwell, gardener to T. Dobson, Esq., Pownall Hall, Wilmslow, Cheshire, shows Frankenthal under the name of Mill Hill, Black Hamburgh, Muscat of Alexandria, and White Frontignan. Mr. Whittaker, gardener to Lord Crewe, shows Buckland Sweetwater and Black Hamburgh.

Class 43, six bunches of Black Hamburgh Grapes; first prize, £2 10s.; second, £1 10s.; third, £1 5s. all offered by Messrs. W. G. Galloway & Co. This was a well-contested class, and the first prize fell to Mr. Wooley for twenty splendid examples, perfect in every sense. The second prize went to Mr. W. Jones, gardener to S. K. Mainwaring, Esq., Oteley Park, Ellesmere, also very fine. Mr. Freeman, Knowsley, is third. Mr. Hill, Keele Hall, shows small but well-finished fruit. Mr. Wallis, gardener to S. Thompson, Esq., Kirby Hall, York, has very fair examples, wanting in colour. Mr. Chambers, Shirley, Birmingham, Mr. Janson, and Mr. Broadrett, gardener to E. Boden, Esq., Bowden, also exhibit.

In Class 17, for two bunches of White Grapes, the prizes were offered by James Collins, Esq. The first prize is awarded to Mr. Janson for Muscats; the second to Mr. Freeman for the same. Mr. Hill shows Buckland Sweetwater, Mr. Cardwell very good Muscats; Mr. Wallis, Astle Park, Foster's White Seedling.

Class 25, for six Pine Apples: first prize offered by Messrs. Armitage & Rigby, £5 5s.; second and third prizes by Abraham Haworth, Esq., £3 3s. and £2 2s. respectively. The first prize was awarded to Mr. Smith, gardener to H. Walker, Esq., Calderstone, near Liverpool, for six fine, clean, and even Ripley Queens. Second prize to Mr. Ward, gardener to T. N. Miller, Esq., Bishop Stortford, for one fine Queen, weighing 5¼ lbs., three Smooth Cayennes, respectively 6¾ lbs., 7 lbs., and 7¼ lbs.; one Prickly Cayenne, 6¼ lbs., and one Black Prince, which being a little gone disqualified the collection from taking the first prize, which they would otherwise have done. Third, to Mr. Simpson, Wortley Hall, for six small but nice fruit of Ripley Queen. Mr. Hepper, gardener to J. B. Walmsley, Esq., The Elms, Acton, W., sends six good-sized Queens, very much out of condition however. Mr. J. Denvill, gardener to Major Martin, Wooten Hall, Ashbourne, and Mr. Clarke, Panshanger Park, Hertford, also exhibit.

Class 31, one Pine Apple, any variety; first prize by Richard Haworth, Esq., £2 2s.; second prize by Arthur H. Heywood, Esq., £1 1. First prize awarded to Mr. Ward, for a splendid Queen weighing 6 lbs. Second prize to Mr. Clarke, Panshanger, for a Prickly Cayenne, which was not much more than half ripe.

Class 21, one dish of Peaches and one dish of Nectarines; prizes offered by Charles Durham, Esq., £3 3s. and £2 2s. respectively. First prize awarded to Mr. Tillery, Welbeck, for very fine Galande Peaches and Elruge Nectarines. Second prize, to Mr. Wallis, Astle Park, for good Barrington Peaches and Red Roman Nectarines. Mr. G. Morris, gardener to G. Oliver, Esq., Wood Hayes Park, Sale, near Manchester, shows very fine Royal George Peaches and Elruge Nectarines. Mr. James, gardener to the Duke of Leinster, Carton, Maynooth, and Mr. Norbury, gardener to W. McKenzie, Esq., The Priory, Bowdon, also exhibit.

Class 110, collection of fruit, eight dishes, six kinds. The best exhibition in this class comes from Mr. Miles, gardener to Lord Carrington, but which by some oversight only contained seven dishes instead of eight, had to be disqualified. The first prize was awarded to Mr. Simpson, Wortley Hall, who sends very good Grapes, Black and White, two small Pines, Peaches, Nectarines, Figs, and Melons. Mr. Miller, gardener to Lord Foley, Worksop Manor, was awarded the second prize, and his collection consists of fine Peaches, Black and White Cherries, good Black Hamburgh Grapes, and Foster's White Seedling, Figs, Nectarines, &c.

Class 111, Pine Apples, any variety. The first prize went to Mr. Ward for a fine Smooth Cayenne, weighing upwards of 6¼ lbs. Second, Mr. Denvill, for a Providence. Third, Mr. Chambers, Old Shirley.

Class 112, Grapes, Black, single dish. The first prize was awardde to Mr. Jones, gardener to S. K. Mainwaring, Esq., Oteley Park, Ellesmere, for fine examples of Black Hamburgh, very perfect in bunch and berry. Second, Mr. Woolley, for nearly equally fine examples, more regular in bunch, but not quite so large. Third, Mr. M. C. Watkins, Holmer Park, Hereford, for very large and well-coloured but sprawling bunches of Gros Guillaume. Messrs. Lane & Sons show good examples of Alicante, and Mr. Chambers large bunches of Black Hamburgh. Mr. Pottle, Mr. Smith, and Mr. Wallis also exhibit.

Class 113, White Grapes. This is altogether a poor display. The finest example is the Muscat of Alexandria from Messrs. Lane and Sons. One bunch is, however, rather green, and on that account was passed over by the Judges, and the first prize awarded to Mr. Wallis, Astle Park, for Foster's White Seedling. Second to Mr. Hill for the same. Third to Mr. J. Bolton for much over-ripe Buckland Sweetwater.

Class 114, Peaches. The first prize was awarded to Mr. A. Hay, gardener to Mrs. Holland, Sandway House, Altrincham, for magnificent examples of Royal George; the second prize to Mr. R. H. Smith, Calderstone, for beautiful Bellegarde; the third to Mr. Tillery for Galande. There are numerous exhibitors in this class, and many excellent dishes of fruit.

In Class 115, Nectarines, the first prize was awarded to Mr. Carmichael, gardener to H.R.H. the Prince of Wales, for a truly splendid dish of Violette Hâtive. Mr. Tillery, Welbeck, was placed second for, the same kind; and Mr. Turner, The Royal Nurseries, Slough, third for fine examples of Hunt's Tawny.

In Class 117, Figs, Mr. Freeman, Knowsley, is first for Brown

Turkey; Mr. J. Malcolm, Cholmondley Castle, Nantwich, second for Brown Turkey; Mr. Simpson third.

Class 118, Cherries, the first prize went to Mr. Tillery for a good dish of Bigarreau; the second to Mr. Goldsmith, gardener to Sir W. Farquhar, Bart., Polesden; the third to Mr. Smith, Calderstone.

In Class 119, Strawberries, four dishes distinct, there are sixteen competitors. The first prize was awarded to Mr. Farquharson, Acton Park Gardens, for President; second to Mr. R. S. Yates, nurseryman, Sale, for Lucas; the third to Mr. Hulme, for very fine Myatt's Surprise.

In Class 120, Strawberries, single dish, there are eleven competitors. First prize to Mr. J. Fowler, gardener to the Earl of Harewood, Leeds, for a very large and fine dish of President. Second to Mr. Farquharson, for Sir C. Napier. Third to Mr. J. Hulme, Timperley, Cheshire, for Myatt's Eleanor.

Class 121, Melon, Green-fleshed. The first prize was awarded to Mr. Webster, gardener to T. L. Behrens, Esq., Glyngarth, Bangor, for Golden Queen; the second to Mr. C. Frisby, gardener, Blankney Hall, Sleaford, for Brombam Hall; the third to Mr. Turner, Royal Nurseries, Slough.

In Class 122, Melons, Scarlet-fleshed, there are fourteen competitors. The first prize is taken by Mr. James, gardener to the Duke of Leinster, Maynooth, for Scarlet Perfection; the second by Mr. Clark, gardener to J. C. Brown, Esq., Holmbush House, Horsham, Sussex, for Clarke's Hybrid; the third by Mr. J. Bolton, gardener to W. Worswick, Esq., Birstall Hall, Leicester.

In Class 123, Plums, single dish, the first prize is awarded to Mr. Janson, Stand Hall, for Goliath; the second to Mr. Whitworth, gardener to J. Galloway, Esq., Stamford Bridge, Bowden, for Prince of Wales.

In Class 124, basket of out-door fruits, four distinct kinds, the first prize went to Mr. Deavill for Raspberries, Strawberries, Cherries, and Currants; the second to Mr. Hill, gardener to W. Tipping, Esq., Bald Hall, St. Helens, for a similar collection; the third to Mr. G. Elkins, gardener to F. H. Birley, Esq., Hart Hill, Pendleton, for Red and Black Currants, Cherries, and Raspberries.

In the Miscellaneous Class for fruits not mentioned in the schedule, Mr. Thomson, gardener to the Duke of Buccleuch, Dalkeith, shows a bunch of each of the following kinds of Grapes:—Black Hamburgh, Alicante, Chasselas Napoleon, Royal Muscadine, Grizzly Frontignan, Reeves's Muscadine, Royal Ascot, and a splendid bunch of his superb seedling Grape the Golden Champion, which, although not ripe, served to show its extraordinary properties and high merit. For this exhibition a special certificate was awarded. Messrs. Standish exhibit a fine boxful of Royal Ascot, which fully maintains its high prestige. Messrs. Lane & Son exhibit several varieties of Grapes in fine condition. Mr. Henderson shows his new Grape, which greatly resembles the Black Morocco, although quite distinct. Mr. Ingram, Belvoir, shows a collection of fifteen varieties of Strawberries in first-rate condition. Mr. J. Robson, gardener to Viscount Holmesdale, shows a most splendid basket of home-grown Oranges, Citrons, Loquats, &c., for which he was awarded a special certificate. Mr. Deavill shows a splendid specimen of Black Alicante Vine in a pot, bearing six fine bunches.

The remainder of the vegetables and other miscellaneous matters, for which we have no space this week, will be noticed in our next issue.

VICOMTESSE HÉRICART DE THURY STRAWBERRY.

Assuming that the above and the Prince Imperial are the same, I may observe that I tested the latter carefully this year, both under glass and in the open ground, side by side, with Keens' Seedling. Admitting that it is quite as early, more even in size, and firmer in flesh than Keens', it always proved deficient in sweetness; so much so, that I purpose adhering to Keens'.

For home consumption, where large quantities are required by persons whose palate is not highly educated, I recommend Empress Eugénie; for fastidious tastes, the British Queen, Rivers' Eliza, and Myatt's Filbert Pine. To these, as a late variety, not to be eaten till almost black, the old Downton, somewhat acidulated, perhaps, but very rich, should be added.—G. S.

DWARF APPLE TREES.

I have always felt some interest in the cultivation of Apple trees grafted on the sorts of stocks that dwarf them and make them fit for small gardens, and so about fourteen or fifteen years ago I made a small plantation of dwarf trees, some of which were grafted on Doucin and English Paradise stocks (between which there seems little difference, at least with some of them), and others on the French Paradise, which makes very dwarf trees. In the course of last winter or spring, much was said respecting the nature of Apple stocks. There was nothing new advanced, but my attention was called to my dwarf trees, and I made the following notes of the height and state of health of my trees growing in a soil very deep, cold, and retentive of moisture. Those marked "E. P." are grafted on English Paradise and Doucin stocks; those marked "F. P." on French Paradise stocks. All the trees are full of fruit.

Perle d'Angleterre, F.P. 2 feet. Healthy.	Flower of Kent, E.P. 3 feet. Cankered.
Reinette Grise de Champagne, F.P. 1 foot. Healthy.	Pauline de Vigny, F.P. 1 foot. Cankered.
Court-pendu Gris, F.P. 1½ foot. Healthy.	Reinette Jaune Hâtive, F.P. 2½ feet. Healthy.
Claygate Pearmain, E.P. 3 feet. Healthy.	Ribston Pippin, E.P. 2 feet. Cankered.
Golden Russet, E.P. 3 feet. Healthy.	Dutch Codlin, E.P. 2 feet. Healthy.
Emperor Napoleon, F.P. 2 feet. Cankered.	Summer Pippin, E.P. 3 feet. Healthy.
Empress Eugénie, F.P. 2 feet. Cankered.	Pearson's Plate, E.P. 4 feet. Healthy.
Reinette Dorse, F.P. 1½ foot. Cankered.	Guernsey Pippin, E.P. 3 feet. Healthy.
Reinette d'Angleterre, F.P. 2½ feet. Healthy.	

These trees have been occasionally removed, so that their growth has been checked. All of them are most prolific. It will be seen that the French Paradise stock retains its well-known character of being very dwarf.

I have been led into a notice of my trees by reading in one of our newspapers Mr. W. Robinson's, to a certain extent, erroneous opinion, that the French Paradise stock "suits well the stiff loamy and wet soils" hostile to fruit culture in England. In France this practice is carried out, and stiff cold soils chosen, otherwise the roots of the trees, being so near the surface, would be scorched by the fierce sun of France, and laid bare by the violent storms of summer. In England, if we wish to succeed in cultivating Apple trees on the French Paradise stock, we must entirely reverse the French practice, and plant them in rich generous soils rather dry than wet. But the question is, Do we require Apple trees for our gardens grafted on a foreign stock? I think not, if we may believe our eyes. Mr. Rivers, of Sawbridgeworth, exhibited some Apple trees at South Kensington on July 6th, not averaging more than 18 inches high, all full of fruit and clean and healthy—no canker to be seen. Mr. Rivers tells me that he cultivates from ten to twelve acres of these little trees, so well adapted for suburban gardens, and that upwards of 100,000 are sold each season, the demand increasing and the price decreasing annually. They are not sold as bush trees till they are from two to five years old, when they bear the first year after planting. As cordons, for which they are better adapted than the French Paradise stock, they are sold when one and two years old; but the very pretty bush-like trees exhibited by Mr. Rivers are more popular than cordons, requiring no wires, and but little trouble.—Pyrus Malus.

CULTIVATION OF QUEEN ANNE'S POCKET MELON.

Nothing has surprised me more than to hear that many persons have failed in the culture of this Melon; and some of them so much as not to bring a single fruit to perfection for two seasons. This is far from satisfactory, especially as it applies to what I consider to be one of the hardiest and most prolific Melons in cultivation. I am called upon to grow it largely here, not only to supply a handsome dish for dessert through the autumn months, but also for preserving whole, which if done properly, preserves for the Melons their handsome markings of orange and green, and when laid up in dishes in numbers of seven, nine, or eleven, gives them an appearance unequalled by any other kind of preserved fruit. In their preserved state the fruit is delicious, but in any other way the flavour is very inferior. I have been requested to detail my course of treatment, which I most willingly do, and shall be pleased if through my remarks the above difficulty is overcome.

By the time this appears in print, sow sufficient seed for an autumn crop; I advise as a more expeditious plan putting the seeds three in a 3-inch pot, using as many as are required for the crop; place them in a gentle heat—it is not necessary this should be artificial—though that from manure will assist them to vegetate. When the plants are sufficiently grown to show the third leaf, take away the two weakest plants, and grow the others on in pots till the fourth or fifth leaf appears. Then

plant them in a one, two, or three-light frame, according to the crop required, placing it where it may receive sunshine early and late; place the frame on the bare ground. A gentle bottom heat will start the plants well, though I generally grow them without this, raising the plants to within a foot of the glass by rough material placed below the soil. A moderately rich loamy soil not very light, 1 foot in depth, is what I find them thrive in. A three-light frame will take six plants; some would plant twelve, but I find no advantage from it; two plants to a light 3 feet apart, which, if an ordinary-sized frame 6 feet wide, will leave 18 inches between the plants and the frame.

After the plants are put in, water and shade until they are established, but if the frame is properly ventilated there is no need for shade afterwards. When they have grown about 4 inches high, take the point out of the leading shoot, thus causing the side shoots to appear; train these evenly over the bed, and grow them fast until they are 18 inches long. Then take the point out of each of these, which, in turn, push forth shoots, generally fruiting ones. These should be regulated and grown with the greatest care; when they show about two fruits each, stop them one joint beyond the last fruit, and on these coming into bloom, fertilise the female blossoms with the pollen from the male flowers, which should appear in abundance at this stage. During this process a dry atmosphere and more ventilation should be secured for the pollen to take effect.

After the fruit has begun to swell, and if the weather is favourable, a good watering will assist the plants, but at all times during their growth avoid too much water, keeping the soil moderately moist; but when water is applied, thoroughly soak the soil. I object to the common practice of syringing the foliage, as I consider the water lodges on the joints of the stem, causing them to canker and die off; besides, I find enough moisture rises from the soil to keep the foliage in perfect health if properly applied. At all favourable opportunities give them air early—say by seven in the morning, increasing it as the day advances, and shutting-up early—say by three o'clock; but in such hot weather like the present, a little may be left on all night.

After the crop of fruit is set, thin-out all superfluous growth as it appears; although enough must be left for the proper development of the plant and fruit, it is very easy to leave too much. As each fruit approaches its natural size, it may be be raised on small pots, not only to keep it clear of the water, but also to assist its ripening.

In growing this or any other sort of Melon, it is best to avoid planting new seed, or that saved from last year's fruit; such seed generally produces wood and foliage at the expense of the fruit, and will flag at the least exposure to the sun. I find that seed about four years old is in every way more desirable; the foliage is smaller and firmer in texture, consequently enduring the sun much better, the growth is more compact and fruitful. I therefore save a little seed of a favourite Melon every year, and date it properly, therefore avoiding any such mistake as above alluded to.—Thomas Record, *Hawkhurst*.

NOTES ON A FEW NATIVE HERBACEOUS PLANTS.

While so much has been done by horticulturists in introducing and cultivating exotics, it is curious to note how our native herbaceous plants have, with a few exceptions, been quietly passed by as if wholly incapable of improvement. I am not a believer in the absurd old adage which says that "familiarity breeds contempt," unless when the familiar object is really and truly contemptible; but it seems to have done so in this case, leaving many beautiful objects to be appreciated only by botanists, in whose eyes every green thing is interesting. Assuming such to be the case, there are some plants eminently worthy of cultivation, and just sufficiently rare to keep them out of the category of common plants. Foremost among these stands that strikingly handsome biennial

Echium vulgare.—This is thought by some to be the finest of all our native herbaceous plants. It grows to the height of 3 and sometimes 4 feet, and is of an upright formal character, and therefore well suited for single specimens in a border. It is composed of one central and sometimes as many as a dozen side compound spikes, all clothed nearly to the ground with a profusion of bright blue flowers, and as in some other Borageworts, an occasional pink one varies the general appearance. It is mostly found on waste sandy places by the sides of rivers, on chalky hills, and occasionally upon old crumbling wall

To cultivate it successfully, the border should be of deep light soil, free from trees, and otherwise unshaded. It is a biennial; the seeds should be sown in May or June, and the plants will flower in June and July in the following season. That it is inclined, even when not under cultivation, to break away from its normal state is very evident. Not to mention the white variety, which is by some considered to be a distinct species, there are numerous shades of blue, ranging from almost purple to the light azure tint of Myosotis. The variety of habit and size of flower as seen in different plants are also remarkable.

Myosotis palustris, the true Forget-me-not, with its blue and yellow flowers and its very pathetic but rather improbable legend, has always been a favourite flower; and although of a half-aquatic nature, it can be grown very well in any rather damp border.

Myosotis sylvatica is also now a well-known plant, being, along with some others not natives, largely employed for flower-garden purposes; but there is a dwarf or alpine form of it which is by no means so common. It is Myosotis alpestris, and is found only, in this country, near the summits of the highest mountains in the highlands of Perthshire and Aberdeenshire. I have seen plants of it under cultivation, and a gem it is in its way, having large dense heads of blue flowers. It is rather difficult to cultivate, and, I believe, requires the protection of a frame in winter.

The Vicias are a plebeian race, V. sativa being the common Vetch of cowhouse notoriety, yet among them we find some of our most beautiful climbing and trailing plants. V. sylvatica, though not rare, is far from being plentiful, and is mostly found in bushy "ghylls" up among the mountains. It grows to 4 or 6 feet in height, and bears a profusion of white flowers streaked with purple. Orobus sylvaticus, which is not nearly so beautiful, is sometimes mistaken for it. V. Cracca is very common, and very handsome with its long racemes of light purple flowers. For twisting lightly round the glass stem of a dinner-table flower-stand it is one of the most graceful things to be found, and I frequently use it for that purpose.

Mertensia maritima is another Borage wort, which I meant to notice after Echium. It is said not to be found on the English shores, but is frequently met with here, and all along the west Highland coast. It has fleshy, glaucous leaves, and curiously twisted rope-like roots, the loose racemes of small blue flowers being pretty rather than showy; but the whole appearance of the plant is exceedingly graceful. I have a few plants of it, which were struck from cuttings, as I found it impossible to extract the long bare roots from among the sand and stones where I found them. It is commonly called the Oyster plant, from the flavour of the leaves somewhat resembling that of oysters.

Calystegia Soldanella, the Seaside Convolvulus, is also well worthy of a place in the herbaceous border. It is an evergreen trailing plant, with very large rose-coloured flowers, which it produces abundantly during June and July. I have grown it for some years from seed saved from cultivated plants, but no varieties have been produced.

Parnassia palustris, the pretty cream-white Grass of Parnassus, though always described as a marsh plant, is nearly as often found on rather dryish upland pastures, from which it is easily transplanted, and grows tolerably well in an American peaty border. I read, not long ago, I think in "our Journal," as an instance of plant-growing under difficulties, of a lady in the city quarter of London, who grew this among some other plants in pots on the leads of the house! Doubtless, it was there as a *souvenir* of some breezy hillside, a wee bit of poetry carried home from the country, or, perhaps, it was set up as a standing protest against men's piling bricks on bricks as closely and thickly as if living flowers and fresh air were superfluities. —Ayrshire Gardener.

FRUIT PROSPECTS IN YORKSHIRE AND KENT.

The readers of "our Journal" must not conclude that because there is a small crop of fruit at Middlesbrough-on-Tees, therefore the fruit crop is a failure throughout Yorkshire. Living as I do in a cool part of Yorkshire, where the average rainfall is 36 inches, I have this year an abundant crop of fruit in my garden. The Peach trees, trained against a south brick wall without any glass protection or artificial heat, have set a most abundant crop. Hundreds of fruit had to be pulled off. The first thinning was made as soon as the fruit had cast off the blossom. The second and last thinning was done when it became possible to distinguish between the weak and the vigor-

ous fruit, and no more are left than what the trees ought to bring to perfection. My gardener considers it to be bad practice to leave the trees to thin themselves during the stoning process. Here such a thing as a fruit falling off, except when ripe, is not known.

I had the pleasure of seeing Mr. Rivers and his garden this spring, and was surprised to observe the almost total failure of his Peach crop. He attributed the loss of this fruit to the extreme moisture of the atmosphere while the trees were in flower. This wet made the pollen into paste. He was, however, quite unable to explain how it came to pass that the wet did not injure the pollen in my garden. I think we must look elsewhere if we would account satisfactorily for this failure. Strange as it may sound to many persons, I am convinced that last year was anything but a favourable year for the ripening of the Peach wood. The trees suffered from the extreme dryness of the soil throughout the summer, and were not improved by being stimulated into growth by the autumnal rains. The mischief then done developed itself in the spring. Here the long shoots shed almost all their flowers, which showed that the wood had not been sufficiently ripened in the autumn. But I never look for a crop from the long shoots; they are simply considered to be exhausters to draw the sap and prevent the spurs from being stimulated into growth by the autumn rains, and they performed this duty last year to admiration. My trees were covered with short well-ripened spurs. These this spring were first clusters of flowers, then dense knots of fruit. My Peach trees trained on this system have not failed for the last seven years to carry good crops.

The Cherry trees, as usual, are loaded with fruit. Pears set an enormous crop, and they provided my gardener with several days' work, first in thinning the trusses of bloom, and then in cutting off the superabundant fruit.

My Plum trees have to a great extent failed to perform their proper duties. There is but a sprinkling of fruit on six large trees, and I should have comforted myself under this failure by growling out something about pasty pollen and north-east winds, but it so happened that I had three Plum trees forked out of the ground last autumn, as I wished to satisfy myself as to the state of their roots. These three trees have each of them a good crop. So, then, it cannot be the winds, nor yet the rains, but the cultivation that is in fault. The fact is, our fruit trees are in too many instances left to take care of themselves. If they bear fruit, well; if not, it is the season—the wet or the dry, the winds, or the scarcity of bees, or the multiplicity of birds, or the flight of insects—anything, in fact, except the true cause. The Victoria Plum is as prolific as usual.

I have also an average crop of Apples. Those trees that have been grafted on the Paradise stock are doing better than those on the Crab. So you see I can with all thankfulness adopt your motto—"All's well."—C. M.

In an able article in *The Record* of July 7th on the food-producing prospects of the year, the writer observes that "Of fruit and vegetables there must be, under any circumstances, a lamentable paucity." In the case of fruit the assertion is unfortunately true enough, but as regards the supply of vegetables it is not so correct. Vegetables, so far as I have seen, are both abundant and of a fair average quality. The only crop to which any exception can be taken is that of some Potatoes; and even in this case, wherever a weakness of growth is perceptible, it is due more to the capricious weather of last season than to the inclemency of the past spring. But although the supply of vegetables is good, that of fruit is very much below par. Never did a year open with brighter prospects for fruit-growers than this, and never were hopes and trees together so ruthlessly blighted. After so hot a summer as that of 1868, tending to make the wood firm and well-ripened, with an abundance of blossom buds, it was reasonable to expect a fruitful year had the spring been favourable. But all these bright hopes have been dissipated, for surely never was known so disastrous a spring—from all parts come reports of scanty crops, foliage bruised, and in exposed situations torn to shreds; nor, so far as I can learn, are there any exceptions to this unfortunate state of affairs, but trees under almost all methods of training and culture have suffered alike. It is only on trees in very sheltered positions that fair crops are to be seen.

Standard Plum trees in most instances have a miserable crop of abortive bladder Plums, stoneless and deformed; while Cherry orchards, whose trees were "clouds of bloom," and whose fruit at one time appeared to be setting thickly, have shed their fruit to a ruinous extent, to the great loss of many fruit-speculators. A custom prevails in most parts of Kent, as soon as the blossom of orchard trees has fallen and the young fruit are visible, to sell the crop by auction. This year the prices obtained were generally very high, and consequently it will probably prove a disastrous season to the buyers. In one case, so abundant and so promising was the crop, that although the crop of last year was good, yet the highest bid of last year was almost doubled. Bush fruits do not appear to be materially affected. When looking over my neighbour Mr. White's fruit trees lately, I was amused to find him, while suffering from the loss of the greater part of his Apple crop, arranging for the planting of an additional half acre of Gooseberry bushes; and a very sensible proceeding I thought it, for Gooseberries are always marketable, and, taking the average price of the crop of a moderate-sized bush at 6*d*.—a safe figure, an acre containing 1200 bushes gives the very handsome sum of £30 annually.

I noticed a remarkably fine old Pear tree growing under the shelter of a steep cliff near Mr. White's house, on which the fruit clustered almost as thickly as Hops on a pole—an uncommon sight this summer, and I was assured that the same tree actually produced thirty-six bushels of fruit last year. Its name was unknown, but I fancy it is either the Swan's Egg or the small Autumn Bergamot.

Amongst Pears on walls Jargonelle, Louise Bonne, Napoléon, and that king of winter Pears, Winter Nelis, have good crops. Beurré Diel, too, has an excellent crop, which kind, although not a first-class dessert Pear, is yet a most useful hardy variety, and may almost invariably be depended upon for an annual supply. A tree growing here on an east wall has produced a full crop of fine fruit for five consecutive years, nor does its crop of the present season appear to be at all affected by the ungenial spring.

All the dwarf-growing fruits, such as Raspberries, Currants, and Gooseberries, are abundant. The last have been selling in the green state at from 5*s*. to 6*s*. per sieve of eight gallons to the dealers hereabouts. Concerning Strawberries, as I intend to offer some notes later in the season, I will only remark here that that most robust kind, Trollope's Victoria, has a heavy crop of fine fruit, quite equal to that of any other season. Peach, Nectarine, and Apricot trees have very healthy foliage, and are growing vigorously, but are, with very few exceptions, without fruit. Filberts and Cobnuts are also a short crop. Of Plums, a few trees on a south-west wall have a moderate sprinkling of fruit, but the Green Gage is a total failure.

But the most vexatious trial of all is that of those who have the care of unheated orchard houses. Their great failure will doubtless in many cases be a source of annoyance; yet if it result in the introduction of even a couple of pipes throughout the entire length of the orchard house, it will be fraught with much future good, not only to the fruit trees themselves, but by rendering the orchard house a most useful auxiliary for growing other crops, especially early in spring. So obvious are its uses in spring that it is almost unnecessary to recount them. If I did so, bedding stock, salading, Strawberries in pots, pot Roses, bulbs, and a host of other useful subjects would claim a notice, for no one will willingly trust any tender or half-hardy plant to our fickle springs, whose cold cutting blasts so often alternate with the tempting brightness of an April sunshine. Thatched hurdles, mat screens, and all such makeshifts are very well in their way; but, after all, it must be granted that a bright glass structure with a genial temperature, a free circulation of air, and where the wants of the plants can be attended to in all weathers, is altogether more convenient and more conducive to the health of the plants, not to mention the comfort of those who have the care of them.—Edward Luckhurst, *Egerton House Gardens, Kent.*

PELARGONIUM FLOWERS FALLING.

Attached to the back of my house in a northern suburb, with aspect nearly due south, is a small glass house, about 8 feet by 6, with board floor (being, in fact, built over the scullery). About five or six weeks ago I bought of a hawker half a dozen Pelargoniums and two Fuchsias in full bloom; these were placed at once in the house, and the next morning all the blooms had fallen. This I was not much surprised at, as the plants had evidently been grown in strong heat, and the sudden change of temperature I considered was sufficient to account for the misfortune. I have, however, just sustained a similar mishap under exactly opposite conditions, having pur-

chased half a dozen Scarlet Pelargoniums in full bloom, which were well-hardened plants, and appeared to have been bloomed out of doors; these were placed in the house, and the next morning all the blooms had fallen off. Fuchsias which have been in the same place since last year, have come fairly into bloom, although even in them there is a disposition for the buds to drop off before opening. Can you give any explanation of these results?—G. H. L.

[Your description is not full enough to enable us to point out the cause of the flowers dropping, especially in the second case. We can well understand that plants coming on in such a house would not suffer so much as plants bought and taken in, as they would be less liable to the noxious influence whatever it may be. With care in watering and plenty of ventilation, we can only think of the following:—First, in this hot weather, leave the house open as respects ventilation night and day. Secondly, is there nothing wrong on the part of the house? Is it lead, or zinc, and thoroughly dry? Thirdly, is the wooden floor free from a strong resinous exhalation? Fourth, is it so close as prevents all exhalations and vapour reaching it from the scullery? And lastly, is the house free from all influence from gaslights? It is just possible the last cause may be the especial one. We have under our notice at present three rooms in which plants did remarkably well in the windows, but lately they would not thrive, and the buds dwindled without opening. These rooms, though large, have had a little gas burned in them lately. On turning the plants outside they have grown and bloomed nicely; but the windows were shut before the gas was lighted. Nothing is so injurious to plant life as gas. We see any day the course of gas pipes through a grass field, and we can tell easily where there is an approach to a pin point in the deficiency of a joint of the pipes from the whitened state of the grass over the joint.]

WORK FOR THE WEEK.

KITCHEN GARDEN.

Ply the fork incessantly amongst growing crops of Broccoli, Cauliflowers, and Winter Greens; continue to manure and trench all ground as it becomes vacant, and plant it with late crops. Prepare trenches for late *Celery*, water the growing crops, and stir the soil among them. Prepare a patch of ground for the sowings of *Cabbages* to stand the winter: the soil should not be too rich, as it encourages a luxuriant growth, which is apt to make the plants tender. Plant out finally the strongest *Endive* from the early sowings, and sow more for late crops. The Small Green Curled is the best. Pull up the crops of winter *Onions*, place them in rows with the roots towards the sun, and frequently turn them until the stalks are withered; they will then be fit for storing. They should be carefully handled. Let them be very dry when stored, and spread out thinly, not laid in heaps. *Garlic* and *Shallots* should also be taken up and dried for storing. The lifting of *Potatoes* must be proceeded with as fast as they become ripe. The late-sown *Peas* should have attention paid to watering and staking. Sow, also, more Lettuce, and keep up a good succession of *Radishes* and *Salads*. Dredge the young *Turnips* and other seedling plants while damp, early in the morning with dry charcoal dust or wood ashes; also continue to keep a watchful eye on the caterpillars which infest the Cabbage tribe.

FRUIT GARDEN.

It may still be advisable to go over such trees as are overluxuriant, and stop about half the shoots, beginning, of course, with the strongest; for a general stopping at this time would probably be of little farther service than to induce the production of a mass of useless spray; whereas stopping the stronger shoots, or those which incline to grossness, will divert the sap into the weaker ones, which will be strengthened, while the buds on the shoots which have been stopped will become full and plump without starting into growth. The only effectual method, however, of curing a gross habit of growth when this is the case in ordinary seasons, is root-pruning, or keeping the roots within proper limits by means of shallow, well-drained borders. Should it be found that the shoots after stopping, incline to start into growth, it will be advisable as soon as the fruit is gathered, to open a trench at a moderate distance from the stem of the tree, cutting the stronger roots. This will be of the greatest service in checking growth, and will probably do more towards securing ripe wood than anything else that could be adopted. Early Pears should be gathered before they are quite ripe, by which their juiciness will be increased. Let Strawberry plantations intended to stand for next season be trimmed as soon as convenient, cutting off and clearing away the runners so as to afford the leaves plenty of room.

FLOWER GARDEN.

Decayed blooms should be removed from Roses, for if allowed to hang they have a very untidy appearance, and tend to encourage mildew. Roses, if in masses or beds, should be arranged so that their colours may be as much contrasted as possible; where this has not been hitherto attended to, the present arrangement should be carefully examined while the plants are in flower, and any alterations noted that may be considered necessary to render the effect more satisfactory next season. Proceed with the propagation of favourite sorts, either by means of budding or cuttings. Many prefer having Hybrid Perpetual, Tea, China, and Bourbon Roses on their own roots. Short-jointed cuttings taken off now will root freely if properly made and attended to under a hand-glass, provided the situation is somewhat warm and shaded. The readiest way of propagating them, however, is by means of cuttings taken off plants grown under glass for flowering in spring. If judiciously selected they will root almost as freely as Verbenas. In some neighbourhoods black fly is becoming troublesome on Dahlias and Asters. When such is the case tobacco water and soapsuds may be used with advantage. The strength of the mixture should be tested by dipping into it some of the shoots worst affected, and using it sufficiently strong to kill the insects, but not so much so as to injure the leaves. It should be applied in the evening when there is a prospect of a dry night, using a fine-rosed syringe or watering-pot, and giving enough to moisten the whole of the leaves. Go over beds of Verbenas frequently, and remedy any defects that may be perceptible without loss of time. When the stock is growing vigorously, pegging and training will involve considerable attention, and it will be necessary to inspect the beds frequently, removing decayed flowers and cutting back such of the shoots as may incline to encroach upon the edging of the beds. Keep herbaceous plants neatly tied-up, and cut off the flower stems of any becoming unsightly. Take advantage of any spare time to put in cuttings of choice plants. Keep gravel walks smooth and neat by weeding, sweeping, and rolling.

GREENHOUSE AND CONSERVATORY.

Now, when most kinds of hardwooded greenhouse plants are out of doors, painting and other repairs required by the houses in which they are grown should be done; for paint, to stand well, it should only be put on when the woodwork is thoroughly dry. Therefore, be sure that this is so before commencing. As already stated, it is now time to provide plants adapted for blooming late in autumn, and early in winter. Camellias, if forced into wood will be tolerably forward. They should be kept out of doors in a good place on coal ashes to prevent worms from deranging the drainage. Chrysanthemums should now or very soon receive their last shift, using chiefly, if possible, good fibrous loam with plenty of charcoal. This is the best way to keep them stiff in habit, and to preserve their lower leaves. Any necessary amount of strength may be imparted to them when the flower-buds are formed, by good liquid manure. Successions of Bragmansias, Clerodendrons, Euphorbias, Poinsettias, &c., should receive a last shift, in order that they may produce a rich display in the conservatory. Climbers on ornamental trellises should be occasionally cut back with the view of having a succession late in the season, when flowers become scarce. A batch of such plants as Thunbergias, Ipomœas, Jasmines, Stephanotis, and Passifloras, should be trained up ornamental trellises without delay. Clematis bicolor, and C. azurea grandiflora, force well early in spring, provided they are rested behind a shady wall for a month or two about this season. The latter plants, although perfectly hardy, are well adapted for conservatory trellises. The forward Achimenes will have produced abundance of suckers; these, taken off and encouraged in a propagating frame, will produce a very late display.

STOVE.

Those who desire success in this as well as most other departments of gardening where artificial heat is required, must look well to the stoke-hole department. The proper management of the fires is at least one-half the affair, especially as connected with smoke flues and other incomplete apparatus, which still exist in a majority of country gardens. The eastern Orchids will certainly not do without fire heat, even at this period. It is, therefore, considered the best policy to light the Orchid or stove fire about two o'clock, to burn a small lively

fire for three hours, and suffer the fire to die away by five o'clock, shutting up entirely for the night by six o'clock. At this hour the piping will possess warmth enough to insure a temperature of 65° or 70° throughout the night. This heat, with plenty of moisture sprinkled in the house, and slight syringings, will secure an atmosphere of a most genial character. —W. Keane.

DOINGS OF THE LAST WEEK.

The chief work of the week, besides the routine lately alluded to, has reference chiefly to surface-stirring the soil, mulching, and watering. The surface-stirring has been given where possible, to growing crops in all departments. It is astonishing how this alone helps plants, even though newly turned out, to resist the almost tropical sun which has come upon us at last. Excessive evaporation and the descent of heat is arrested by the loose surface. Even our flower beds—the few open spaces still to be seen—showed signs of cracking, especially round the sides of raised beds, to prevent which nothing is so good as keeping the surface open and loose with the hoe. Hoeing carefully among small edging plants often does more good than sprinkling them with water. Some of our best gardeners are using the water pail with great moderation out of doors. In deep good soil established plants can well hold their own, especially when the surface is kept loose.

Mulching is a great relief where a heated soil is of less importance than a moist one. Peas and Beans at midday seemed to show the effects of the sun and drooped their points a little; in such a case we could not expect the younger succession flowers to set and swell well. Even when watering could be given, it was followed either by hoeing or mulching; but generally with the latter, as the former is usually employed before watering, even if nothing better than litter or grass can be obtained. We have even mowed some outlying corners to have the long grass for this purpose, and all the short machinings from lawn, &c., have been taken to the kitchen garden instead of the rubbish or rotting heap, and placed at once among Peas, Cauliflower, &c. Even this requires a little care to pack about the stems and over the ground, but not over the plants. We find that a careless workman had allowed some to drop in the centres of strong Cauliflower plants, and had it not been seen and removed it would have stained and disfigured the coming fine heads. Thickish mulchings may safely be given to all plants as the heat in the soil is now quite sufficient for them. There is just this danger from a thickish mulching of grass cattings, &c., that after a shower or two, it becomes so close as almost to exclude air; and on a slope, the rains would run away to the lowest parts. This is easily avoided by breaking the surface of the mulching with a hoe or fork, when air and rain will have a free entrance, whilst the soil is kept moister and cooler than it would otherwise be.

In the flower garden we have mulched, as already stated, Calceolarias with rather fine hotbed manure, of dung and leaves fairly decomposed. We have done the same lately to Lobelias, Verbenas, Pentstemons, Roses, &c., but we have not yet done anything in that way to Scarlet Pelargoniums, as for them the soil is not too warm, or yet too dry where the plants are pretty well established. If this hot weather should not continue long, we would not mulch them at all, unless from extra free-blooming they should need a little extra help. We never knew them grow less after they were turned out, than they did this season; which was owing not so much to the cold mornings as to the coldness of the soil. The last ten days they have been picking up, growing vigorously, and opening their blooms fairly, but we do not like just yet to cool the soil by watering or mulching; in fact, when well established, Scarlet Geraniums planted out in deep-stirred soil need but little watering, and their own leaves act as a fair mulching, so far as keeping the sun heat from the ground. Extra free-blooming, however, is apt to exhaust the plants before the autumn is over, and to prevent that, and also avoid watering, except what the heavens give us, nothing is better than a little mulching of rotten dung. Remember that this surface-mulching and manuring has quite a different effect from digging it deep in the soil where the roots would at once take hold. The latter plan would encourage vigorous growth, even at the expense of thinner blooming; the former would tell chiefly in supporting medium-sized foliage and free-blooming.

Watering.—This is as usual becoming a serious affair, but we hope we shall not experience a repetition of the evils of last summer. A thunder-storm with a heavy rain, which we hope is not far off, would give us a good supply and replenish our failing resources. Even here it would be easy, with more tanks and reservoirs, to store just four times the quantity of rain water we do. Celery, Peas, and Beans have had what we could safely give them, and fine rows of Lettuces have been mulched to make a little liquid go a great way.

In the flower garden, the outside rows of raised beds have had a little, and the watering has been confined chiefly to them. We mentioned raising a lot of beds at the outsides with stakes about a foot above the lawn surface, and planting Sedums, Moss Saxifrage, and wild small-leaved Ivy to cover the stakes. Owing to the heat, some of the sides of the beds, as those planted with the Saxifrage, will scarcely be covered this season. Sedums have done their work very well. The raising of the outside of the beds has given us two advantages the machine goes readily round without touching any straggling shoot or plant; and the raising and thick planting at the outside prevents the birds scratching the soil all over the lawn near the beds. Though the staking is done neatly, we do not consider the stakes an ornament in themselves, and where we think they would not soon be covered, we have planted some temporary plants at their base, as Variegated Alyssum, lilac Asperula, &c., just to hide them neatly for the season. One other advantage of thus raising the outside of the beds and thus draping them with green is, that you have a green outside all the winter, and a good preparation made for spring and winter gardening, if that is deemed necessary. We have long had raised beds with the outsides densely covered with Ivy, and these gave us no extra trouble whatever in the way of watering, as the Ivy kept the outsides cool. *The Ivy, be it kept in mind, not planted in the bed, but at the base of the stakes outside.* On such beds established for many years, we had this season to place some new stakes to keep the Ivy in its place. In many cases it is now strong enough to keep itself in shape without stakes. In the case of the beds freshly done, when the stakes are covered with the Moss Saxifrage, &c., the outside edging close to the stakes inside the bed, will need no more watering than any other part of the bed. But where the stakes are not well covered, the ground next them inside will become drier, and we have run a little water round them outside to make up for the greater exposure, and stirred the surface shortly afterwards.

The Calceolarias were never more dense, not an inch of ground is to be seen for their heads of bloom, but to keep successions on we shall have to water in the beginning of the week, and our hitherto refraining has been owing to the mulching. Some of our finest beds are defective, from the deer having made havoc of edgings of purple and blue Heartsease. These did us good service, not only in the spring, but through the summer of last year, being, we believe the same colours and the kinds used at Cliveden, and which, with the moist, cool treatment given to Calceolarias generally, do well when fresh planted, for the whole summer. We have had them several times cut right into the ground, and other things almost untouched. Nothing was touched but these Heartsease, and some beds of Verbenas that had not a flower left on them. To make the Calceolarias right, we must have a blue or purple edging, and we have a nice lot of good plants in boxes, of Lobelia ramosa, which if well watered, will nestle up to and fringe the Calceolarias. This is a Lobelia not estimated as it deserves to be, with blue flowers large for the size of the plant. Mr. Hills, at The Poles, grows it in pots very much for spring and early summer decoration. We saw numbers in 4-inch pots a mass of dense beautiful blue.

As already mentioned, we will give little water as yet to the Geraniums out of doors, but will rather let them feel the heat, as the soil is not yet too warm for them. If the weather continues so hot, we will surface-stir again, water, and then mulch.

Such weather as this furnishes the best of all details about watering plants in pots. "How often should I water?" is the perplexing question often put to us. "Only just so often as the plant needs it," is the only right answer to give, "and then give enough to satisfy its wants." A plant must be treated as we would treat ourselves. When a man is thirsty a glass of pure coolish water is the greatest luxury; if not thirsty, forcing him to drink it would be a punishment. A plant may do without water for more than a week in wintor; once or twice a-week may be enough in cloudy weather in spring; but in such weather as this, plants in pots may need refreshing twice a-day, and that not a whit too much. Large plants in pots, if mulched, will need less watering, as that will prevent evaporation. All plants under glass should not only be watered,

but evaporation from them lessened by syringing the stages, and damping walls and floors with the syringe.

There are one or two things we would just notice resulting from this hot weather. In a recent visit to Luton Hoo, among much to gratify us, we were sorry to find that the largest bunch of Musa Cavendishii fruit we had ever seen, had been cut and used; but we were particularly pleased with two things, the house of Melons previously noticed had been used and fresh planted, and there were abundance of Melons in pits, heated and unheated. Perhaps the most gratifying was a fine lot of fruit in a low span-roofed pit, used generally in winter for Violets, and having no artificial heat besides a little dung below the soil. As the fruit was chiefly collected at the outsides, the mode of treatment and training had been much the same as we had frequently recommended. The next thing was, that though the excessive heat threatened to lessen the time of the Strawberry season, in ordinary circumstances, Mr. Cadger had been fortunate enough to turn out a lot of his huge forced plants of Keens' Seedling early in spring, we think in the end of February, and these in rather a cool, sheltered border, have shown and set in armfuls, so that with a little watering, the Strawberry season will be greatly prolonged.

One thing used to trouble us in visiting some places, and that was the bad condition of the walks, the sides being covered with young weeds, Daisies, &c., the result of leaving the grass next them too long, and thus permitting the walks to be seeded. All walks to be preserved neatly should have the grass kept short for a width of a scythe swathe. It will do wonders towards keeping walks clean. It will also aid much in dispensing with hoeing, raking, turning, or salting, the latter process though killing the weeds always has a tendency for making fine walks finer and softer. With rough walks salting will help to make them finer, and, therefore, more pleasant to the feet.

We may now mention a rather heavy piece of work with our *pleasure ground walks*. They are in fair order—hard and firm, but a few small weeds can be seen if you look well for them. We want them to be bright, fresh, and clean for the summer with but little trouble. We have, therefore, procured some loads of rather bright pit sand; we are sprinkling the walks all over with salt, and we shall then follow with a sprinkling of sand, which conceals the salt. This sprinkling will be a little loose before we have a good shower; but afterwards a brisk sweeping with a broom, and a run-over with a roller, makes all join together, and the walk looks neat and clean for the season. We could clear off the weeds from our firm walks by salting alone; but then if we did so, we know that until every particle of the salt was washed out, the surface of these walks would be soft and unpleasant in wet weather. By adding the fresh surfacing, or rather sprinkling of riddled sand, the salt acts upwards a little as well as downwards, but not sufficiently upwards to prevent the surface being clean and firm to the foot in moist weather. The evil of salting smooth walks without some such precaution, is that they become too smooth, and then soft in wet weather.

One word more respecting lawns. We have run the machine lightly over part of ours, but in other parts, where only a few Daisies, Bents, and Plantains appeared, we have preferred sweeping them off with the Daisy knife. Close and frequent cutting now in such sun, will greatly encourage scorching and burning; and we should rather avoid than encourage that result. The finest flower beds are a poor sight with a scorched and burned-up lawn around them.—R. F.

COVENT GARDEN MARKET.—July 21.

We have had some difficulty in maintaining last week's prices, as the supply has been much in excess of the demand. Forced fruit are very plentiful, and foreign importations heavy, comprising Pines, Peaches, Nectarines, Apricots, Cherries, and Jargonelle Pears. Potatoes good, and a ready sale at former quotations.

FRUIT.

	s.	d.	s.	d
Apples ..... ½ sieve	2	0	to 0	0
Apricots ..... doz.	2	0	3	0

TO CORRESPONDENTS.

N.B.—Many questions must remain unanswered until next week.

Books (*J. C. Paterson*).—We purpose continuing the work until all our native plants have been portrayed and described. We are unable to publish more than four monthly: if we could have done so the work would by this time have been complete. (*W. G. C.*—Keane's "In-door Gardening" may suit you. It can be had from our office if you enclose twenty stamps, with your address. (*J. Booth*.—"In-door Gardening" as above; and "The Garden Manual" the latter free by post for twenty postage stamps.

Dark Climbing Roses (*J. C. Lower*).—"I have no doubt that the Rose you describe is the old Tuscany. It has a single row of petals with golden stamens, and is very nearly black or blackish maroon. It flowers only once in the season. The blooms are most abundant, and very beautiful. There was a noble tree of it at Rushton. Doubtless, our very dark Roses are derived from it. Buy these, and they will please you—Prince Camille de Rohan, Empereur de Maroc and Souvenir de Dr. Jamain. They are Hybrid Perpetuals. They are all very dark, abundant bloomers, and very beautiful. Put them against your south or south-east wall, and when winter sets in with severity, place matting over them till danger is over.—W. F. Radclyffe."

Sowing Verbena Seed (*Idem*).—To have good strong plants for blooming early next year, you may sow the seed now. Well drain a seed-pan, and fill it to three-fourths its depth with two-thirds turfy light loam and one-third leaf mould, then to the rim or nearly so, with the same soil sifted, adding one-sixth part of silver sand. Level the surface by pressing it with the bottom of a small flower-pot, and scatter the seeds evenly, just covering them with fine soil. Give a gentle watering, place the pan in a cold frame or under a hand-glass, and shade from bright sun. Keep moist and close until the young plants appear, then admit a little air, increasing the amount with the advance in growth of the plants. When these are large enough to handle, they may be pricked-off in pans at about 1½ to 2 inches apart, and kept rather close and shaded for a few days until established. Harden them well off, protecting them only from frost and heavy rains, and giving all the air possible; before severe weather sets in remove them to a shelf or light airy position in the greenhouse. In February or March the plants may be shortened to 2 or 3 inches, and cuttings made of the parts removed, which will strike freely in a mild hotbed. When the plants have made fresh shoots an inch long, they ought to be potted off singly, or placed 3 inches apart in pans, and shaded until established; then harden them off and remove them to a cold frame, protecting them from frost by a covering of mats. You may obtain one or more lots of cuttings from them, and these with the old plants will be fit for planting out in May. Seedling Verbenas are of little use for bedding except in mixed beds. The seed may be sown in March, and the plants from that sowing will be large enough for planting out at the end of May.

Gladiolus Blooming (*An Amateur*).—The only way of securing long spikes is to grow the bulbs in rich soil, give top-dressings of rich compost, and supply well with water, syringing overhead every evening in hot weather so as to keep down red spider, and promote vigorous growth. A long loose spike is undesirable.

Dahlias Flowering (*Idem*).—In the first place the plants should have a single shoot only, and it should be secured to a stout stake driven firmly into the ground. The side shoots as they appear should be regulated, thinning out the weak, and preserving enough of the strong to form a sufficiently compact but open head. The side shoots must be secured to the principal stake with long shreds of matting, so as to permit of their assuming the branching habit peculiar to them. If the tying is not sufficient to secure them against winds, it will be necessary to place three or four stakes besides the centre one, and though the stems are tolerably close to it at the bottom, the tops must incline outwards sufficiently to allow of the side shoots being kept secure from heavy rains or wind. The pruning should be confined to thinning out the weak shoots, and preserving a head of healthy shoots. The first blooms, as a rule, are not very good: you may cut them away, and also any that are not of good form in the bud. The best liquid manure is a peck of sheep's droppings and a peck of soot to thirty gallons of water, well stirred up and dissolved. It may be applied twice a-week, stirring well up each time. Guano at the rate of 2 ozs. to the gallon also forms a good liquid manure.

Liquid Manure (*A. Lockyer*).—To Cabbages and similar crops you may safely use it once a-week, at the rate of 1 oz. to the gallon of water. For other plants you may use double the quantity that you would do of guano. The drainings of rabbit hutches make an excellent liquid manure diluted with water or absorbed by sawdust. The amount of water added would depend on the kind of plant to which the manure is to be applied, and the amount of solid matter along with the urine. The letters used indicate commended, highly commended, very highly commended.

Scaring Birds (*Somerset*).—Suspending pieces of glass from sticks to

frighten birds by their jingling has been practised in cottage gardens as long as we can recollect.

Vicomtesse Héricart de Thury Strawberry (*Constant Reader; C. Wade*).—We cannot recommend dealers. As we knew of more than one nurseryman who has the variety, to single out one would be unfair to the others. Those who have the variety should consult their interests by advertising the fact.

Strawberry Plants (*J. G. Pearson*).—We cannot recommend tradesmen. Any of the principal nurserymen who advertise in our Journal could supply you.

Blind Strawberry Blossoms (*K. K.*).—We are at a loss to know whether you mean blossoms in which the organs of fructification are entirely wanting, or those in which they have been destroyed or proved inefficient. The first is of comparatively rare occurrence in this country. It is sometimes caused through weakness, and sometimes by defective constitution; such plants ought to be discarded. The other is owing to climatal or atmospheric influences, by which the parts have been injured or prevented from performing their functions. The Vicomtesse Héricart de Thury Strawberry will in our opinion suit your soil and locality well. We agree with our correspondent.

Glass over a Vine (*J. R. P.*).—We approve of your proposed plan, but we would recommend the rafter sashbars being from 12 to 15 inches apart, and the rods should be suspended from the rafters, so as to be 12 to 15 inches from the glass.

Grapes Decaying (*J. S. Lightbounds*).—They are severely affected with the "spot," as gardeners name the ulceration. The roots, probably, do not supply sufficient sap. Plunge the pots in the soil down to their rims, and water with tepid weak liquid manure.

Vine Border—Strawberry Plants (*T. W. R. C.*).—Mulch the Vine border at once—you should give it a good soaking with water before putting on the mulch. Peg the runners into small pots. When well rooted you may separate them from the parent plants and put them into a cold frame as you propose.

Vine Leaves Insect-Infested and Diseased (*J. H. C.*).—The small leaf is rusted—an evil mostly produced by too much heat, followed by a sudden reduction of temperature; and the rust has been followed by mildew, which you may destroy by dusting them with flowers of sulphur. The large leaf is mildewed, and all in a similar state should be dusted with flowers of sulphur. On the large leaf there are besides traces of thrips, which you must destroy by fumigating with tobacco when the foliage is dry, shutting the house up closely, and on a calm evening densely filling it with smoke. The fumigation should be repeated the next night but one, and during the day keep the atmosphere moist, and as close as the state of the weather will permit. In the following day give a thorough syringing, and, whilst the leaves are wet, dust them with flowers of sulphur; the following evening, heat the pipes or flues to 168°, shut up the house, and coat them with sulphur brought to the consistency of thin paint by a solution of soft soap at the rate of 2 ozs. to the gallon of water, using a brush, and going over them twice or thrice so as to thoroughly fill the atmosphere with sulphur fumes. This will destroy the red spider, or reduce it considerably, and you may by heating the pipes cause the sulphurous fumes to be given off, which will keep the red spider under. There are evidences of thrips, red spider, and mildew on the leaves sent; it is a bad case, but not so bad as one we saw lately where there were thrips, red spider, mildew, and mealy bug, not a bunch in more than one large house, being fit for table. If the thrips reappear repeat the fumigation.

Cucumbers for Early and Main Crop (*Idem*). — You do not say whether you require them for house or framework. If for house, Telegraph is the best winter sort that we have grown, and Dickson's All the Year Round is a good companion. For frames the first named or either of them, and Newton Hero, or if you want one for exhibition Dale's Conqueror.

Arum Repotting (*Young*).—It is now a good time to divide and repot, keeping rather moist and shaded from bright sun for a few days. A compost of two-thirds turfy loam, and one-third leaf mould will grow them well, adding sand liberally. The Clover is merely a dark-leaved Suckling Clover (Trifolium minus) one of the best sorts for lawns, as it withstands drought well.

Tank Heating (*C. R. C. Vigurs*).—Why not continue the tank in the cast house the same as in the west house? You would require to do so—that is, have more heat, if you wished early Cucumbers and Melons; but merely for summer Cucumbers and winter vegetables the heat will be quite sufficient without the help of a flue, as you have in the western house. You will not gain so much by continuous heat from a tank over hot water as you may imagine; but if slate is cheap that is a consideration, and if so, you might have the sides of slate as well as top and bottom. The size of the tank in two divisions, 3 feet wide, will be ample; and so would 6 inches in depth, or even less, as the deeper the tank the colder will the water be at the bottom, however warm it may be at the top. In either house, to prevent damp from the tank, it should be fixed secure on the top with red or white lead, which is better than cement. Three feet would be too far from the glass for Lettuces, &c., in winter. 18 inches would be better, but the first will do if you give plenty of ventilation. We have had fine Lettuces farther from the glass. The same remark applies to Cucumbers and Melons, but in their case, after planting them out, you could train them to a stem and then on a trellis 16 inches from the glass. A few bits of wire, or even a few pieces of wood and string, would make a good trellis. We depend most on the flue for heating the greenhouse. The tank covered with earth banks, will be of little benefit in heating the house, as only one side next the path will be exposed, and thus give out heat to the house. This will answer well enough with you in Cornwall, where you have no frost to speak of; but if you should want more heat in the atmosphere of the house, you could easily have it by placing 6 inches of open rubble over your tank and then the earth, or rather we should use gravel and sand for setting the pots on. We would have pipes, say 2 or 3 inches in diameter, rising from near the slate, through earth or sand, both ends open, the upper one plugged, and by moving this plug we could let heat out as we wished, and either a damp or a dry heat at will. We would like this house the best for early Cucumbers and even Melons, and with the flue in front there would be an abundance of heat. You are quite right as to the advantage of such an earth or sand platform over wooden shelves, for they retain moisture, and make the plants more independent of the water-pail. Many plants, as Fuchsias and Scarlet Pelargoniums, do exceedingly well on such earth platforms; but the finer kinds of fancy and florists' Pelargoniums do better on wooden shelves than on anything else, except slate. When standing on a damp bottom they are apt to be troubled with spot and discoloured leaves. What we have stated as to the open rubble over the tank, is of importance when you do not merely set plants on the earth or other covering, but grow them in it, as with a close cover to the tank, as there ought to be, the soil becomes too dry, and with the rubble and pipes referred to it is always easy to have moisture beneath without directly communicating with the tank. It is a fact that many are slow to believe, that a close-covered slate tank gives out as dry a heat as iron pipes.

Pine Scale (*Robin Rove*).—You are quite right. When plants are very much infested the best plan is to burn the whole. The scale is very difficult to eradicate when the roots are infested. If the leaves only are infested continued applications of warm soap water will clear them, especially if you daub everyone that appears with gum arabic or glue water, just strong enough to stick on them. All the recipes are good when persevered in, and everybody likes their own the best. If the scale (the shell of the mother, beneath which the almost imperceptible young ones are brought to maturity), is on the roots, they must be disrooted and washed. We like simple methods, and have found nothing better than soft soap water, say 1 lb. of soap to sixteen gallons, well dissolved and cleared a little, and the plants turned into it in a tub at a temperature of 110°, kept there for half an hour, and then roots, stems, and leaves washed. When the roots were but little affected, we have found no better and simpler remedy than rank horse dung. We have let the steam in from the linings; but we prefer in such a pit as yours to set the plants closer, and put half a dozen barrowfuls of fresh horse droppings in a place, and provided no Pine plants are very near, let the fumes escape all over the house, shutting up early, making plenty of steam from watering floors, walls, pipes, and turning the dung over when you shut up. If you can scarcely see your finger before you, all the better. If the heat rises in such a damp ammoniacal vapour to from 95° to 100°, no harm will be done. Hardly an insect will stand such treatment, and no growing plant that we know of will stand it except the Pine Apple. With such doses repeated, and dislodging, or rather covering every one that appeared with size water, we have cleaned very dirty plants, but with labour and trouble. The advantage of the dung or the ammoniacal fumes is, that it penetrates all the crevices of the house, and thus saves washing. When using such fumes and steam the houses should be shaded during the day instead of giving much or any air. We would not scruple in such a vapour bath to let the houses in the shade rise to from 95° to 100°. You might try on a small scale what such fumes would do by pouring some muriate of ammonia or quicklime in a confined place, but we like the fresh stable dung.

Custard Apple (*G. H.*).—The Vegetable Marrow you have sent must have come from a seed accidentally mixed in the soil. It could not have been produced from a seed of the Anona, or Custard Apple.

Yellow Bedding Flowers (*C. H.*).—Besides Calceolarias, the Tagetes tenuifolia and dwarf yellow Marigolds are good for bedding, but the best substitutes for the Calceolaria are the Yellow and Tricolor Pelargoniums. If you give yourself a little trouble in disleafing, yellow Nasturtiums of the dwarf Tom Thumb kinds make brilliant beds. To secure a fine display, all extra foliage must be picked off, and all faded blooms and seeding prevented. If you can commend water and rich top-dressing, yellow Pansies, as the Cliveden Yellow, keep fine all the season, but they will become poor without that attention.

Gas-heating (*T. L.*).—Before you do anything with heating with gas, read what was said on the subject, and notice the figures given in illustration, in our No. 341. Gas is chiefly useful for small houses, and in every case the products from the burnt gas must have a tube for their escape into the open air. Argand burners decompose the gas most thoroughly.

Orchids for a Greenhouse (*F. G.*).—Orchids cannot well be grown under bell-glasses, as the atmosphere is too close; but these, especially if made with moveable tops, would be of service when the plants are making new growths. The glasses would only be required from the time of the plants commencing to grow until attaining their full development, when they should be removed. Whilst over the plants, they should be taken off twice a-day and wiped dry, and take care to admit air, so as to have the foliage dry at least once in a day. Orchids cannot endure a still, stifling atmosphere, but like air in constant but gentle motion, and the only advantage of bell-glasses would be, that you could give the Orchid the moisture necessary to a free growth without making the whole atmosphere too moist for the other occupants of the greenhouse. The following would succeed in a greenhouse with or without bell-glasses:—*Acropera Loddigesi, Angulea Clowesi, A. uniflora superba, Barkeria elegans, B. Skinneri, Brassia verrucosa, *Calanthe vestita lutea, *Cœlogyne cristata, C. maculata, C. lagenaria, C. præcox, Cymbidium aloifolium, Cypripedium insigne, *C. venustum, Epidendrum vitellinum, *Leptotes bicolor, *Lycaste cruenta, *L. Skinneri vars., *Maxillaria Harrisoniæ, Odontoglossum *Alexandræ, bicteniense, citrosmum, cristatum, Dawsonianum, gloriosum, *grande, Insleayi, *maculatum, nebulosum, *O. Pescatorei, O. pulchellum, Oncidium cornigerum, O. divaricatum, *O. sphacelatum. Disa grandiflora would not thrive under a bell-glass, as it requires as much air as a mountain Daisy. Those marked with an asterisk would be most likely to succeed under the hand-glass treatment.

Wistaria Shoots Dying (*S. A. C.*).—We are unable to account for the shoots dying, but think it mainly due to a want of proper moisture, as we find a few good waterings in spring and early summer prevent the dying away of the young shoots to a great extent. Holes should be made with a crowbar a foot deep or more, and the holes repeatedly filled with water; when the soil has been well moistened, fill up the holes with fine soil.

Destroying Beetles (*Lucas*).—They may be poisoned by placing phosphorus paste on thin slices of bread, or on strips of paper, near their haunts; but you must be careful to keep it from the reach of domestic animals and birds. A hedgehog is an effective but despised natural destroyer of such pests. They do no harm, and destroy great numbers of garden vermin.

Plants and Climbers for Conservatory (*Miss W.*).—For the centre bed we should advise Camellias, interspersed among the Aloes and Dracænas, to take away their stiffness. If we understand your question rightly, you wish to know what plants and climbers would be suitable for

covering the roof and walls. For the walls, Cestrum aurantiacum and Luculia gratissima; for the pillars, Mimosa prostrata, Plumbago capensis, Habrothamnus elegans, Abelia, and magnificus; for the roof, Tacsonia Van-Volxemii, Sollya heterophylla, Passiflora Newmanni, Lapageria rosea, Mandevilla suaveolens, Bignonia jasminoides splendida.

Insects (*W. E. B.*).—They are the larvæ of one of the Lady-birds (Coccinella), and destroy the aphides on plants as effectually as do their parents. Of course they have nothing to do with the Potato tops dying.

Names of Plants (*Nora*).—Briza maxima. Commonly grown in gardens. Propagate by seeds. (*Beatrice*).—Cardamine hirsuta. (*M. E. Crosby*).—Cyrtomium falcatum; 3, Spiræa aruncifolia. (*T. Brooks*).—Saxifraga herbacea. (*W. C. H.*).—3, Spiræa Douglasii.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending July 20th.

Date.	Barometer.		Thermometer. Air.		Thermometer. Earth.		Wind.	Rain in inches.	General Remarks.
	Max.	Min.	Max.	Min.	1 ft. dp.	2 ft. dp.

POULTRY, BEE, AND PIGEON CHRONICLE.

MUTILATION OF FOWLS.

I am exceedingly sorry to see by your paper, one of Mr. Entwisle's Bantams shown at Ipswich returned home minus its sickle feathers. Permit me to say, I also received a note from Mr. E. informing me of the injury, and also that Mr. Adams asked him to telegraph the price of the birds; so, perhaps, you will allow me in fairness to Mr. Adams to state that he was not in the Exhibition at the time of packing, and further, those birds were packed by gentlemen of unimpeachable standing. I can answer for their feathers being intact when they were packed as when they arrived. I regret not being able to throw any light on the affair, as no person would be more ready to expose an injury to poultry at exhibitions than your correspondent.—W. B. Jeffries, *Hon. Sec. of the Ipswich Poultry Society.*

BISHOP AUCKLAND POULTRY SHOW.

The first Show of Poultry, Pigeons, Rabbits, and Cage Birds, was held here on the 17th inst., under most favorable circumstances. The birds were provided with an excellent tent, Turner's pens were used, and altogether the management was of the highest character. Considering this is the first attempt, it promises well for future exhibitions.

In the class where a special prize was offered for "Any variety" of poultry, the pen of cock and two hens to be placed at the disposal of the Committee, at 21*s.* the pen, *Brahmas* of good quality were in the fore, but the class as a whole was very poor. *Game*, Black and other Reds, were not of high merit, but the first-prize pen of Duckwings were excellent. *Spanish* were also good and in prime condition; but for quality the *Dorkings*, as a class, stood highest, every pen being noticed. *Brahma Pootras* were moderate, and in *Cochins* there were some capital birds, notably so in the first-prize pen. In *Polands* and the *Hamburghs* generally, it would be almost impossible to find more superior birds than the winners; and the first-prize *Houdans* in the Variety class were faultless. *Game Bantams* were large in entries, though only moderate in quality. Bantams, any other kind, if we except the Pekins in the first-prize pen, were not worthy of notice.

Ducks were not good, except the first-prize wild; but the *Goslings* and *Geese* were both very large and good.

Pigeons were not a good collection, though there was here and there a moderate pair.

Rabbits were of the mongrel variety.

Most of the *Cage Birds* were low in condition and out of feather, but otherwise good; the most noteworthy were the first-prize Belgian cock, an excellent Silver Lizard, and, best of all, an evenly-marked Goldfinch Mule.

Any Variety.—1, H. Beldon, Goitstock, Bingley. *hc*, Rev. J. G. Milner, Bellerby, near Leyburn (French). *c*, J. Shorthose, Newcastle-on-Tyne (Brahma); C. K. Smith, Langley Grove, Durham.

Game (Black-breasted and other Reds).—1, J. Gibson, Stanhope. 2, W. & A. Boglass, Carville, Durham. *hc*, W. Bearpark, Ainderby, Northallerton. *c*, G. Braithwaite, Towlaw; W. Bearpark.

Game (Any other variety)—1, W. Bearpark. 2, J. Potts, Sunnyside, Towlaw. *c*, J. Robson, Bishop Auckland; W. & A. Englass.

Spanish—1, H. Beldon. 2, W. Bearpark. *c*, R. Wall, East Layton; F. Ridley, New Shildon.

Dorkings.—1 and *hc*, J. White, Warlaby, Northallerton. 2, W. Bearpark. *vhc*, J. F. Proud, Bishop Auckland. *c*, J. Shorthose; W. Bearpark.

Brahma Pootra—1, G. Richmond, Dalton. 2, J. Shorthose. *c*, R. Moore, Hetton-le-Hole.

Cochin-China.—1, J. Shorthose. 2, W. Barnes, Ingramgate, Thirsk. *hc*, G. H. Proctor, Durham.

Polands.—1 and 2, H. Beldon. *hc*, W. Bearpark. *c*, Miss A. Newton, Welsingham.

Hamburghs (Gold and Silver-spangled).—1 and 2, H. Beldon. *hc*, W. Bearpark. *c*, R. Moor.

Hamburghs (Gold and Silver-pencilled).—1 and 2, H. Beldon. *hc* and *c*, W. Bearpark.

Any other Variety.—1, Rev. J. G. Milner (French). 2, H. Beldon. (Black Hamburghs). *hc*, R. Moor. *c*, Rev. J. G. Milner (French); F. Jefferson.

Game Bantams.—1, W. Balmbridge, Stanhope. 2, W. & A. Boglass. *vhc*, T. Sanderson, Stanhope. *hc*, H. Pickering, Towlaw. *c*, J. Wilkinson, Towlaw.

Any other Variety.—1, H. Beldon. 2, W. Bearpark.

Ducks (Aylesbury).—1, J. Shorthose. 2, R. Moore.

Any other Variety.—1 and 2, Rev. J. G. Milner (Wild). *c*, J. F. Proud.

Turkeys.—1, W. Smith, Bondgate, Bishop Auckland.

Geese.—1, H. Marshall, Durham.

Rabbits (Any variety).—1, T. Blacklock. 2, R. Balmer.

PIGEONS.

Carriers.—1, H. Yardley, Birmingham.

Pouters.—1, W. Bearpark. 2, H. Yardley. *hc*, W. & A. Englass; T. Coundon, East Sunderland.

Tumblers.—', H. Yardley. 2, T. Coundon. *hc*, W. & A. Boglass.

Trumpeters.—1, W. & A. Bug'ass. 2, J. Kitching, Etherley (Mottled). *c*, J. Kitching (Black).

Fantails.—1, H. Yardley. 2, J. F. Proud. *c*, J. Kitching.

Jacobins.—1, T. W. Kilburn, Bishop Auckland. 2, W. Bearpark.

Nuns.—1, W. Bearpark. 2, T. W. Kilburn. *c*, H. Yardley; J. F. Proud.

Any other Variety.—1, H. Yardley. 2, T. W. Kilburn. *hc*, W. & A. Englass (Turbits). *c*, W. Bearpark.

Cage Birds.—*Canary* (Belgian).—1 and 2, J. Douglas, Stanhope. *hc*, J. Dixon, jun., Shildon. *Canary* (Lizard).—1, L. Whensley. *Canary* (Mealy).—1, W. Davies. *Any other Variety*.—1, T. Adamson. *c*, J. Dunn, Shildon. *English Song Bird* (Any variety).—1, G. Smurthwaite, Bishop Auckland. 2, J. Garry, Bondgate, Bishop Auckland. *Parrots* (Any variety).—1, J. Garry, Bishop Auckland. 2, J. Priestman, Bishop Auckland.

Judge of Poultry, Pigeons, Rabbits, Cage Birds, and Eggs, Mr. E. Hutton, Pudsey, Leeds.

NOTES ON FANCY PIGEONS—No. 14.

SHORT-FACED TUMBLERS.

The origin of these beautiful birds may be easily traced. The common Tumblers would occasionally throw better-shaped birds—birds having shorter beaks, rounder heads, fuller chests, and more "petite."

Fanciers with an eye for Pigeon-beauty would carefully preserve such, would match them together, or seek matches among their friends. Then markings and colours remarkable for regularity or brilliancy would appear, and these birds would also be mated. Hence, the eye of fanciers would be pleased, and struggles made by ardent Pigeon-lovers to produce birds of surpassing beauty in shape and colour. I am inclined to think that Tumbler fancy took a rapid spurt about a hundred years ago. Thus, Pouters were all-in-all to the fancier in A.D., 1735, and a full and excellent account of them is given in Moore's work of that date—which is good now, though it has lived more than its century—while he only mentions one kind of Short-faced Tumblers, the Almond, and of that he speaks in only a few lines—not as much as he gives about the Capuchin, and about as much as he devotes to the Narrow-tailed Shaker, two utterly worthless birds, while concerning other and now most beautiful short-faced birds, he says not one word. I do not think this silence is because Moore was not a Tumbler fancier, for his eyes observed everything, and his faithful and accurate pen omitted nothing. But mark the spurt made in thirty years. In "The Treatise" of 1765 there is a full account of

the Almond Tumbler, and the writer gives an account also of the Black-mottled Tumblers. Then came soon after Daniel Girton, and he gives four pages and a half to the Almond and other short faces, mentioning even Yellow Mottles. Then, next follows Windus, in 1802, who speaks of the Kites by name. But one thing is certain, both from the written accounts in "The Treatise." Girton and Windus, and also by the engravings, that short-faced birds had but comparatively short faces, and were as nothing to the beauties we now see. This induces me to make another remark. Sometimes we hear an expression that fancy Pigeons are not now as good as in former years. This is said either by old fanciers who have given up the fancy, or by fanciers who only judge from what they see in their own neighbourheeds.

Now, I am bound to say, having seen the best Pigeons that England, Scotland, and Ireland can show, that thirty years ago, or even twenty years ago, there were not so many good birds as now. That, as in other things, there have been improvements and advance, so in fancy Pigeons. The Peristeronic and Glasgow Shows tell us plainly that the birds and the fanciers are both higher-class than in former years.

First stands among the short faces, and ever will stand, the beautiful Almond. I may call it a choice specimen of feather and form, beauty untrained, and leaden must that eye be which can see no beauty in the shape or plumage of the little Almond. From dainty head to dainty little foot it is a lovely bird, a little gem.

But just as lovers equally admiring a fair one may differ as to their estimate of her various charms, and warmly dispute, so, alas! do Almond fanciers. As of the lady, one lover says, "Oh! it is her retrousé nose and finely rounded little head that I think so much of." Another says, "Pooh! nonsense, it is her figure that I admire; you admire a little part, I the whole." While a third may say, "You are both wrong, it is her dress which I think perfection." Just exactly so of the Almond fair one. One class is all for head and nose (beak); a second for form; a third for feather.

Now, as who is to decide when doctors differ, so, only much more, who is to decide when Pigeon fanciers differ? Please, good enthusiasts, do not throw stones either at me or each other.

It is clear that the oldest fanciers put feather first. Thus, in "The Treatise" on the Almond Tumbler, supposed to be written by Windus, and published in 1802. In this, the very first book written on the subject, the writer says in the very first page, "The first thing that strikes the eye on looking at the Almond Tumbler in the area is, the feather, or, perhaps, the shape may strike some, if that should happen to be very good; but as *I think feather ought to have the preference*, I will take that first." The President of the Peristeronic, Mr. Esquilant, also, so I believe, places feather first; and in confirmation of this view, which I own is mine, this of giving preference to the whole bird rather than merely a part—*i.e.*, head and beak, I have the pleasure of quoting the following remarks of a very able Glasgow fancier, who writes to me thus —"In Almonds, Mottles, Baldheads, and Beards, feather is the *first* point; for instance, an Almond cannot be so called unless it is of *almond feather*. The face may be ever so short, but without feather it is not an Almond. So I hold feather to be the first property. If a standard bird showing all the colours in each feather on flight and tail, and otherwise well marked on the body, then we have the *perfect* Almond. In *this* bird head and beak come second; if perfect in those, then we have a standard Short-faced Almond Tumbler.

"In the other three varieties of Tumblers, feather though it must be, is not of so much importance—they may be slightly foul, or not clean cut; and Mottles are seldom seen perfectly marked (mottled on the shoulders only). Head and beak is, perhaps, of more importance in them; still we must say to have a perfect Short-faced Baldhead, the face must not only be perfect, head and beak, but also the feather. The Baldhead must have a white head; if only half white, then he is not a Baldhead. I do not lay down the law, only I give my opinion."

No one deserving the name of a Pigeon-fancier but must be interested in the welfare of the Almond Tumbler, as for a hundred years or more it has been the prime pet and hobby of the London fanciers. A small bird, it needs but little room, and never wants to fly: hence in a small aviary or garret it can be enjoyed and cultivated to perfection. The other Short-faced Tumblers, whether Kites, Mottles, Balds, or Beards, are the near relatives of the Almond, and are very interesting. Perhaps the most beautiful—yet who is to venture to dogmatise among so many and such beauties?—is the Black Mottle. Those who were fortunate enough to be at the last Glasgow Show, will remember the pair exhibited by Mr. Fulton, and will agree with me that nothing in bird form could be more lovely.

The whole range of Short-faces are most interesting as pets, and have a hold on a fancier for life if he once keeps them. In them is no sameness, but an infinite variety of feather.

I trust that this article may lead fanciers to write more about these lovely pets.—Wiltshire Rector.

ENTHRONING A LIGURIAN QUEEN.

The arrival of an Italian queen without previous notice surprised me, for I was not in the least prepared for her coming, although I had for some time desired news of her. What was worse, she came on the morning of our annual village festival, when little attention could be paid to royalty even. At all hazards, then, I was compelled to consign her majesty to the cold and shade of the pantry for twenty-four hours, after placing a piece of honeycomb in the box. I then extemporised a queen cage of perforated zinc, about 4 inches square, and the same thickness as ordinary brood comb, into which I contrived to get the queen with her threescore of courtiers. Under the protection of this cage she was at once placed in a nucleus box with three brood combs from the nearest hive. These combs were well examined previously, and a little shaken in order to remove the greater portion of the adult bees. The box was then closed until towards evening, when a number of bees were found clinging to the outside of the cage, but with no very manifest symptoms of an attempt at regicide. Later still the bees ran in and out of the hive and touched each other, as is their wont when they miss their queen.

Next morning I determined to set the queen at liberty; but before doing so I gave the bees a little smoke, and poured some syrup over the combs. For the next two hours there was war, but I was unable to tell whether the invaders or invaded led on the attack; if the former, they were plucky, to say the least. You will be aware that I was sufficiently anxious for the safety of the queen; but at mid-day my eyes were gladdened by the sight of her walking over the combs, as if she had been resident all her life. As this is my first attempt to introduce a foreign queen, you will not wonder when I tell you that the apiary resounded with a shout enough to alarm a nervous queen. I trust she is now safe after all her wanderings by sea and land. —Clericus, *Cumberland*.

THE INTRODUCTION AND PROPAGATION OF LIGURIANS.

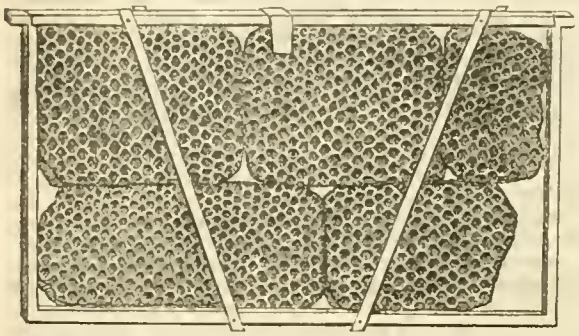
In responding to the appeal made by "T. B. H.," in page 384, of the last volume of "our Journal," I feel that I shall be compelled to trespass, in some measure, on the patience of older apiarian readers, by repeating much which has already appeared. It will, however, be evident to all, that among the constituency of a popular and advancing periodical, there must be a large and ever-increasing body of new readers, who are unable to refer to former volumes. This is especially the case in regard to the subject of the present article, and "T. B. H." is but the representative of a numerous class who urgently demand that, as the numbers containing the information which they desire are out of print, information shall be repeated for their benefit. With this demand I now propose to comply, hoping by the addition of such hints and further information as may be suggested by more recent and enlarged experience so to season my *rechauffé*, as to render it not altogether unpalatable to more advanced readers.

The first step towards the introduction and propagation of Ligurians, is, of course, the obtaining a pure stock of bees, or, at any rate, one or more pure queens; and as the purity of the original queen or queens is of such essential importance, that, unless it is secure, all future proceedings must end in disappointment, no precaution should be neglected in endeavouring to attain this end. I should, therefore, advise no one to purchase Ligurian stocks or queens of which the vendor will not guarantee their purity, whilst it is of at least equal importance to deal only with those whose known character and standing among apiarians are such as to give weight to their guarantee.

In the first place, then, I presume that no one will attempt

the introduction and propagation of Ligurians unless he possesses frame hives, and either has attained, or purposes attaining the necessary degree of facility in manipulating them. I take it also for granted, that he knows how to "drive" a stock of bees, but if not, would refer him to Nos. 139 or 357 of "our Journal," wherein my own mode of operating is fully detailed, or if he cannot refer to these, Mr. Payne's instructions in page 60 of the last edition of "Bee-keeping for the Many," may answer the purpose.

Although the attempt at Italianising with the aid only of common bees in hives with fixed combs is but vanity, and can end only in vexation of spirit, it is sufficiently easy to transfer stocks of bees, combs and all, from common hives or boxes into moveable-comb hives, where they become quite as available (perhaps more so) as if they had been hived in them in the first place. The process is as follows:—During the middle of a fine day, and at a season when the hive is well filled with bees, drive all the inhabitants of a strong colony into an empty hive, which place upon their accustomed stand, then take their original hive in-doors, and cut out all the combs whole. Fit these into frames, and support them therein by strips of wood three-eighths of an inch wide, and one-sixteenth thick, tacked at the top and bottom, two on each side of every comb, and by zinc clips at the top as represented in the annexed engraving.



Thick combs must be pared down; but take care that the cells on either side are left of equal length, and that the "partition wall" is in the centre of each bar. Crooked combs should be set straight, and if not sufficiently pliable to permit of this being done, may be slightly warmed before the fire. It will be found convenient to remove the projecting Woodbury-rib from the bars, and the bees will attach the combs to them with greater facility if their under surface be coated with melted wax. Having completed the job, and arranged the combs in the same order in their new apartment as that which they occupied in their old one, deepen the hive by the addition, on the top, of another from which the frames and crown and floor-boards have been removed, set it on the old stand, and knock out the cluster of bees into the upper hive on the top of the frames of the lower one, putting on the crown-board with the utmost celerity. Next morning take away the inserted hive, and the day after that remove the supports from all the combs which the bees have fixed. If any are not fastened, they should be left until they are also secured.

Stocks of bees with combs not less than a year old, should be selected for this operation, which must in no case be attempted with swarms of the current year, as their combs are too soft to sustain the weight of their contents without crushing when their natural supports have been removed.

(To be continued.)

IMPROVED BAR FRAMES.

There can be no question that the bar frame described in your number of July 8th is a decided improvement upon the ordinary bar-frame, and it gives "increased surface for the fingers and thumb to lay hold of;" but why your correspondent should stop short of the improvement made by "Sibert-on-the-Wold" in No. 262 I am at a loss to understand. The improved bar-frame first introduced by him has the same advantage as that of "E. B.," that "when the cover is screwed down" it holds the frames firmly in their places, even though "the hive were turned upside down." It possesses another important advantage—viz., that the top bar is elongated so as to project quite through the back and front of the hive. Any comb can be lifted from the hive with greater facility, without thrusting the finger and thumb of each hand between the combs, which to me is rather a disagreeable process; but with the elongated top bar the operation of lifting out the comb is easy and harmless, as the combs are removed from the hive by the end of the projecting bar, without pushing the finger and thumb into the hive. A comb can be lifted out, and the bees are quite unconscious of it. I lifted a comb from one of these hives the other day; upon it was the queen busily engaged depositing eggs in the cells, which her majesty continued to do all the time I held the comb in my hands—about twenty minutes. In lifting out combs from the ordinary frame hive, I am compelled to put on gloves and a veil, and otherwise to protect myself from the angry bees which appear to oppose the intrusion of fingers and thumb into their territory, while with the elongated top bar of "Sibert" I can lift out the combs without the least protection. Although I rejoice at any improvement in bee-culture I cannot but think that the bar-frame of "E. B." is rather a step backwards from that of "Sibert."

I have about twenty stocks of bees, only two of which are in hives without the elongated top bar; all the rest of my hives are fitted with Pettitt's metallic bar-rests, and it is "in the belief that it will be of use to some of your readers" that I state my experience and preference for the top bar of the frame projecting quite through the back and front of the hive.

I might state one other advantage—viz., the top bar projects about half an inch, which gives the opportunity of loosening the frames previous to their being lifted out, by a backward and forward movement before the removal of the crown board.—Sudbury.

OUR LETTER BOX.

Eggs not Hatching (*J. Hunt.*)—We have no doubt the failure of your eggs is due to the neglect of dumping them. They cannot hatch well if they are kept dry—the chicken is worn out in its endeavours to leave the shell. It is too often said the eggs were stale, and the birds are consequently weak, when the fact is, that a little sprinkling of the eggs would produce fine strong chickens. An egg that has been laid a fortnight is by no means a stale egg. A Partridge lays eighteen eggs, she takes twenty-one days to do it, and hatches all, yet some of those eggs have been laid three weeks. A Pheasant does not lay quite as many eggs, but she is as long about it, and yet hatches them all. The truth is, and in it may often be found the cause of failure, instead of being content to follow nature, we either neglect or try to help her.

Selecting Chickens (*Amy*).—If it is not inconvenient to keep them we advise you to defer classing your chickens for another month. You may safely get rid of those that have positive and visible defects, they will never pay; but as you cannot depend on equal growth, we fancy you will be a gainer by keeping the best a little longer.

Poultry for a Farm (*Farming Lawyer*).—We believe you can do much better by buying goslings and Turkey poults, than by breeding them. The latter are to be had in any number about the time the barley stubbles are ready, and so are the goslings.

Kettering Poultry Show.—Mr. Dring informs us that the second prize for chickens, "Any variety," was given to his Dark Brahmas, and not Mr. Banberry's Buff Cochins.

Turkeys (*R. F.*).—We are sorry we cannot decide the point. We have our own opinions and have often published them. We cannot see why there should be one rule for Turkeys, and another for fowls. In many parts where Turkey-breeding is an important part of rural economy, no cock is kept, but one is hired for a few days at the proper period, and that is all that is required. All the eggs prove good. We have before stated, we once shut up a hen Turkey for six weeks in a loft; at the end of that time she laid thirteen eggs, and hatched eleven. No bird of any kind had, or could have had access to her. We tried the same with a Poland hen, all her eggs were good, although laid weeks after the cock was removed. It is the same with all polygamous birds. The nearest answer we can give you is, that we believe, save under very exceptional cases, the whole laying of eggs is fertilised by the cock running with the hen at the time she began laying.

Rabbits at Spalding Show (*C. L.*).—We are unable to state either the length of the cars or the weight of the prizewinners at this Show. The catalogue forwarded to us contained neither of these particulars, nor did our reporter note them.

Sand for Young Canaries (*J. Crawford*).—Young Canaries should have sand in their cages as soon as they are taken from the parent birds.

POULTRY MARKET.—July 21.

There is difficulty in making anything like a correct report of prices. In very hot weather much poultry is spoiled, and that which from good management or contiguity to London is enabled to get to market in good order, makes a larger price accordingly. If our readers seeing this were to send, it is more than probable they would be disappointed, the weather might change, or the fowls might be spoiled.

From observations taken near London during the last forty-two years, the average day temperature of the week is 75.2°; and its night temperature 50.3°. The greatest heat was 92°, on the 1st, 1846, and 2nd, 1856; and the lowest cold 31°, on the 29th, 1858. The greatest fall of rain was 1.31 inch.

HINTS TO AMATEURS ON STRAWBERRY CULTURE.

PROFESSIONAL gardeners may be supposed to be quite familiar with the course of treatment generally adopted to secure a crop of ripe Strawberries in the early spring months, and it would be waste of time and space to further allude to it here. I shall, therefore, address myself to the amateur, who, from not being so favourably placed, either with regard to knowledge or convenience, as the gardener, often shrinks from the attempt to obtain the luxury of a few dishes of ripe Strawberries before the fruit comes in from out-door beds. Let me tell him, however, that their culture is both simple and inexpensive, and the reward, according to the labour expended, is more abundant and certain than many people imagine.

For the better information and convenience of those who think proper to adopt either system, I shall divide my remarks into the culture of plants in pots, and the culture of those planted out, taking pot-culture first.

It is necessary for very early forcing to secure the earliest runners, but for fruiting in the last fortnight of April, and in May and June, which will most likely suit the views and convenience of the amateur, the runners obtainable in the first week in July are very suitable. Prepare as many 3-inch pots, though 2-inch pots will do, as there are plants required, by first placing a small potsherd over the hole, then filling them rather firmly with soil, which, according to what experience has taught me, should be a good sound loam that has been laid up for twelve months—I prefer it heavy rather than light, moderately rich, and sifted to facilitate rooting; this done, secure every plant to the soil either by a pebble, or, which is better, a short peg made from a birch broom. Keep the soil very moist, and do not detach the runners from the parent plants until they are well rooted; then set them in the shade for a few days while they root still more. Meanwhile prepare a sufficient quantity of 5 or 6-inch pots, and shift the plants into them, using, in addition to the loam above recommended, one-third of rotten manure. The soil should not be sifted for this potting, and should be pressed firm. After this the pots should be plunged in beds of convenient size, selecting an open sunny spot upon a hard bottom, covered with coal ashes to prevent worms finding their way into the pots. The plants must have a regular supply of water, and be occasionally turned round to prevent their rooting through. They may stand here until wanted for forcing, but if frost occur, they must be protected with fern or litter, taking it off every favourable day. They will under this treatment form large crowns so firmly set in the soil as not to be moveable with the finger and thumb.

Taking the next method—that of preparing the plants for forcing without pots—select a number of turves where the fibre and the soil adhere well together, and if 4 inches thick so much the better. Cut them into squares of 4 inches, turn these turf-side downwards, scoop a little soil out of the top, and fill the hollow with sifted soil as for pots. Take them to the bed, fix the plants, and otherwise treat them exactly like those in pots until well rooted, when they may be cut from the plant. Meanwhile prepare a bed of soil 1 foot in depth on a hard bottom, and large enough to hold the plants at 1 foot apart; plunge the turves into the bed, and well water when necessary. About the last week in September and twice in October, thrust the spade to its full length midway between every plant; cut all runners off as they appear, and protect the plants from frost. If all has gone on well the roots, when the plants are taken up for forcing, will be principally confined to the piece of turf, a circumstance greatly facilitating their removal, and contributing to their success in the fruiting pit. The position for this bed of plants should be open and sunny; if possible more so than that for the pots, on account of the proper ripening of the crowns.

Having detailed the method of preparing and growing the plants, I now come to forcing and fruiting them, and as it is not often possible for the amateur to afford sufficient shelf or stage room for many of his plants, I should advise him to grow plants both ways, using the pot plants as the earliest. These when taken in should, in addition to the drainage being examined, have all the loose soil taken off the pots, substituting a top-dressing of manure and loam, one-half of each, sifted before use, and pressed firmly on the surface. When the plants are introduced into heat, the fresh roots will penetrate the top-dressing in every possible direction, and prove of great assistance at the time of blooming and setting.

If Strawberries are wanted in the end of April, plants should be introduced in the middle of January, and successionally every fortnight up to the first week in April. A gentle heat of from 40° to 45° is sufficient at first, but the temperature may be gradually increased to 55° or 60° by the time the plants come into bloom, and that temperature should be regularly maintained until ripening; they ought then to have the same temperature, but more light and air to improve the flavour. They should always have a place as near the glass as convenient.

If successions of Strawberries are to be kept up by a batch of those planted out, and there is a hot-water pit, a bed of rough material may be made up, such as will afford a gentle bottom heat. After making it of the required height, put a layer of soil 4 inches thick over the bed, then place the plants thickly, with soil around them, and well water, regulating the temperature in the same way as for those in pots. Should there be no pit, a two or three-light garden frame placed upon a 2-feet bed of heating material, such as a mixture of leaves and a little manure, will be found very useful and suitable. Elevate the frame at the back 1 foot higher than the front; plant, and regulate the temperature the same as for the hot-water pit. If the weather be fine and warm, the sun will afford sufficient heat to grow and ripen the fruit; but if cold, like the past spring, a lining of heating material may be applied with advantage.

Pay particular attention to watering during growth, and

when the plants are in bloom keep the atmosphere drier, and let more air circulate amongst them. They like a sprinkling overhead at times, and it must be regulated according to the dryness of the atmosphere. Look sharply after green fly, which, if allowed to increase unmolested, will weaken the plant, and cause much of the fruit to be deformed and flavourless.

If any vacancy is likely to occur between the forced plants and those growing in the bed, and there are any plants to spare of either sort, they may be plunged or planted in some sunny spot, well sheltered on all sides but the south and south-west; there they will come in ten days or a fortnight earlier, and be as well flavoured as those fully exposed.

With regard to varieties, they are numerous, and most people have their favourites, but I should recommend Keens' Seedling for the first, Sir Joseph Paxton second, and Dr. Hogg or British Queen last; or, if but one is required, take Sir Joseph Paxton; it is large, pink, of good flavour, and a heavy cropper.

I would advise all who have the time and convenience for growing Strawberries to try the preceding plans, and if carried out as advised, they will not be disappointed in the results. Before I had the room and other conveniences for growing Strawberries, I practised what I advised, and gave every satisfaction. A small quantity can be grown as well as a large one. —Thomas Record, *Hawkhurst.*

CULTURE OF EUCODONOPSIS NÆGELIOIDES AND ECHEVERIA METALLICA.

The free yet compact growth, handsome foliage, and abundant blossoms of Eucodonopsis nægelioides render it a desirable plant; the ease with which this beautiful stove plant may be propagated, and the simplicity of its culture afterwards, are also much in its favour. It is propagated in a similar manner to any of the Gesnera family—namely, by cuttings of the young shoots, by leaves, and by pieces of its scaly tubers. The least desirable method is propagation by the leaves, as the tubers which they produce are necessarily weaker than those formed by either of the other methods; but if a large stock is required, then leaf-cuttings are very useful. Stout cuttings of the young shoots, if made early in spring, kept shaded, and plunged in pots in a brisk bottom heat, strike root quickly, and become useful little plants in the same season. Strong tubers broken in halves throw up vigorous shoots, which form good succession plants to those produced from entire tubers. It is important to remember this, because the plants from old unbroken tubers always bloom earlier than those formed by portions of tubers, and it would therefore be unwise to put portions of tubers in the same pot with an entire tuber.

So dense may the growth of this plant be rendered by judiciously pinching the young shoots in the earliest stages of their growth, that two or at most three tubers only are required for an 8-inch pot. When the tubers are started into growth in spring they are placed in small pots, so that the plants may be shifted twice, the second shift to be into the blooming pots. If the pots are kept plunged in the bed of the stove, or in any lively bottom heat, so that the young growth is produced in a moist genial temperature, it will tend to promote free growth and healthy vigorous foliage. As the plants attain size, the pots may be lifted and placed on the side stages of the stove, or, which is perhaps better still, in a vinery at work, where, overshadowed by the foliage of the Vines, the plants continue to grow luxuriantly; and when in bloom the profusion of pretty flowers and the handsome foliage almost concealing the pots, form a lovely and attractive sight.

Owing to the hairy nature of the foliage it is necessary to endeavour to keep it quite healthy and clean, for if thrips or red spider once takes hold, it is a very difficult matter to destroy it.

No very complicated mixture of soil is requisite to grow this plant successfully; equal parts of loam, peat, and rich well-decayed manure, with a double quantity of sand and a sprinkling of charcoal, will answer very well.

The quaint appearance of Echeveria metallica, and the singularly delicate bloom visible on the surface of its foliage, are doubtless the chief causes of its popularity. Some inquiries respecting its culture have induced me to offer one or two notes concerning it. As the extreme simplicity of its culture is apparent at a glance, I shall confine my observations to its propagation.

Like most other succulent plants its cuttings emit roots freely. Cuttings are made either from the tips of the young shoots or of the leaves; those from shoots root quickly at this season in an ordinary frame or pit without artificial heat. The leaves, although not requiring a higher temperature than the shoots, do not strike root so quickly; and as, after putting forth roots, they have their shoots to form, it takes a longer time to obtain useful plants from them.

I have followed two methods when propagating this plant by its leaves; one is to insert the leaf in the soil in the same way, and to about the same depth, as with shoots; the other is to rest the base of the leaf on the surface of the soil, and support it by means of a stick and bast. This method, though rather more troublesome, is preferable to the former, as the leaves emit their shoots much sooner than those inserted in the soil. Should a number of plants be required for bedding purposes they may be quickly and easily obtained by placing in heat a few strong old plants, from which shoots will start in abundance.—Edward Luckhurst, *Egerton House Gardens.*

POTATO FAILURES.

Your correspondent, "J. W.," in your number for July 15th, appears to attribute the principal cause of Potato failures to the unusually long time from the taking-up to the planting of the seed. Upon this point I will communicate my own experience. At the outset it is right that I should observe, that I owe the system of Potato-growing which I have adopted, entirely to Mr. Fenn, of the Woodstock Rectory. In July I selected my seed Potatoes, taking medium-sized Potatoes, not thoroughly ripe. These I put in a cool place in single layers on boards, with a moderate supply of light, out of the reach of frost, and there I left them untouched till the middle of February. I then with a penknife dug out every sprout but the principal one, so as to extirpate root and branch. The interior shoots at this time were very short and scarcely visible, which is usually the case in a cool temperature. I went over the work again, where required, just before planting. On the 19th and 20th of April I planted the following sorts:—Myatt's Early Prolific, Rivers' Royal Ashleaf, Webb's Telegraph, Hogg's Early Coldstream, old Walnutleaf, old Ashleaf, Dickson's Premier, and Fenn's Onwards. All have come without a single failure, and I have dug several with as many as thirty fair-sized Potatoes to a root. I had some of my old seed left, and having a spare piece of ground, I planted some on the 3rd of July, and I now find that they are nearly all appearing above the ground. I have been over the Rectory gardens to-day, and saw there a splendid lot of Potatoes, all planted on the ridge-and-trench system, and not a single failure was observable. Mr. Fenn kindly dug up several of his own seedlings to show me, and they were magnificent. Their equal for beauty and wax-like appearance I have never seen. He then brought out some old seed, kept as specified above, in famous condition, and planted these old sets whence he had just dug early Potatoes. I may, therefore, safely observe, that seed managed as Mr. Fenn manages and plants his, will not be injured by unusually long keeping.

In connection with the ridge-and-trench system of planting, Mr. Fenn observed that he intends writing the whole subject again for the benefit of the present subscribers and readers of The Journal of Horticulture. Since visiting the Rectory gardens, I have received from Mr. Fenn a dish of three sorts of his seedlings to taste. He has named them The Rector of Woodstock, Fenn's Onwards, and Woodstock Kidney. I have tasted them; in fact, almost dined off them. I so thoroughly enjoyed them, that I may safely say that I never tasted a Potato of so fine a flavour. All were uncommonly good; but the seedling called The Rector of Woodstock, which was entirely ripe, had a flavour of such a dry and rich character that it could not be surpassed. The Rector of Woodstock is a first early round Potato, and extremely handsome.—E. Hobbs.

ORCHARD-HOUSE FAILURES.

Writing of orchard houses, Mr. Pearson says, "I have not heard of a single house without artificial heat where a crop is to be seen." We have a large house without fire heat, or any means of giving it, with a crop of Peaches, &c., in pots and on walls, and whether the said crop is full, average, or scanty, we are quite agreeable to leave to Mr. Pearson's opinion.

It is barely correct to say that the increased temperature of the cold hothouse over the open air is not the result of artificial means. Where the area of ventilation is fixed for day, night, and all weathers, there cannot, as a matter of course,

be claim to much art, any more than this year such houses can show much fruit; but where the ventilation is regulated with regard to the economisation of the sunbeams, there is considerable art, without which in this locality fruit by this means could not be had in any year.

To show that low temperatures occasionally are not injurious, it may be here observed that we have had the thermometer at 21° Fah. inside the house when the plants were in full flower, after which we never had a fuller set or better crop. We fancy —it may only be fancy—that the structural form of the house has considerable influence in this system of cultivation.—H., *Scone Palace, Perth.*

AMONG THE SWISS LAKES.—No. 1.

Not being gifted with either Musel's cloak or Fortunatus's hat, I had to pass over some seven hundred miles of land and sea before I reached the point where I was to be introduced to "the Merry Swiss Boy" and his surroundings. Now, that boy is no common boy, and he cannot be a common boy—of course I speak of a generation, not of an individual—who is born and passes his life in such a mountain land. I will not pause to argue over the why and because, but I rest upon the fact that the people of the mountains are everywhere superior to the people of their neighbouring lowlands, both mentally and physically. The Dutchman has a large posterior development, but the Swiss has a muscular leg and arm and an elevated cranium. Look at the clusters of Swiss boys, each with his knapsack, passing on, morning after morning, from every point of the compass to the canton-sustained school of the district; and from these clusters you may deduce another evidence—universal education—why a Swiss is intelligent and free.

I certainly feel equally free of pen, for when I dipped mine into the ink it assuredly was with no intention to dwell upon Swiss boys and their education, but to have made no pause until I came to my recollections and notes of Zurich. Well, here I am beneath the trees at the end of the garden of the Banr au Lac, and looking upon the lake's blue water and its bright green, villa-dotted banks. There are three English ladies and one Swiss lady near me; and this one last-named reminds me that the girls and women of this land are also physically and intellectually superior to the feminines of lowland countries. Let one instance suffice. A Swiss lady, evidently a governess commencing her annual holiday, was in the same railway carriage with me. We crossed the Channel together, went on to Paris together, and there I thought that mind and muscle demanded rest; but not so my companion. The Ranz de Vache had a spell over her, and on she went to travel without a resting over some more hundreds of miles, until she had reached the land of her birth. Well, God speed her! But before I pass from the remembrance of her fair face, and mind as fair, let me record that it is a delusion to believe that a Ranz de Vache is one especial and universally accepted melody. Every district has some favourite air, and that is its Ranz de Vache.

And now, if I can restrain my thoughts from further vagrancy, let me dwell upon subjects more consonant with the special topics of your pages. No, it cannot be; for I must jot down first something about that John James Scheuchzer whose "Itinera Alpina" is the first published of Swiss guide books—and a strange book is it. He was a professor at Zurich, this very place where my Swiss notes begin. Some ignorance of the district around does he betray, yet both he and his brother John—rare fraternity in science—were superior botanists. John devoted himself especially to the study of the Grasses, and John James to the study of alpine plants; and they are most aptly commemorated by the genus *Scheuchzeria*, for its solitary member is of grassy habit and of alpine birth. John James was a native of Zurich; he was its special physician, its professor of mathematics, and there he printed and published nearly all his numerous and voluminous works. Most of these works have one peculiarity—wherever an engraving could be possibly introduced, there one, however irrelevant and unneeded, is introduced. Thus in his "Physique Sacrée," or Natural History of the Bible, having occasion to quote the Psalm, "Who can endure the cold of the Lord?", is inserted a picture of about twenty men who suffered severely in the ice; and an allusion to some coin enabled him to add engravings of medals he had collected! Peter the Great endeavoured to lure him from his native land, but the Senate of Zurich prized Scheuchzer too highly to permit his departure. They bestowed upon him honours and stipends, and thus detained him until he died in 1733 among his fellow citizens.

His "Itinera Alpina" does not differ from his other works in having numerous illustrations, and the most interesting is his own portrait. An inscription beneath each reveals that they were added at the expense of his friends, and it startles at first to find that our Sir Isaac Newton thus contributed some, and that the portraits of plants were paid for by our botanists Bobart, Lhuyd, and Dale. With no faint interest did I examine the specimens collected by the Scheuchzers, preserved and labelled in their own hand-writing, in the herbarium attached to the Zurich Botanic Garden. This garden was established in 1560 by him who has been well named "the greatest naturalist the world had seen since Aristotle," Conrad Gesner. His collection of dried plants has been mentioned as preserved here; but it is not, nor could I learn that it had been ever, deposited in any of Zurich's public museums.

This town, like our Norwich, has been fertile of botanists, besides many high masters of many other sciences; but I will dwell only upon one other, who, like Gesner, was one of the most loveable of men—Lavater, the physiognomist, who needs no other testimony than that he would not reveal the name of his assassin, and, perhaps, it is an evidence that his countrymen think he needs no eulogy, that there is no other epitaph over his grave than this, in the obscure churchyard of St. Anne:—"J. C. Lavater's grave. Born 15th Nov., 1741. Died 21st Jan., 1801." I might not have noticed this true personal illustrator of charity, had not I long pondered over the physiognomy of organised forms which Lavater has left unnoticed—plants. They have had, however, their Lavater, for Humboldt wrote "Considerations on the Physiognomy of Plants;" but he and his disciples have confined their comments to the features imparted to a country by the plants which are there specially predominant. The Palmæ, Musaceæ, Piperaceæ, and Scitamineæ impart a physiognomy to the tropics, totally differing from that imparted by the Abietinæ of northern latitudes. But we might, I think, go some steps further; might detect the internal qualities of plants from their physiognomy. When we see a plant having the form of a Grass, whether it be pygmy, as the Poa annua on our gravel walks, or 50 feet high, as in the Bamboo, we know that starch predominates in its seeds. Again, in the large natural family of the Rosaceæ, is there one fruit that is unwholesome? or one that does not contain malic acid?

The connection of Gesner and the Scheuchzers with the Botanic Garden of Zurich impart to it a deep interest, and gladly do I bear testimony, that under the management of its present courteous, indefatigable, and skilful Curator, Mr. Ortgiss, it maintains a good position. It is not very liberally endowed; Zurich gives the ground rent free, and the Government allow £63 yearly, but the chief income arises from the collections of alpine plants, gathered together by Mr. Ortgiss during his researches among his native mountains. Those collections command a ready sale, and this source of income is consonant with the spirit of national independence; and how effective it has been is evidenced by the building and its fittings in which the Herbarium is preserved. They were paid for out of the proceeds of those sales.

One lesson was taught me by the alpine plants in this garden, which may be suggestive in cases of failure with other plants. *Linaria alpina* and *Aster alpinus*, both natives of Switzerland, pertinaciously refused to live in the garden. Mr. Ortgiss sent plants of them to Messrs. Backhouse, of York, who propagated them, and Mr. Ortgiss obtained from those well-known nurserymen some of the young plants. These flourished in the Zurich garden, and their offspring are now there, and are annually the parents of others.

Mr. Ortgiss recommends *Pterocephalus perennis* as a white-flowered edging plant. He has also a very pretty hybrid Myosotis, which he calls "Empress Elizabeth." Its parents are *Myosotis alpestris* and *azurea*. It flowers most profusely, forming a mass of intense blue, and the plant has the additional merit of producing a succession of flowers if their predecessors are cut down when fading. The term "hybrid perpetual" would not be misapplied to it.

One source of income to the garden arises from the sale of fronds of *Cycas revoluta*. The Swiss call them "Palms," and a frond is placed in the hand of a corpse, then on the coffin which encloses it, and finally is placed upon the grave. Eight francs are given for a large frond suitable to an adult, and five francs for a small frond of a size appropriate for a child.

One of the novelties in the garden was a perfectly white Gentianella (*Gentiana acaulis*). This, and many intermediate varieties, found wild on the Alps by Mr. Ortgiss, are permanent

in the Zurich garden. There are *pallida striata*, white with a blue stripe; *alba cærulea adspersa*, white sprinkled with blue; *excisa cœlestina*, white with a blue band, and several others.

It is a marvellous fact, that the American water weed, *Anacharis alsinastrum*, has found its way into the Zurich garden. Mr. Ortgies said he had taken, he thought, every precaution to avoid its being introduced; but its seed or some fragment attached to another aquatic had brought it into one of the stone tanks for aquatics.

I was much struck with the result from one mode of cultivating the Paulownia imperialis, adopted by Mr. Ortgies. Instead of allowing it to become a tree, he annually cuts it down close to the ground at the approach of winter. In the spring it throws up a stem most robust, 18 feet high, clothed to the ground with leaves 2 feet in diameter, and bearing some resemblance to a gigantic Sunflower.—G.

RHODODENDRON CULTURE.

(*Continued from page* 49.)

In continuation of the subject of soil, a very useful kind is often met with in a yellow sandy loam, not the hungry sandy soil which exists in some places, but sufficiently stiff to meet the requirements of many other plants, and which when laid down in grass is often covered with a multitude of wormcasts. Tracts of this character are found in many places, and in such there are healthy quickset hedges. I am not aware of any soil much better than this for the Rhododendron. A large extent of soil of this description exists near the southern boundary of the county of Kent, and near Tunbridge Wells and other places. It also commonly occurs in Devonshire, and I recollect Mr. Paley, the then-gardener at Mount Edgecumbe, near Plymouth, pointing out to me in the park there, the line of demarcation between it and a soil of an opposite character. On one side of this line the Rhododendron grew well, and the flowers of the Hydrangea were blue; on the other side the flowers of the latter were pink, and the Rhododendron dragged on a miserable existence. The soil alluded to does not make even a remote approach to peat, being bulk for bulk much heavier, and in no respect resembles it excepting in its capabilities of supplying the wants of the Rhododendron. Tracts of this kind of soil are met with even in close proximity to the chalk formation, for instance, near Dorking, but they are less common among great breadths of stiff clay. A mound of this kind at Preston Hall, near Maidstone, was taken possession of some years ago by the proprietor, and planted with Rhododendrons, and they thrive remarkably well. This soil, however, is more sandy than is usually met with, and I believe sufficiently moist.

Among the soils which are most to be avoided, are those containing much calcareous matter; for useful as it is to many plants, an abundance of it is fatal to the well-doing of Rhododendrons. It is next to hopeless to attempt the cultivation of the plant in chalky districts, or where limestone prevails. I will now pass on to another kind of soil which is said not to be so detrimental to the plant, and in which it is asserted by many that it will succeed well—I mean a clay soil, but I have seldom seen a satisfactory growth in soils of this class; in fact, the places are so few where any approach to success has been made in such, that I have never recommended Rhododendrons being there tried, except in cases where they seemed to be a necessity. Clays, however, differ in their chemical qualities, and some may be more suitable than others, and may answer for the common kinds of Rhododendrons, but I do not advocate an extensive plantation on a stiff clay, and to mix clays with lime, as is often done for agricultural purposes, makes the soil less suitable. A clay not containing too much calcareous matter may be improved by mixing with it yellow sand in large quantities, as the latter often contains sufficient ferruginous matter for the Rhododendron, while a bright orange sand too often contains more than enough. Much circumspection, and a knowledge of the character of the clay, are indispensable before acting in the matter. It is not easy to explain what are the features of a clay which may be converted into a fitting bed for the Rhododendron; one from which bricks are made is rarely suitable, especially if in burning those bricks shrink very much, but the stiff soils where the Brake Fern is found luxuriating may often be advantageously planted with Rhododendrons.

I have mentioned that the hard stone of the oolite formation, mingled with earth of a kindred description, often furnishes a singular but good soil for this plant; a not less suitable one is often met with where sandstone prevails, and I have seen plantations of this plant entirely amongst the refuse of a freestone quarry, as it was called in the north of England, differing merely in its component parts from the Bath stone so extensively used about London. This sandstone *débris* seems well adapted for the growth of the Rhododendron, and where it abounds the plant may be tried with every prospect of success. Indeed, I am not sure but crushed sandstone may be used with advantage in those cases where an artificial compost is necessary, or has to be added to the clays above referred to.

Other descriptions of soils might be discussed, but I have said enough to give the general reader an idea of what is suitable for the growth of the Rhododendron, or rather the soils are described in which it will thrive tolerably well, while I have attempted to point out those of a contrary description. I shall now turn to another phase of Rhododendron cultivation—one to which there has been less attention hitherto paid than to soils—and that is the rearing of plants.

Preparation of the Young Plants for Planting Out.—Simple as this may appear, I believe it has more effect on the ultimate success of the plantation than is often allowed. It is not by any means sufficient to order a number of plants from a nursery and plant them at once; such a course has seldom been so successful as desired, and a casual glance at once explains why. In general, the Rhododendron is only grown extensively in the trade by nurserymen occupying ground exactly suited to their wants, such as a good dry peat, vigorous growth being the result. Plants are ordered for some place a long distance off, and to be planted in a soil not by any means so well suited to their wants as that from which they came, and the distance being great, the carriage is likely to become heavy; to lessen the expense the ball of earth attached to each plant is reduced to the smallest size consistent with the plant's living. Now, when we take into consideration the reduced size of the ball, and the indifferent soil it is removed to, we can hardly be surprised that considerable time is lost before the plants become established in their new home, and it is not unlikely that many will die under the ordeal. This is not an isolated case; I imagine a very great proportion of the Rhododendrons obtained from the nurseries are subjected, at least to some extent, to similar treatment—not that the tradesman is in fault, for he cannot help it, and I have no doubt he would willingly furnish a larger ball with each plant, only he knows how much that would increase the charge for carriage, which for common varieties is often as much as the price he receives for them. The remedy for this state of things, especially in the case of the common kinds, as Rhododendron ponticum, is to obtain a quantity of seedlings with half a dozen or more full-sized leaves on each, and plant them out in a nursery bed, in ground resembling that which they are ultimately to occupy. After having been planted about two years they will have become bushy plants, and may be taken up with balls entire, as their removal to their ultimate quarters is not a serious affair when they are on the spot, and may be said to have become naturalised to the soil and other conditions of the place. Those who plant R. ponticum extensively for game cover or undergrowth, I cannot too strongly recommend to adopt this plan, as being the most certain to ensure success. I have practised it here for many years, as affording better-rooted plants than can be had elsewhere; and thus the roots as well as the whole plant are inured to the soil and situation they are intended to occupy.

A further recommendation in favour of the foregoing method is, that in places where rabbits are very numerous, few, if any, plants escape their destructive propensities, and it has often been asserted that Rhododendron ponticum is proof against them, but those who make the assertion have, perhaps, never witnessed these prolific marauders in such numbers as are met with in some localities, or they would have seen that this plant, though suffering less than many, is not exempt. I have often been led to think that where new plants from a distance are brought near rabbits they are the first to suffer, while those of home-growth escape. I suppose it is the novelty that accounts for the greater injury done; but I do not mean to assert that the home-reared plants all escape, but they certainly suffer less than imported ones; besides which, it very often happens that the latter have been growing more closely together than the others have, and a more delicate set of side branches may in some degree account for it. I think it is but seldom this plant is partaken of as food, but the evil is quite as great if the shoots are bitten off and the plant either injured or destroyed.

As I only intend to explain the main points in the cultivation of the Rhododendron, it is not necessary to enter into details respecting the many varieties now grown. Persons who are doubtful of the soil or situation suiting them, had better begin with the common kinds first, and the very commonest, R. ponticum, is not without its merits. I question much if any of the others is so generally serviceable. In habit the plant is excelled by none of them; its foliage is good, it remains as long in flower as any, and is said to thrive where others do not. Of the latter property I have some misgivings, as many of the hybrids thrive as well as ponticum in a soil said to be unfavourable. It certainly is the hardiest, and it reproduces itself from seed with greater facility than most others. Old plants surrounded by weeds as high as themselves, scatter their seeds, and then become plants amongst the rubbish, and with more certainty than if the seed had been deposited in a prepared bed in the kitchen garden. Rhododendron ponticum also varies in colour, and a mass of it in flower is, perhaps, shown to best advantage when it is surrounded by tall grass just fit to cut for hay; the rich tints of the Rhododendron slightly overtopping the various grasses just ready for the scythe, give an air of vigorous health, which the closely-shaven lawn fails to do. More choice varieties may, perhaps, deserve a better-kept position, but those who have witnessed it in the rougher one, will, I think, say I am right. It would not be well to allow long grass to usurp too much of the ground occupied by these plants, but to keep their collar free from weeds or rubbish of all kinds.

In forming a collection of the best varieties of hybrid Rhododendrons, it often happens that too great a proportion of those selected are of the rosy scarlet section, of which Mrs. John Waterer may be said to be the type, while but few are white. The latter colour is, in my opinion, the most valuable in a Rhododendron; for it contrasts best with the dark green foliage, and in the majority of cases where this shrub is grown, the eye of the beholder rests on a mass of foliage as a background, against which white flowers stand out in relief; in fact, white flowers, as a whole, are never too numerous. Whoever yet found fault with a white Camellia? and the sooner we can have a Rhododendron to match it the better, adding at the same time the strong waxy substance of corolla that some of the Himalayan species possess. The latter ought to be more extensively tried in favoured situations, as they have not yet been sufficiently hybridised with better-known kinds, in order to transmit their desirable properties to their offspring. It is only in favourable situations, however, that it would be advisable to try many of these distinct species.

The better-known Rhododendrons are likely to succeed in a soil and situation falling short of what may be called first-class; but most of the varieties generally called "hybrids," including the bulk of the named kinds, may be grown in soil such as I have described, and, as a class, they afford, perhaps, as great a display of floral beauty as anything in the gardening world, not even excepting the gorgeous Indian Azalea and the bedding Pelargonium, while as evergreen shrubs they are exceeded by few in point of long-continued beauty. R. ponticum, at least, may be said to be one of the hardiest plants we have in its capacity of enduring our winters, and most of the hybrids are equally so. I hope, therefore, where opportunity offers, that the cultivation of this plant will be extended, and that groups of it will be planted in woods and other places from which cattle are excluded. For lining the sides of drives, or roads through similar places, no plant can be more appropriate, for where the soil is suitable, and it has had a fair start, it generally maintains itself against most ordinary vegetation. Wastes devoted to the rearing of game might also have a few specimens of this plant, not scattered singly, but arranged in groups; and if they were looked after for a year or two at starting, they would take care of themselves afterwards. It is in such wastes that it thrives best; a trial of it is there well worth making. The sites for this plant are so many, that there are few persons having the means, who might not find a situation in which to try it and have the pleasure of unexpectedly meeting with a clump of this plant, say at the end of May, when it is in flower.

Much more might be said in favour of this plant, and places pointed out where it forms one of their most important attractions, witness the gaiety of certain portions of the London parks when this plant is in bloom. In their case, however, I expect the bed is prepared at considerable expense; but there are plenty of places where it would do better than it ever does there, if a little attention were paid in starting it. In many places it is almost naturalised, the plant ripening its seeds and disseminating them in all directions, young plants springing up by the thousand. Amongst those who had the good taste to plant the Rhododendron extensively when it was scarcer than now, one of the former owners of Cobham Hall, of which an account was given in the last volume of this Journal, deserves to be particularly mentioned. There a dry peaty wood had been divided into compartments, and the side of the walks or roads lined with this shrub, probably nearly a century ago. The soil and situation suiting them, the Rhododendrons have reproduced themselves in such numbers, as completely to occupy the whole space, the roads only being kept clear, and a mass of fifty or one hundred acres presents a display of beauty in the season which few places can boast of. As the plant is now at least a hundredfold more plentiful than it was a century ago, those desirous of presenting futurity with a similar sight, can accomplish the object at much less cost. I hope, therefore, to see many waste places ornamented with groups of this plant, which, besides its beauty, is valuable as affording shelter.—John Robson.

JUDGING CUCUMBERS.

We have been applied to by several correspondents for some rules applicable to deciding the comparative merits of Cucumbers exhibited to compete for prizes. We are not surprised at such applications, because there is often great and just dissatisfaction when a huge brace, thicker than a man's wrist, 20 or 24 inches long, yet yellowish at the ends, and so flexible from keeping that if held in the middle the ends would bend down far towards meeting, are passed over for a neat perfectly-fresh brace, green throughout, not much above a foot in length nor more than 1½ inch in diameter. To the latter we should award the prize, for they would be far superior in crispness and sweetness. To meet the wishes of our correspondents we reprint from a former volume of our Journal the following:—

1. The first essential is that the brace of Cucumbers be young, fresh, and green.

2. Both the Cucumbers forming the brace should be straight, and the one a counterpart of the other in thickness and length.

3. Though young and crisp, the fruit should be sufficiently grown to be free of anything like deep sutures along the sides, as these involve as much loss in preparing for table as deep-eyed Potatoes.

4. The shorter the shoulder of the Cucumber and the more distinct it is the better—that is, no blending of the shoulder with the general length of the Cucumber, but that general length or gun-barrel part should start with an abrupt roundness at once from the shoulder, and proceed with the same diameter until it ends as abruptly at the point.

5. It is well that the point should be quite green, and if the blossom be attached to it all the better. If the bloom on the Cucumbers is fresh from end to end an extra point will be gained.

6. As respects proportion, nine diameters used to be considered a good proportional length; and hence a well-grown symmetrical brace, 9 inches in length and 1 inch in diameter, will have many admirers. We would prefer for longer Cucumbers that the diameter should be a little less proportionally—that is, a little less than 2 inches for 18 inches in length.

7. We have kept length to the last, but it will ever form a favourable item in judging, when united with freshness and symmetry. Shorter fruit will win, if shown against long, only when more fresh, more symmetrical, covered with richer bloom, &c.

STONE BLOCKS FOR ORCHIDS.

I am not aware that the acknowledged authorities on this beautiful family of plants, who have favoured us with a revelation of the secrets of their art in the successful culture of the various species of Orchids, have ever spoken of stone as suitable material on which to place those which are generally recommended to be placed on blocks of wood. Neither have I any recollection of ever having seen epiphytes with a stone to feed upon. This material may, however, be used beyond the range of my observation. Be this as it may, my present object is not to recommend stone blocks as the best sort that can be used, nor to say that I have, from any lengthened experience, found any advantage in using stone instead of wooden blocks, but simply to state that about a month ago I had to look about for a few suitable blocks for Orchids, and could not conveniently find

them; and as is often the case in gardening, where a way cannot be found it has to be made, and so a few soft freestone blocks were hewn into shape something like small sugar-loaves, and placed a few inches deep in pans filled with soft water. On one was placed a sickly plant of Phalænopsis amabilis, and on others plants of Aërides Lobbii and A. Dayanum. The first named of these especially had not a fresh root, and just one leaf, when placed on the cone of stone. They were simply fixed in their places with a piece of matting, and a little fresh sphagnum placed round their collars. The Phalænopsis has now three fine healthy leaves of a dark green colour, and is rooting and growing vigorously, and clinging to the stone with immense roots, which are covered with a gelatinous substance, the sign of health. The same may be said of the Aërides.

The soft freestone, by capillary attraction, keeps itself always full of moisture, and it is, moreover, a good absorbent and conductor of heat; and, so far as my observation goes, it appears a material worthy the attention of Orchid-fanciers. Soft freestone can be cut into such a variety of shapes that a house of Orchids might be made to look much more picturesque than they are generally met with.—D. Thomson (*The Gardener.*)

THE MERITS AND SHORTCOMINGS OF THE ROYAL HORTICULTURAL SOCIETY'S

MANCHESTER SHOW.

In taking a retrospect of past events, there are comparatively few in which some improvement does not seem capable of being made, and however frequently the same thing may be repeated, the same observation often holds good; for something at one time is different from what there is at another time, rendering a departure to a certain extent from the former course necessary. The arrangement of horticultural shows is no exception to this rule; the stereotyped course of those held in the metropolis cannot in all cases be followed out in the provinces, while a too lax regard to principles entails confusion and disappointment. But it is thought that experience ought to obviate this, those having the management of such gatherings benefiting by the practice of former years, yet such is not always the case, as was witnessed at the late Manchester Show, where a schedule of prizes, liberal to a degree which only a wealthy city like the cotton metropolis could put forth, was expected to bring together the best horticultural produce the kingdom could furnish. Many good things were sent there, yet the Show as a whole fell short of what it ought to have been, and what the donors of prizes had a right to expect. This, no doubt, is attributed to different causes; one of which, and perhaps not the least, was the diffidence of many exhibitors, who declined showing, under the impression that the liberal prizes offered would call up an opposition which would leave them no chance, and numbers acting on that opinion left the competition in many instances to comparatively few; consequently, as I heard an experienced exhibitor declare, "Many of the prizes were literally stolen."

Now, this is not as it ought to be. The patrons of a show, and there were a great many such at Manchester, had a right to expect some compliment paid them. In some classes this was certainly the case, but it was by no means general, and for this exhibitors are unquestionably to blame. Then comes the other side of the question, Did the managers of the Show perform their duty? I fear only one answer can be given to this, and that a negative one; for as one of the local papers expressed it, "The whole denoted roughness, no attempt being made to conceal the fact that it was held in a pasture field; the long seed stems of the grass remained uncut, embellished at least up to Monday evening with a plentiful supply of shavings and other litter." Certainly some parts of the ground presented the appearance of having been levelled, and the parched character of the sods so thrown down could not be mended; but why delay the erecting of the vegetable tent till after the time the cards intimated the public were to be admitted?

Many other delays seemed unaccountable to those who have witnessed punctuality and order elsewhere. An entrance, imposing enough, admitted the visitor into a square or oblong piece of ground, one side of the entrance being devoted to the stands of horticultural-structure builders, implement makers, boilers, and the like; the other side contained the tents for the plants and fruits, while in the immediate front, and that, too, at but a few paces from the entrance, were some empty plant vans of no prepossessing appearance! The arrangement of the various examples of hothouses and the like was all very well, and a spacious refreshment tent was also well placed, but the tents for plants presented a sad disregard to order and appearance when compared with those in the agricultural department.

A large circular tent, which might with some propriety have occupied a central position from its height and importance, was placed at one side, while a long narrow one for Orchids and similar plants occupied a sort of valley at one side of the ground—an arrangement not to be complained of, perhaps, since shelter and exemption from draughts are so necessary for these plants. The other tents were also long ones, and certainly too narrow. In one of these the fruits were arranged on a table along the centre, with some other things; in the others were the plants of various classes, as well as in the large circular tent before alluded to.

Beginning with the large tent, it may be explained that a circular stage occupied the middle, on which were placed some of the best plants of the Show, being the collection of mixed flowering and fine-foliaged plants from Mr. Baines, gardener to H. Micholls, Esq., of Bowdon, and others; while around the sides of the tent were collections of Ferns and handsome-foliaged plants, standing on the grass and without any protection whatever from the intrusion of a crowd, unless some short stumps about 6 inches high could be called a guard, but they also tripped-up the visitors, and I had the good fortune to save a lady from falling into a very fine Sanchezia which stood near the edge. Surely a rope of some kind ought to have been placed.

The fruit was equally unprotected, the public being allowed close access to the tables. Now, in making this remark, I by no means wish it to be inferred that any intentional damage was done so far as I saw, because the number of visitors was not great, and to their credit they scarcely touched anything unless it was a card; but if the crowd had been greater it would have been impossible to have avoided injury to something, however careful and well-intentioned the whole of the visitors might have been. A rope at a short distance would have been a relief, even to those nearest the various objects exhibited. Witness a bevy of young ladies four or five deep bending over and scanning with critical eye the beauties of the ball and bridal bouquets, while paterfamilias behind them, perhaps more rude in his anxiety also to gratify himself, forces the front lady against one of these fragile beauties, and an injury, if not an upset, is the result. Are the managers not to blame to leave such tempting objects of inspection so unguarded? A stand of skeletonised plants or foliage in the same neighbourhood was wisely enclosed in a glass shade. Further on the fruit were objects of equally anxious scrutiny, and the natural desire to ascertain the names of the exhibitors, led, perhaps, to some unintentional damage here by the cards being so frequently lifted, and in this case a very grave and serious blunder was committed by the managers of the Show not employing some one to write them whose penmanship would have informed the passer-by where such things came from at a single glance, instead of necessitating him to take up the card and make it out as best he could; for the handwriting certainly did not exceed that of ordinary correspondence. Good penmen are assuredly plentiful enough to be within the reach of the means of the Society, whereas the handwriting of the exhibitors' cards was, perhaps, the most difficult to read that was ever seen at any exhibition. In the vegetable tent, I heard more than one argument held as to whether the card represented the contribution of one or more dishes, the writing and figures being so indistinct, and there were no divisions of any kind between. A dozen or two yards of red tape, much as it is despised figuratively, might have been advantageously used here, by tacking it on the table to divide the classes, and the same might have been done amongst the fruit and plants. Perhaps this might be done at a later period of the Show; but there is no excuse for the indifferent character of the writing on the cards, which, I believe, were written some days before, but certainly in such a way as would have met with a severe rebuke from the critics of the London shows some twenty or thirty years ago.

Let us turn to other pleasanter aspects, and as the main features of the Exhibition have been commented on by others, only one or two minor matters will be mentioned here, the first of which is, that all praise is due to Mr. Barron, or whoever sent the contribution of Fig trees in pots from the Royal Horticultural Society's garden. I should much like to see the same pots when the fruit is ripening. The pots of Vines in

bearing, as well as those prepared for next year, from Mr. Meredith, were also good, and only elicited a regret that Mr. Meredith's name was not amongst the competitors for fruit prizes. A collection of Grapes from Mr. Thomson, of Dalkeith, was also remarkable, as being the produce of Vines only planted last year, and some of them from eyes of that same season. The bunches, though not large, were good, and well ripened, being shown as examples of what a heated border was capable of doing, as Mr. Thomson is an advocate of that plan. Certainly the Grapes were good for such young Vines, but it is late in the season now to ascribe merit to underground heating; as examples, however, of skill in showing how soon after planting good Grapes could be produced, they were meritorious. A good bunch of the Golden Champion also accompanied them, not ripe, it is true, but simply to show the character of the Grape, which has a good-shouldered, compact bunch, berries very large and almost globular, and in flavour (which I ascertained elsewhere) it is somewhat of the character of Chasselas Musqué, but many times larger in berry. Some very good specimens of Vines in pots came also from Messrs. Lane, of Berkhampstead, as well as some other fruits in pots in a bearing condition, but the Grapes were undoubtedly the best.

Outside the tents were groups of Coniferæ, in pots, tubs, or baskets. Some of them had apparently only been recently removed from the ground, and suffered accordingly. Several of the more choice species, as well as some Japanese and other shrubs of recent introduction, were accommodated inside; the blanks rendered unavoidable by those who bespoke space, and did not send plants, being judiciously filled up in this way, and yet there was room.

One feature of the Manchester Show, which I believe has been adopted for some years, and is now followed by others, is to give prizes for a mixed collection of flowering and fine-foliaged plants, the judicious mixture of the two being more agreeable to look upon than either alone. Mr. Baines's collection had a decided advantage in this respect over those he was opposed to, but in some other classes the difference was less perceptible, while in the case of fruits it was, of course, in some cases difficult to decide; but it is not the purpose here to criticise the judgment, for I believe the decisions were not arrived at without much trouble and difficulty by those engaged, and I am not sure if they were completed until several hours after the public had been admitted. Here, again, the managers were at fault, and, no doubt, the judges felt annoyed at their position; in fact, the early part of the day was spent in the leisurely way that indicated everyone was making a holiday of it for himself, regardless of that important aggregate—the outside public knocking at the gates soon after midday. An energetic master mind such as Manchester surely possesses in many other matters, was certainly wanted here to push the thing on. The many highly creditable productions of horticultural skill would not then have been huddled together without order or design, and the public, by far the most important persons concerned in such matters, would have felt as much pleasure in viewing the productions presented to them at a distance of 2 feet further off, had they the means of ascertaining who were the exhibitors, and what honours they took; whilst, as before stated, if the visitor wished to satisfy himself on the latter point, he had to take up the card and make out, if he could (for some failed in doing that), the name of the exhibitor, and the class he exhibited in. The latter part of the information might as well have been printed. As it was, considerable time was spent in making it out.

Turning, again, to more pleasing parts of the Show, the samples of horticultural structures of glass were good, and those samples of ground vineries, as they are called, were ingenious. Boilers of various construction were also shown, some evidently capable of performing a large amount of work; but the condition of the ground rendered it impossible to employ the mowing machines, which were exhibited in numbers. The preceding, garden engines, syringes of several makes, and various other articles, constituted an attractive whole. I also noticed flower pots, and modes of hanging them up to poles, walls, and in other positions by prepared wirework of a simple design, while a large stand of fancy articles displayed the all-important croquet materials, and the scarcely less important, but most likely more transient rage of the time—the bicycle. The music-stands were plain, unassuming structures, one of them not being finished till late in the day of opening.

It would be wrong to conclude without giving credit to whom credit is due. The vegetable tent was well filled, and that, too, with productions of a creditable kind. Celery in a blanched condition, ripe Tomatoes, Scarlet Runner and Kidney Beans, with all the common vegetables, were in abundance, the only thing wanted being some marks indicating whether the articles exhibited were single dishes or collections of a certain number. This, and the careless handwriting, as an experienced exhibitor was heard to remark, rendered the whole a mass of confusion, and spoiled what otherwise would have been a good show. Let us hope, if the Royal Horticultural Society unite its fortunes to its more robust sister another time, it will appoint officers of more experience than those who directed its affairs this time, for the patrons of a show like that at Manchester ought to expect a different state of things from that presented last week, and the public also look for more information, while, perhaps, the party having the greatest cause to complain is the exhibitor. Let us hope the like will not be repeated next year. —A Correspondent.

ROSES, STRAWBERRIES, AND POTATOES AT OKEFORD FITZPAINE.

By a fortunate coincidence of circumstances I was enabled (July 2nd) to pay a long-promised visit to Okeford Fitzpaine; and as my arrangements permitted me to accept Mr. Radclyffe's hospitable offer of a bed, I had ample time to note down fully the most remarkable features of this remarkable place.

First, as to Roses. Of these Mr. Radclyffe has 1900 plants, mostly on the Manetti stock. Charles Lefebvre and Jules Margottin he still grows in great numbers. I was particularly struck with an oblong bed of Empereur de Maroc, as also with one of Souvenir de Malmaison, which does not seem to wait here, as elsewhere, for the cool autumnal nights to flower in perfection. One bloom measured 5 inches in diameter. Of the more uncommon kinds I noticed splendid specimens of Baronne Pelletan de Kinkelin, Baronne de Maynard, a pure Camellia-shaped white; Felix Genero, Madame Clémence Joigneaux, Madame la Baronne de Rothschild, Maréchal Vaillant, Marie Baumann, and Pierre Notting. Mr. Radclyffe is much pleased with Lady Suffield, a Rose new to me, although sent out four years ago by Mr. William Paul. In colour it is purplish crimson, in form perfect, and in habit robust. Growing side by side with other strong kinds, it has proved itself superior to them through this trying season.

Of Strawberries, there were fine beds of Frogmore Late Pine, Cockscomb, Dr. Hogg, and Lucas. Mr. Radclyffe makes a great point of setting-out runners as early as possible. I saw some which had been in the ground by July 1st doing well. We had some Alpines (the Galande variety) for dessert, and delicious they were. Your able contributor, "R. F.," would do well to grow them (if he does not already), as the birds never touch them. The Peach and Nectarine trees had not much fruit, but marvellously healthy foliage.

A large space is allotted to Potatoes, and very noteworthy among them was Thorncroft's Seedling, a strong-growing kind, with golden-tinted foliage. We had Rivers' Royal Ashleaf as good as ever for dinner, as also McLean's Little Gem Pea, the earliest wrinkled variety, and of excellent flavour.

Mr. Radclyffe is no miser over the treasures which he possesses. His gardens are thrown open freely to all who like to visit them. As many as 297 people in one day have availed themselves of this privilege. May he live long to enjoy his well-earned reputation, and impart to a grateful world from his vast stores of horticultural knowledge.—A. Middleton, *School House, Kingsbridge.*

EARLY PEACHES.

Pray allow me the indulgence of correcting my errors, owing entirely to my writing crabbedly and hurriedly. In paragraph 1 (page 57), I should have added after "England" "where only one now grows." In paragraph 3, after "curious," I should have said "creation," not "creature." Allow me also to add that the Early Beatrice Peach has small kidney-shaped glands and large flowers. The Early Louise Peach has small kidney-shaped glands and small flowers. Both are white at the stone.

I have to-day (July 22nd), gathered the last of my fruit of these two kinds from some fine trees in my cold orchard house. They were dead ripe, and measured respectively 7½ and 8½ inches in circumference; the Early Beatrice will not, therefore, prove a small Peach when well cultivated. Its colour was

deep crimson over its whole surface, and its flesh was also tinted to some depth with the same colour.—Thomas Rivers.

THE ROYAL HORTICULTURAL SOCIETY'S MANCHESTER SHOW.

Table Decorations, Bouquets, &c.— The table decorations, as well as the bouquets, shown at the Manchester Exhibition, though not so numerous in the former case as in the latter, were well arranged and attracted considerable attention, especially from the female portion of the company. First and second special prizes were offered by William Wilson, Esq., and a third prize by Mr. John Shaw, for a vase epergne, or centre-piece for the table. As much of adverse criticism was passed on the judgment in this class, we may announce that the Judges were the Rev. S. Reynolds Hole, Cannton Manor, Newark; Mr. William Ingram, the Gardens, Belvoir Castle, Grantham; and Mr. Charles McDonald, the Gardens, Woodstock Park, Inistioge, Ireland—men whose very names would be an assurance that they would take to such a judgment as this all that cultivated good taste required to be applied. The first prize was given, and most deservedly, to Mr. R. S. Yates, Sale, Cheshire, for a stand of flowers that was to some extent a happy breakaway from the somewhat stereotyped form of the Marchian designs to be met with at almost every exhibition. The stand was an elegant design in silver, of a Palm supporting a shallow Grape dish, and in this was most tastefully and elegantly arranged a splendid bunch of choice flowers, the apex being formed of a spike of the pure white Crinum giganteum, with Oncidium, white Moss Roses, Gardenia Fortunei, Lælia purpurata, Allamanda Schottii, Stanhopeas, Stephanotis floribunda, relieved by and interspersed with fronds of Ferns, &c., and having flowering-shoots of Stephanotis floribunda falling away from the base of the bunch in "admired disorder." There was a happy combination of elegance, beauty, colouring, and proportion, and they who so bitterly cavilled at the judgment, must have had a slavish regard for mere steorotyped designs after the Marchian model. Moreover, the elegant arrangement almost hid the base of the stand, and it was solely a splendid bunch of flowers most tastefully arranged, quite "a pretty dish to set before a king."

The second prize was awarded to Mr. J. Delamere, Oxton, Cheshire, who had a pedestal supporting two glass dishes, one almost at the base of the design, the other near the top. The pedestal or base of the design was lined with the silvery-variegated Acer negundo, and leaves of Wistaria sinensis. The flowers in the glass dish rested on a base of Lycopodium, which served as an edging, and was composed of Roses, Fuchsias, Gloxinias, Pelargoniums, Bougainvillea glabra, elegantly intermingled with shoots of Lonicera aureo-reticulata, and leaves of Caladium Bellaymei, C. argyrites, and Cissus discolor. The apex consisted of a vase of Adiantum cuneatum. Unfortunately for the Judges, the intense heat soon told on the flowers, &c., and by the afternoon this design looked pitiable indeed. It was past the stage of criticism. No doubt it must have been a praiseworthy design when first arranged.

The third prize went to Mr. W. S. Dobson, of St. James's Street, London, and it was respecting this stand a great deal of unpleasantness occurred. It was an epergne of the Marchian type, having a large base filled with flowers, the centre being a kind of circular looking glass, from which rose at the sides three small bouquet-holders. From the centre of the glass rose a glass support, bearing at the top three small glass baskets in the form of an inverted cone, suspended by glass rings. The base of this design was somewhat elaborately filled with flowers, consisting of red and white Roses, Phalænopsis amabilis, Oncidiums, Picotees, Gardenia Fortunei, and other fragrant flowers; these being relieved by Fern fronds, &c. The small glass vases were filled with small bouquets of Orchids; and the baskets suspended from the top filled with Oncidium, Stanhopea, Stephanotis floribunda, with small bits of Fern fronds. At first sight the eye was much attracted by this arrangement, perhaps to a great extent because it was a copy of the style we have been accustomed to regard as the *ne plus ultra* of dinner-table decorations. A second look took in the fact of how much the design owed to the stand itself, and then there followed the impression that there was a commonness about the vase, while it was utterly out of proportion to the rest of the design. The longer one looked at it the less one liked it; on the other hand, the design to which the first prize was awarded grew in favour as it was more minutely examined; and in connection with this it may be remarked, that it were much better the decisions of the Judges were regarded as final on these occasions. It did appear to betray a great want of courtesy to their brethren, that two other Judges should have gone down to the tent containing these decorations and there openly insulted the decision of their fellow censors while the tent was crowded with visitors, to the subversion of good order, as the other exhibitors placed first and second could not but feel aggrieved at the reflections so openly cast on the judgment.

In the awarding the prizes for two bouquets for the hand in Class 36, some confusion occurred owing to the two best bouquets having been overlooked by the Judges. These came from Mr. J. Delamere, Oxton, and eventually they were awarded equal first prizes with those exhibited by Mr. R. S. Yates, Sale. The bride's bouquet, exhibited by Mr. Delamere, consisted of Phalænopsis amabilis, Stephanotis floribunda, white Jasmine, and small white Roses, most elegantly intermingled with bits of scented Pelargoniums and Adiantum cuneatum; the base was formed of Pteris serrulata and leaves of Caladium argyrites. The ball bouquet consisted of a centre of red Roses, around which was Stephanotis floribunda and light Fuchsias, and towards the base erect-flowering Gloxinias, Bougainvillea glabra, high-coloured French-spotted Pelargoniums, white Orchids, Roses, &c., the flowers resting on an edging of Adiantum and leaves of Cissus discolor. These bouquets were elegantly proportioned and exquisitely arranged. The bride's bouquet shown by Mr. R. S. Yates was composed of Gardenia Fortunei, Eucharis amazonica, Stephanotis, white Tea Roses, and Crinum, resting on a base of Adiantum and leaves of the Orange and Caladium argyrites. Among the flowers were, dotted here and there, sprigs of the white-flowering Hoteia japonica. The ball bouquet was composed of the Crinum, red Moss Roses, Stanhopea, Stephanotis, yellow Tea Roses, Lælia purpurata, with scarlet Tropæolum in small clusters, resting on a base of Davallia and Adiantum. The composition of other bouquets in this class need not be particularised; and of the bouquets shown by amateurs, it may be said that they did not call for special remark.

Of the special prizes given by Mr. H. Birley, M.P., for eight varieties of cut flowers, the first was taken by Mrs. E. Cole & Son, of Withington, and consisted of Ixora coccinea, I. Colei, a handsome white species, Kalosanthes punicea, Eucharis amazonica, Dipladenia crassinoda, D. amabilis, Allamanda grandiflora, and Erica venosa. These were arranged on a Dahlia stand for twelve flowers, and the exhibitors filled up the vacant back row by adding specimens of four forms of Ixoras—viz., javanica, amboynensis, Alexandrina, in the way of amboynensis, and having orange flowers spotted with crimson, and salicifolia. Altogether this was a most interesting and instructive stand of flowers. Mr. R. S. Yates was second with flowers somewhat roughly arranged in a deal box, and comprising Crinum giganteum, a showy Amaryllis, Oncidium flexnosum, Cattleya Loddigesii, Gardenia Fortunei, &c., &c. Third, Mr. S. Barlow, who had some nice flowers arranged in an ornamental flower pot.

New Florists' Flowers.—Scarcely so many flowers as might have been expected in so renowned a plant district were submitted to the Floral Committee. Messrs. Downie, Laird, & Laing staged some of their new Gold and Bronze Zonal Pelargoniums, to one of which, a finely-marked variety by the name of Impératrice Eugénie, a first-class certificate was awarded. It has a golden leaf ground, a reddish chocolate strongly-marked zone, and in the character shown will make a most effective bedding variety. Mr. C. Turner, Slough, received first-class certificates for Picotee Admiration, a heavy rosy purple-edged flower of the finest quality and fullest substance, the petals large and stout; and Miss Turner, a medium light rose-edged flower, full, and finely marked. First-class certificates were awarded to Mr. C. J. Perry, Castle Bromwich, Birmingham, for Verbenas—Rising Sun, glowing salmon red, with small white eye, surrounded by a rich deep maroon ring; and Butterfly, warm flesh, with a striking crimson ring round a pale eye: two flowers that fully sustain Mr. Perry's reputation as a raiser of new kinds. Mr. Perry had also the Rev. S. R. Hole, R. H. Vertegans, Ada King, Rev. J. Dix, and others, of which something will be said by-and-by. The deceptive properties of light were somewhat singularly illustrated by a new bedding Lobelia, named Favourite, furnished by J. Taylor, Esq.; under canvas, and in the very subdued light, it had the appearance of a deep violet hue, in which form it would have proved a distinct and valuable variety. When exposed to the full glare of light outside the tent, the charm was dispelled, and the ordinary form of a dwarf-growing blue bedding Lobelia was seen. Mr. F. Perkins had some blooms of his new Perpetual Picotee Prince of Orange, which fully maintains its high reputation; and Mrs. E. Cole & Sons had their showy Ixora Alexandrina, described above. The other subjects were but of small interest.

Vegetables.—The show of Vegetables was on a tolerably extensive scale, one large tent being entirely filled with them. Many good examples were shown from the gardens of the rich nobleman, as well as from the plot of the humble cottager. Vegetables, however, although they are the most important and useful of the products of a garden, never receive at an exhibition that amount of attention or admiration to which they are justly entitled. They are to the general visitor certainly less attractive in appearance than flowers or fruit, and we can thus understand how he should pass them by. We are, however, at a loss to understand why so many gardeners themselves, who understand the difficulty and importance of their cultivation, should take so little interest in their exhibition. The present season, so far, has been tolerably favourable for the growth of vegetables.

Peas, the king of vegetables, were shown largely and well; Laxton's Supreme taking the lead a long way for size, length of pod, and beauty of appearance. Messrs. Carter & Co., who hold the stock of this Pea, exhibited the same in fine condition, and some half a dozen other varieties—viz., Laxton's Quality, Laxton's Quantity, Laxton's Fine Flavour, Laxton's Manifold, all so nearly resembling one another, and inferior to Supreme, as to be altogether undesirable. Carter's Hundredfold seems to be a fine variety, although much in the way of No Plus Ultra. Celery, although Manchester is the head-quarters for the cultivation of this esculent, was not so well shown as might have been anticipated. Turnips and Carrots were, in general, particularly clean and fine. Cabbages were, as a rule, poor, and very few were shown.

Potatoes were clear and good, and some good Onions were also shown.

In Class 38, for twelve dishes of vegetables, the first prize, a silver cup of the value of five guineas, was offered by Sir James Watts; the second and third by Messrs. T. Green & Son, of Leeds. Mr. D. Lumsden, Bloxholm Hall, Sleaford, was placed first for a very excellent collection, in which was a splendid tray of Laxton's Prolific Long-pod Pea, Prince of Wales Kidney Potato, good Cauliflower, White Dutch Turnips, Short Horn Carrots, Tripoli Onions, Broad Beans, Kidney Beans, Dale's Conqueror Cucumber, Globe Artichokes, Giant Green Orach, and the Rat-tail Radish. Mr. J. Smith, gardener to H. K. Balstone, Esq., Hallcar, Altrincham, was second; his collection contained excellent Celery, very fine Tomatoes, Mushrooms, Vegetable Marrows, Carrots, &c. Mr. J. Stevenson, Lark Hill, Timperley, and Mr. Dennis, gardener to K. H. Ainsworth, Esq., were placed equal third, all with good collections. There were in all thirteen competitors.

In Class 39, ten dishes of vegetables, the prizes were offered by Arthur H. Heywood, Esq., the Proprietors of the *Manchester Examiner and Times*, and Mr. John Shaw. Messrs. T. Snowden & Sons, Thirsk, Yorkshire, were awarded the first prize; in their collection were splendid Peas, Tomatoes, Broad Beans, two very fine long Cucumbers, and splendid Turnips. Mr. T. Bailey, gardener to T. T. Drake, Esq., Shardeloes, was second, and had very fine Lisbon Onions, capital Vegetable Marrows, and Cauliflowers somewhat too large, &c. Mr. W. Cragg, Timperley, was placed third, and in his collection were truly splendid Lisbon Onions. There were twelve competitors in all.

Class 40, was for the best eight dishes of vegetables, the prizes being offered by John Radcliffe, Esq., and Benjamin Whitworth, Esq. Mr. C. Frisby, gardener to H. Chaplin, Esq., Sleaford, obtained the first prize. His collection contained good Ne Plus Ultra Peas, Carrots, Walcheren Cauliflowers, Potatoes, &c. The second prize went to Mr. J. Smith, gardener, Hallcar, Altrincham, in whose collection were good Myatt's Prolific Potatoes, Finland Yellow Turnips, Celery, French Early Horn Carrots, &c. Mr. W. Dean, Sale Moor, was placed third.

In Class 41, six dishes of vegetables, the prizes offered by the Proprietors of the *Manchester Courier*, Henry Stubbs, Esq., and Benjamin Whitworth, Esq., there was a very spirited competition between twenty-three exhibitors. The first prize was awarded to Mr. Frisby, who staged a very fine lot; the second to Mr. J. Smith, Altrincham; the third to Mr. J. Pottle, gardener to B. D. Colvin, Esq., Bealing's Grove, Woodbridge, Suffolk.

In Class 42, four dishes of vegetables, prizes offered by James Carlton, Esq., and Hugh Birley, Esq., M.P., the first prize was awarded to Messrs. Snowden & Sons, Thirsk, Yorkshire; the second to Mr. W. Brownhill, market gardener, Sale, Cheshire, both of whom exhibited excellent lots.

Cottagers' Classes.—In these there were some very meritorious exhibitions. It was pleasing also to notice the immense interest taken by cottagers in this contest, and to hear the animated discussions on the justice of the various awards, and the merits of the various articles. Of the flowers and fruit exhibited, less can be said than on the vegetables, which were much the largest in quantity and the richest in quality. The window plants comprised the usual assortment of leggy Pelargoniums, with here and there a flower. The most meritorious plant was that of a Lilium auratum, well flowered, to which we should have given the first prize. Stocks were well shown by Mr. W. Clark, but these are true cottagers' plants. There was a good competition for the prize for herbs, in which Mr. H. Biddles, Loughborough, was successful. Gooseberries were not so well represented as might have been expected of Lancashire, and few of them were ripe, the season being too late for that fruit. Very excellent collections of vegetables were staged by Mr. W. Renshaw and Mr. W. Clark, who obtained the first and second prizes respectively. Mr. Renshaw's Potatoes and Turnips; Mr. Clark's Onions; and Mr. Biddles's Peas, Beans, &c., were such as would do credit to the best cultivator, and deserve all our praise. This part of the Exhibition in the provinces we are glad to see, but we hope to see it still more encouraged.

Horticultural Implements and Structures.—In this department the Manchester Show fell below its predecessors at Leicester and Bury, both in variety and number. The exhibitors here had the disadvantage of being placed in the lefthand corner, where few people cared to stroll, so that much of merit was on this account unseen by the great majority of the visitors. This was much to be regretted, as many of the exhibitors must have been at considerable expense in bringing to the Show the articles exhibited, and some of these were of sterling merit.

We must first notice the very splendid skeleton span-roofed orchard house, 80 feet in length, exhibited by Mr. Foster, of Beeston, Nottingham. It might be called a model of what an orchard house should be, for its elegance, lightness, and simplicity of construction, and its easy and perfect mode of ventilation; the latter being effected by a connecting longitudinal rod worked by a simple set of cogwheels, by which a house 100 feet in length is easily ventilated by one's finger. This house is very similar to those erected in Mr. Pearson's nursery at Chilwell, which have given so much satisfaction, and are so justly admired. Mr. Foster also showed models of his new patent boiler, which was lately recommended highly by Mr. Pearson in these columns, and which we believe ourselves to be admirably constructed and extremely efficient.

Messrs. Messenger, of Loughborough, exhibited several examples of hothouses, many of them exceedingly well adapted for their intended purpose, all in that light and graceful style peculiar to Messrs. Messenger. In one small house, a very excellent system of applying bottom heat worthy of especial notice was shown. Messrs. T. H. P. Dennis & Co., Chelmsford, had several forms of hothouses, and a number of their large and powerful boilers. Messrs. Cranston exhibited their new patent boiler, which is of rather a novel construction. Mr. Grimshaw, Manchester, had on view specimens of a double saddle-back boiler.

Messrs. Ormson, of Chelsea, exhibited examples of several new patent economic boilers. One is called Ormson's patent concentric saddle boiler, the name of which partly explains its peculiarity of construction, it being a sort of two half-circular saddles. It is in our opinion a very excellent and powerful form. Ormson's patent convoluted boiler is a square saddle-back, with the upright sides of the interior convoluted so much as nearly to close over the fire. We think in this that the action of the fire will not have the effect intended. Ormson's patent tubular boiler is a form of the square saddle-back, having a number of tubes crossing over the top of the fire, thus making it a saddle-tubular. We approve of this form. It is a pity, however, we think, that a great firm like this should not confine themselves to one approved form, instead of every season introducing something novel which is going to surpass all others, but which in another season is discarded for again another. We do not think that the boilers of to-day are in the least more powerful or economical than they were years ago, notwithstanding their multitudinous changes of form and fancy styles. Messrs. Ormson exhibited several splendid drawings of hothouses and conservatories on a large and magnificent scale; also a design for the laying-out of a nobleman's or gentleman's kitchen garden of two acres, with a gardener's house, rooms, offices, &c., all very complete, and in excellent taste.

Messrs. Weeks & Co. exhibited their patent tubular boiler, &c., and there are few to surpass it. Specimens of flower pots were exhibited by Mr. R. Saukey, Bulwell Pottery; and Messrs. W. Tickle and Son, fire-clay manufacturer, Maryport, had on view examples of rustic work in the form of seats, flower stands, &c.

Mr. W. Rendle exhibited examples of his new patent plant-protectors, which for amateurs may be desirable enough in the way of protecting small plants. There is much ingenuity displayed in their construction, yet they are very simple, cheap, and easily adjusted.

Mr. W. S. Dobson, 19, St. James Street, Piccadilly, exhibited a splendid collection of dinner-table decorations, deserving of high praise; and Messrs. Green exhibited several examples of their improved lawn mowers, garden seats, and rollers, as likewise did Messrs. Ransome & Sims, of Ipswich; and a number of seats, flower stands, baskets, &c., in wirework, were also exhibited by Messrs. Holliday, wire-workers, London.

Floral Committee. *July 20th.*—Rev. J. Dix in the chair. Mr. W. E. Dixon was awarded a special certificate for a very fine mass of Anæctochilus Lowii; the cultivation of this was considered so very superior that a medal was also recommended. Messrs. Bell & Thorpe received a special certificate for twelve Coleuses. Mrs. E. Cole & Son exhibited a very fine well-grown plant of Ixora Colei with white flowers; a special certificate was awarded, and a medal recommended. Mr. Williams, Holloway, sent a new and distinct Todea named pellucida intermedia; a first-class certificate was awarded. Cibotium Schiedei forcans and Cordyline indivisa latifolia also received first-class certificates. These were three of the finest specimens Mr. Williams has ever exhibited. Mr. Perry received first-class certificates for two seedling Verbenas, Butterfly and Rising Sun. There were several others of merit in this collection, but not in condition. Messrs. Barron and Son, Borrowash, exhibited Abies Douglasii acutifolia, a seedling, to which a first-class certificate was awarded for its distinct character. Mr. Turner, Slough, brought a magnificent collection of Carnations and Picotees, some of the finest flowers ever seen, and which must have astonished our northern friends—among them two seedling Picotees of great merit, Miss Turner, a lovely scarlet-edged flower, and Admiration, a light purple heavy-edged. The last is one of the finest varieties ever exhibited; a first-class certificate was awarded to each.

Messrs. Stansfield & Son, Todmorden, received first-class certificates for the following Ferns—Polystichum Stansfieldii; Blechnum Spicant lancifolium anomalum, and projectum forcans; Lastrea montana crispa; Athyrium Filix-fœmina Stansfieldii; also a second-class certificate for Athyrium F.f. Staleyi. J. E. Mapplebeck, Esq., was awarded first-class certificates for the following Ferns—viz., Asplenium marinum ramosum Claphami; Athyrium F.f. amœnum, Craigii, enlophos, furcillans, Mapplebeckii; Polypodium vulgare semilacerum robustum; Scolopendrium vulgare hemionitoides, crispum latum multifidum, and semipinnatum; second-class certificates for Scolopendrium vulgare Gloveri, spirale nanum, and perafero-cornutum; Polypodium vulgare kraspedomenon, and Lastrea Filix-mas foliosa. E. J. Lowe, Esq., exhibited a large number of seedling Ferns, and received first-class certificates for the following—viz., Scolopendrium Victoriæ, cuticulare, rugosum Bellairsiæ, tridentiferum optandum, poluklenon, thu-

sanasson, gloriosum, marginato-undulatum, and decorum; Polystichum angulare lineare laxum, coronare, oxyphyllum Elworthii; Athyrium F.f. Fraseri, amœnum, Hookeri, and Edwardsii; Polypodium caudatum; Asplenium marinum capitatum and imbricatum.

The prizes were distributed on the 21st inst. by the Mayor of Manchester, in the unavoidable absence of Prince Teck. On the same day the Horticultural Congress commenced, the Duke of Buccleuch, President of the Society, taking the chair. The first paper read was that of Mr. Cramb, entitled "What soil is best suited for the production of Grapes?" This and other papers we shall publish.

The following statement shows the financial result of the Show to have been highly satisfactory. The sums received were:—

July 19th, Five-shilling day	£99	0	0
,, 20th, ,, ,, ...	£210	5	0
,, 21st, Half-crown day	£539	1	10
,, 22nd, Shilling day	£352	11	8
,, 23rd, ,, ...	£286	17	0
,, 24th, Sixpenny day	£128	0	0
	£1645	15	6

In addition to the above amount, the sum of £112 was received for tickets sold previous to the opening of the Show, and £100 from the refreshment contractors, making the total receipts £1857 15*s.* 6*d.*

ENTOMOLOGICAL SOCIETY'S MEETING.

The last meeting of the season was held at Burlington House on the 5th instant, Mr. F. Smith, Vice-President, in the chair. Amongst the new books presented since the last meeting to the Society were the publications of the Royal, Linnean, and Stettin Societies, the fourth volume of Harold & Gemminger's Catalogue of Coleoptera, and the first part of a new periodical work on exotic Butterflies, printed in chromolithography by Mr. Butler. Amongst the visitors at the meeting were Professor Schiodte, of Copenhagen, and Drs. Kaaf, of Darmstadt, and Candeze, of Liege. Mr. J. J. Weir exhibited a Tick of gigantic size, belonging to the genus Ixodes, found on a live Greek tortoise. The Chairman mentioned an instance in which he had been attacked by one of these insects. Mr. Barclay called the attention of the meeting to the injuries committed on the sugar canes in the island of Mauritius, by numbers of insects of the genus Coccus, known by the inhabitants under the name of the "Pou blanc." The Chairman communicated a drawing by Mr. Ford of the beautiful luminous larva which he had exhibited at the last meeting, and called attention to Mr. Andrew Murray's memoir on luminous larvæ, recently published in the "Proceedings" of the Linnean Society. He also exhibited living specimens of Pissodes notatus from Bournemouth, and of the field Cricket, Achatu campestris, from Farnham.

"Notes on the Entomology of Adelaide," by Mr. C. A. Wilson. These notes were of a desultory character, but amongst them the author mentioned the discovery of the genus Xenos in South Australia, parasitic in the bodies of wasps of the genus Paragia. Mr. Edwin Brown sent some "Observations on Australian Cicindelidæ," with description of a beautiful new species captured by Mr. Du Boulay, Tetracha Adonis.

The Honourable T. De Grey exhibited and made some observations on Cosmopteryx Aurichalcea, and on a dark variety of Carpocapsa Juliana; and Mr. Wakefield made some remarks on the insects of New Zealand, which he affirmed to be very few in number, and by no means striking in their appearance. He had only obtained fourteen species of Butterflies, and 250 kinds of Moths, amongst which the common English Clear-wing Trochilium tipuliforme had been introduced from this country with Currant trees. Mr. S. Stevens stated that the fine collection of insects of the late Mr. Turner, M.P. for Manchester, would be sold by auction in the course of the autumn.

FINDERNE FLOWERS.

The Findernes were Lancastrians, so when, during the War of the Roses, the Yorkists were ascendant, the ruin of the Findernes was consummated, and Edward IV., in 1473, granted "all the manors and hereditaments within the kingdom of England lately belonging to William Finderne," to Robert Radecliffe; no wonder the Radclyffes still delight in Roses. Burke, in his "Vicissitudes of Families," relates as follows:—

"The hamlet of Finderne, in the parish of Mickleover, about four miles from Derby, was, for nine generations, the chief residence of a family who derived their name from the place of their patrimony. From the time of Edward I. to those of Henry VIII., when the male line became extinct, and the estate passed, by the marriage of the heiress, to the Harpurs, the house of Finderne was one of the most distinguished in Derbyshire. Members of it had won their spurs in the Crusades, and at Cressy, and at Agincourt. The sons were brave and the daughters fair: one, alas! was frail as well as fair, and the heaviest blow that ever fell on the time-honoured race was when Catherine Finderne, about the middle of the fifteenth century, consented to be the mistress of Henry, Lord Grey of Codnor. In the remarkable will of that remarkable nobleman, who, in 1463, obtained a licence from the king for the transmutation of metals, provision is made for his illegitimate issue, by Catherine, in terms which were, no doubt, deemed unexceptionable in those days, but which would be deemed highly offensive in our own. The territorial possessions of the Findernes were large: the Findernes were High Sheriffs, occasionally Rangers of Needwood Forest, and Custodians of Tutbury Castle, and they matched with many of the best families. Finderne, originally erected *tempore* Edward I., and restored and enlarged at different periods, was in 1560 one of the quaintest and largest mansions in the midlands. The present church, then the family chapel, had rows of monumental brasses and altar-tombs, all memorials of the Findernes. In 1850, a pedigree research caused me to pay a visit to the village. I sought for the ancient Hall. Not a stone remained to tell where it had stood! I entered the church—not a single record of a Finderne was there! I accosted a villager, hoping to glean some stray traditions of the Findernes, 'Findernes!' said he, 'we have no Findernes here, but we have something that once belonged to them; we have Findernes' flowers.' 'Show me them,' I replied; and the old man led me into a field which still retained faint traces of terraces and foundations. 'There,' said he, pointing to a bank of 'garden flowers grown wild,' 'there are the Findernes' flowers, brought by Sir Geoffrey from the Holy Land, and do what we will, they will never die!'

"Poetry mingles more with our daily life than we are apt to acknowledge; and even to an antiquary like myself, the old man's prose and the subject of it were the very essence of poetry.

"For more than three hundred years the Findernes have been extinct, the mansion they had dwelt in had crumbled into dust, the brass and marble intended to perpetuate the race had passed away, and a little tiny flower had for ages preserved a name and a memory, which the elaborate works of man's hand had failed to rescue from oblivion. The moral of the incident is as beautiful as the poetry. We often talk of 'the language of flowers,' but of the eloquence of flowers we never had such a striking example as that presented in these flowers of Finderne:—

'Time, Time, his withering hand hath laid
On battlement and tower,
And where rich banners were displayed,
Now only waves a flower.'"

BRITISH FERNS.

Having lately paid a visit to Messrs. Ivery's well-known establishment at Dorking, and enjoyed the opportunity of examining their extensive collection, perhaps a few notes of some of the more recent introductions might not be uninteresting. Talk of florists' flowers, why we shall soon have such a variety of our native Ferns as will put into the shade any collection of florists' flowers that we have, and with differences so minute, that it would require one to be thoroughly well acquainted with them to know their names. I am not about to give a mere catalogue of all that are distinct and good, but only to notice such as are not so well known, but which are deserving a place in any collection.

Let me take the Lady Ferns first as in duty bound, and first of all Athyrium Filix-fœmina Girdlestoneii, a lovely variety discovered by the Rev. Mr. Girdlestone, and named after him. Nothing can be more delicately lovely than the fronds of this exquisite Fern. The leafy part of the pinnules is wanting, only the veinlets are present, giving it quite a skeletonised appearance; and when the fructification appears it adds still more to its singular beauty. Athyrium Filix-fœmina Frisellæ nanum.—All Fern-lovers are acquainted with the very singular variety called Frisellæ, so very unlike a Lady Fern. This is a very remarkable variety of Frisellæ, very dwarf, the fronds not being more than a foot in length, and, instead of drooping over as in the older variety, are stiff and blunt-ended. Athyrium F.f. formoso-cristatum is one of the most elegant of many crested forms of Lady Fern, and not only curious but really handsome. Athyrium F.f. lanceolatum is very delicately cut in the fronds and pinnæ, and distinct in character, the slender pointed form of the former marking it as distinct. Athyrium F.f. Iveryanum, a remarkable variety, apparently having an analogy with Frisellæ and Fieldiæ, as it has the short stiff fronds that mark Frisellæ nanum, but with the peculiar forked

form of the pinnæ of Fieldiæ. It is dwarf in habit, and very stiff. Athyrium F.f. plumosum (Axminster var.), is one of the most lovely, if not positively the most so, of all the Lady Ferns. It differs from the ordinary variety of plumosum in being still more feathery and light, and when seen in large plants, as I saw it at Mr. Ivery's, is surpassingly lovely.

Besides these there were, of newer kinds, Bellairsiæ, Clarkiæ, eroso-cristatum, scopiæforme, curtum, and grandiceps pumilum.

The Male Fern has produced varieties not quite as numerous but as fine, though not, perhaps, so delicately beautiful as the Lady Fern. Among them I noticed Lastrea Filix-mas Ingramii, a very beautiful form, the fronds sometimes being 3 and 4 feet in length, while the narrow deeply-cut pinnules gave it a very distinct appearance. Lastrea F.mas cristata angustata, a very beautiful form of the old cristata, itself one of the very finest Ferns we have. The fronds are narrow, the crest at the end of the fronds being very close and crispy, while the pinnæ are also shut and closely tufted. Lastrea F.mas crispa, one of those varieties that makes us wonder if it can really belong to the same family as the stately Male Fern of our hedges, the fronds being only about 9 inches high, the pinnæ being closely placed together and deeply imbricated, so that it has altogether a most crisp appearance. Then there are Lastrea Filix-mas cristata Iveryana, cristata crispa, foliosa, &c.

But I question whether for real beauty any of our native Ferns can vie with the varieties of Polystichum, especially those of the proliferum section. What more beautiful than a well-grown plant of proliferum Wollastoni, of which I have a plant now before me with fronds 2 and 3 feet in length? while their being, if not altogether, at any rate very nearly evergreen, is a great recommendation.

Of the varieties of Polystichum angulare there are Bayliæ; the fronds of this variety are of a very deep green, the pinnules very sharp and pointed and closely set on, so as to form a very attractive variety. Cristatum.—In this the point of each frond terminates in a thick crispy tuft, and corresponds altogether very much to the cristata form of Lastrea F. mas. Oxyphyllum.—The fronds are very scaly, and in Jackson's variety even more so. It is a very beautiful variety, the stalks being slender and graceful. Plumosum.—A beautiful feathery form of Polystichum, analogous to the plumose variety of Lady Fern, and, like it, exceedingly graceful and beautiful. Proliferum Holeanum.—A most lovely Fern, the pinnules separated somewhat widely, very pointed. Rotundatum.—A very remarkable variety; the fronds being of a very dark green colour, and the outline of the pinnæ is so far rounded as to give it a very distinct appearance. Lineare.—Dark green fronds, very spare; indeed it is very analogous in the Polystichums to Girdlestonei in the Athyriums. But perhaps the most beautiful of all the new Polystichums is the very fine Polystichum angulare Pateyi, discovered in Dorsetshire by Mr. Patey, after whom it is called. The colour of the green is light. The plant is very dense, owing to the overlapping of the pinnæ; the pinnules being deeply incised. It is a very rare variety, there being at present only five plants of it in existence, and these were obtained by cutting up the old stool. Mr. Ivery has not succeeded in inducing it to bear spores. If it do not do so, some time must elapse before it can be generally grown, but it is certainly one of the grandest Ferns we have.

Besides these there are many other beautiful forms, such as laciniatum, laciniato-truncatum, Kitsoniæ, tenue, Wakeleyanum, and Stansfieldii.

Scolopendriums are as numerous as any; but with the exception of a few forms, such as crispum, marginatum, and its varieties, I do not care particularly about them. Of the Polypodiums, ramosum, pulcherrimum, acrocladon, cristatum, bifido-lobatum; of Asplenums, Harovii and incisum; and of Blechnum, concinnum, heterophyllum, and imbricatum, are distinct and curiously beautiful; and it is impossible to pass through this nursery, see pit after pit filled with these beautiful plants in all stages of growth, from the tiniest little seedlings to the large and magnificent plants we see at our metropolitan shows whenever Messrs. Ivery exhibit, without being struck with their immense variety, and with wonder that not more of these lovely plants are grown. We know that the demand for them is great. Mr. Ivery told me of his having sent them by the ten weight; but they are so readily grown, that, while each place has its fernery, it is a pity that some of these rarer and most beautiful forms do not find a place in it. Sitting as I am this moment, in the cool shade on this broiling hot day, and looking on many of those which I have alluded to above, they do indeed seem to me most lovely and deserving of the enthusiastic praise which a real lover of Ferns bestows on them.—D., *Deal*.

WINE PRESS.

On reading the instructions on "Wine Manufacture" by "Upwards and Onwards," vol. xvi, page 409, he says, "If there were, in addition, a large pestle and mortar." About ten years back I made a pair of zinc rollers 4¾ inches in diameter, 6 inches long, and fluted the whole length. (*fig.* 1); these I mounted in a wood frame (*fig.* 2); to run one in the other, and turned by a crank handle. They are moveable—open or close for Rhubarb, Gooseberries, or Currants. There is a hopper to fit on the top for the Gooseberries and Currants. I also made a small screw press (*fig.* 3). With the rollers we crush in one hour all the fruit we used to do in three-quarters of a day. The press takes about the same time as by hand, or only a little less time, but we obtain considerably more wine from the same weight of fruit. There are several wine-makers in this town; I lend the rollers and press to them, and for the use some send me a quart bottle of their wine at the time of bottling. If these sketches should be of any service to "Upwards and Onwards," or should be like further information how to make apparatus like them—I made my own patterns and castings, and fitted them up—I should be most happy to give it.—W. Stuttle, *Thornbury*.

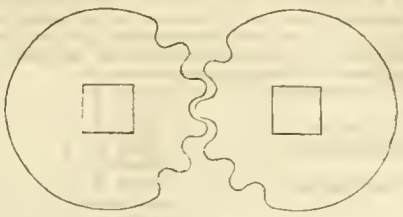

Fig. 1.—Zinc rollers, full size, 6 inches long; a portion of the teeth only shown.

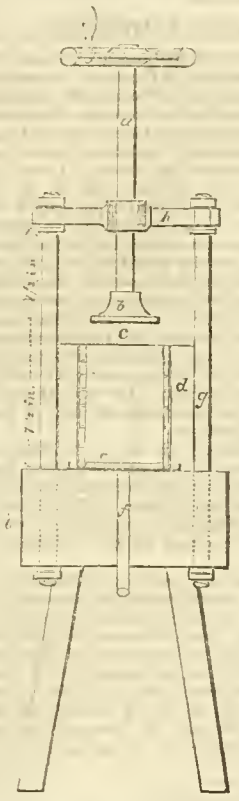

Fig. 3.—*a*, 1-inch iron screw, 16 inches long, worked by a hand wheel; *b*, zinc plate, 4¾ square; *c*, zinc box full of holes; *d*, wood box or casing; *e*, zinc plate full of holes; *f*, pipe to convey the juice away, and provided with a tin top; *g*, ¾ iron rods; *h*, cross bar with screw thread for the pin *a*; *i*, wood block 13 inches square, 6 inches thick. The wood legs are 2 inches in diameter, turned, and 14 inches long.

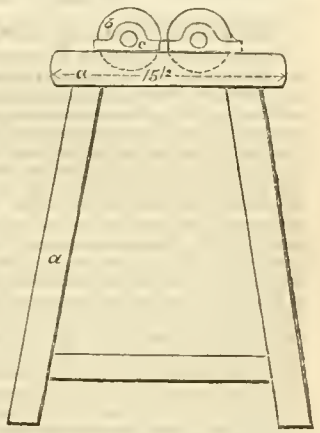

Fig. 2.—*a*, Wood frame, 2 feet high, 2½ inches deep, 1¾ inch thick; *b*, zinc rollers, 4¾ inches in diameter, 6 inches long; *c*, iron pedestals, moveable. The rollers are worked with a crank handle, 8½ inch centre.

THE SMALL TELTOW TURNIP.

Those of your readers who have travelled on the Continent, and have been while there a little gustatory, may have observed very frequently the pleasant smell arising from, and the flavour of, various soups. Both, for the most part, are given by the above kind of Turnip, which is, when served up like our common Turnips, very pungent, and to us English not palatable,

but to soups and stews it gives an exquisite flavour. It is like a Carrot in shape, and about the size of a moderate one. Its seed is remarkably small, and requires to be sown on fine friable or sandy soil. I sow my crop in the middle of June, but it may be sown in July. I do not observe this kind of Turnip in our English seed lists. It should be in every garden. —T. R.

NEW BOOK.

A History of Ornamental-foliaged Pelargoniums, with Practical Hints for their Production, Propagation, and Cultivation. By Peter Grieve. Second edition, enlarged. W. Blackwood and Sons, Edinburgh and London.

A striped-leaved Pelargonium, probably the same as Miller's Variegated, was introduced from France in the year 1724, but zone-leaved species had been cultivated in this country some years previously. Pelargonium zonale was in the garden of the Duchess of Beaufort in 1704, so was P. peltatum, the leaves of which have a circular purple blotch in the centre. A third African species is described by Ray as having silvered leaves, a fourth with a purple zone, and a fifth with golden foliage. He also mentions the Ivy-leaved as being introduced from the Cape of Good Hope, and flourishing in the Duchess of Beaufort's garden in 1701. We merely mention these as evidence that ornamental-foliaged Pelargoniums were known and prized much earlier than is usually supposed.

We are pleased to welcome this second edition of Mr. Grieve's book. It is full of instruction relative to its subject; and as evidence of its practical character, we will make a short extract from his directions how to raise new varieties.

"Let a dozen or more of the finest Green Zonal varieties be obtained, and also a like or a smaller number of the finest Gold and Silver Variegated Zonal sorts that are to be had. I will suppose them to have been all struck from cuttings during the months of August or September, and to be growing in pots, say, about 4 inches in diameter. They must be wintered in an ordinary greenhouse, giving the variegated varieties the advantage of a shelf near to the glass; and the temperature of the house must not be allowed to fall much below 45°, as a minimum, admitting air, however, freely when the weather will permit. Under this treatment the plants, both green and variegated, will continue to progress slowly during the winter months, and will require to be shifted into their flowering pots about the first week in February. The size of the pots for the Green Zonal varieties should not exceed 6 inches in diameter, and the same, or perhaps a size less, will be suitable for the variegated sorts; but great care must be taken that the pots for the latter sorts are well drained. They will all grow, and produce seed freely, in almost any moderately rich soil, avoiding peat, however; but I would recommend a soil composed principally of rotted turf, with the addition of a portion of leaf mould or well-rotted manure. It is better to avoid a very rich soil, as great luxuriance is not desirable.

"After they have been repotted, let them be well watered with a fine rose watering-pot, and replaced as before recommended, giving the variegated sorts, as being the most delicate, every possible advantage in regard to position, and keeping the house rather close and moist for a week or two, after which abundance of air may be given when the weather is favourable; but at the same time, so as to avoid anything like cold draughts. Let the plants have water only when they really require it, and let the pots be frequently turned round, so that all parts of the plant may have equally the advantage of being exposed to the sun and light.

"Early in the month of May most of the plants will be in flower, the variegated varieties as well as the green-leaved sorts. They may now be placed, in order to be operated upon, in some light and convenient position, such as the front of a greenhouse, or other light structure. Continue to give plenty of top air; but it will be advisable to keep the front lights closed, to avoid draughts, and also, to some extent, to exclude insects. A day temperature of not less than 70° will be found necessary, or, at least, most conducive to sexual development; and at this season (June—July), this temperature can generally be maintained without the aid of fire heat, while, by closing the house somewhat early, in accordance with the state of the weather, the night temperature will seldom fall lower than 50°.

"The time may now be said to have arrived when the intending cross-breeder is called upon to exercise his judgment in the selection of the parents of his future seedlings; and this is perhaps the most important part of the whole business.

"I have before observed that although the varieties of Variegated Zonal Pelargoniums already in the country are exceedingly numerous, yet comparatively few of them will, I suspect, be found to be eligible as bedding plants, on account of their delicacy of constitution or deficiency of vital or growing power. Perhaps the principal cause of this, in addition to the admitted debilitating influence of variegation itself, is the practice of selecting variegated varieties for the seed-bearing parent, using the green-leaved varieties only as pollen parents. Without wishing altogether to condemn this practice, I would, nevertheless, in most instances, recommend a contrary procedure—viz., to make the green-leaved variety the seed-bearing parent, and to use the pollen of the variegated sorts, my conviction being that in the vegetable as in the animal kingdom, the male is generally the most active in stamping the leading characteristics or peculiarities of its nature upon the progeny, while the constitution of the female is generally, to some extent, inherited by the offspring."

LAXTON'S SUPREME PEA.

Though the varieties of Peas are numerous, yet many are so little distinct that I am convinced several names are often attached to a variety. Probably a selection of eight good kinds is sufficient to ensure successional crops throughout the season. Laxton's Supreme should not be omitted, for I am of opinion that its qualities are all that can be desired. I have now several rows in full bearing, and nothing, as a Pea, can possibly be stronger, healthier, and more handsome. These were sown in trenches, as prepared for Celery, with an ample supply of manure from an old Melon bed, only covering the manure with 4 inches of soil to sow the seeds in. I presume the plants have overgrown themselves this season, measuring 6 feet in height. They bear in profusion large fine pods containing from seven to nine Peas in a pod, these being of a dark green colour, and of excellent flavour.—Henry C. Ogle, *Welwyn*.

TREES INJURED BY THE WEATHER—POTATOES.

Mr. Leach, Lord Portman's gardener, called to-day (July 20th), to see the Roses, Strawberries, fruit trees, and Potatoes. He gives much the same account as Mr. Robson (page 42). He says the magnificent Plane trees at Bryanstone are much injured, and have hardly a leaf left. Two fine Beech trees have died, and the Beeches generally, besides other trees, are in a sad plight. He has raised a splendid second-early Potato, called the Bryanstone Kidney, which he is going to give me. I showed him the American Potatoes; he admired their haulm and foliage. I also dug him up a tuber each of the Early Rose, Brezee's No. 4, and Climax. We thought Climax the best-looking. When it came it was the worst-looking of all the Americans. I tasted the Early Rose the same day, and Brezee's No. 4. They are exceedingly white in flesh, and I think will be good Potatoes, being very delicate in flavour, far more so than the English Potatoes, but they are not so rich as our Kidney Potatoes. Being hardly ripe, I cannot yet tell their merits.—W. F. Radclyffe.

CUCUMBER CULTURE.—No. 7.

The seed to raise plants for winter fruiting ought to be sown in the first week in September. The plants from this sowing will be strong and in full bearing by January or early in February, but a little fruit may be obtained long before this. The plants may be raised on a dung bothed in a house having the proper temperature, or in the house in which they are to be grown. As the general treatment has been described in previous articles, it is unnecessary to repeat it here, but there are some points in which it differs. The plants must be potted singlyin 3-inch pots when showing their rough leaves, and when the pots are full of roots shift the plants into 6-inch pots, which are sufficiently large till the time for planting-out. This should be done before the roots become very closely matted round the sides. If the plants cannot be turned out, they should be shifted into larger-sized pots as soon as their present ones become full of roots, but the sooner they are planted-out after they begin to grow freely the better.

It is a practice with many, indeed most, cultivators not to stop the plants until the original shoot or runner is long enough to reach the trellis. I think this gives a very slender weak stem, and as a preventive I take out the point of the shoot at the second joint, or immediately above the first rough leaf. This gives a strong shoot, and if more shoots show, they are picked out with the point of a sharp knife when little larger than a pin's head. A stick long enough to reach from the surface of the soil in the pot to the trellis is placed to each plant, and to this the runner is lightly tied, and not again stopped until it has grown two joints beyond the trellis; its point is then taken out. The shoots showing in the joints of the future stem are taken out with the point of a knife as soon as they appear, but allowing the leaves to remain for some time

longer, until there are a dozen or more good leaves on the trellis to elaborate the sap; then the leaves on the stem may be taken off. The shoots coming from the three highest joints must not be taken out, but left to produce vines or runners for furnishing the trellis.

When the plants are large enough to plant-out, the bed must be prepared. It may be made the full width at once, but I think the plants do best when only part of the width is formed at first; but the drainage, of course, is put in to the whole width, and covered with a layer of turf, or the rougher portions of the compost, not more than 2 or 3 inches thick. Along the front, next the wall dividing the bed or border from the hot-water pipes, soil may be placed, making it 15 inches deep, for it will settle down to a foot or less, and if it be 18 inches wide at top, with a base nearly twice that width, it will be sufficient at first. The plants ought not to be turned out in the bed until the soil be quite warmed through, and in temperature from 70° to 75°, though 85° will not injure the roots. The temperature of the soil ought to be determined by a ground thermometer plunged 1 foot deep, or not less than 6 inches.

The soil most suitable for winter is formed of two parts turfy loam, taken off 2 or 3 inches deep from the surface of a pasture where the soil is neither a very light nor yet heavy yellow or hazel loam, and thrown up in narrow ridges alternately with fresh horse droppings. It should be allowed to remain thus for six months, and when required for use it may be chopped-up, but not sifted. To the preceding add one part sandy turfy peat, chopping it up rather small, and mixing it well with the loam, and a half a part of white or river sand, well mixing the whole.

The plants should be placed about 9 inches from the edge of the bed which is next the pipes, or the front of the house or pit, and 3 feet apart, taking care to have the soil moist, so that only a gentle watering will be necessary at planting to settle the soil about the roots. In planting, do not put in the plants deeper than where the seed leaves were, nor make the soil very firm, keeping between the two extremes.

The soil should never be allowed to become so dry as to cause the foliage to flag, still it should be rather dry before water is given. Avoid over-watering, for if the soil ever become sour and saturated the roots will perish, or become inert, and the leaves flag when exposed to powerful sun. All watering up to February should be with rain water only, and at no less a temperature than 75°, nor exceeding 80°. In February liquid manure may be given once or twice a-week, and always at the above temperature, taking care not to apply the liquid too strong.

The atmospheric moisture required may be supplied by sprinkling the paths, walls, and other surfaces between 8 and 9 A.M., at noon, and at 3 or 4 P.M. This should be done from the time of planting up to March, except in very cold weather, when the noon syringing may be dispensed with, and in very dull, moist weather the morning syringing will generally be sufficient. On very fine days the plants may be lightly syringed overhead early in the afternoon, when the house is closed for the day. After February the atmosphere should be kept very moist, and the plants sprinkled or syringed overhead in the afternoon. It must not, however, be done with a close atmosphere; abundance of moisture must be accompanied with an abundance of air. The paths and other surfaces ought to be kept moist—more so in fine than in dull weather, at least the sprinklings will need to be more frequently repeated.

Ventilation must be very carefully managed, especially during sharp frosts. A piece of wool netting should be nailed over the openings, and care taken not to admit air in such quantities as to suddenly cool or dry the atmosphere, but admit it in moderation, and never with the view of lowering the temperature. Air should be given before the thermometer rises too high, and reduced before it falls too low. A little air ought to be left on night as well as day, and the lights may be opened when the temperature reaches 75°, if it is likely that sun heat will raise it to 85° or more, and the house may be closed at 80°, the ventilation being then reduced to its minimum. The true principle of giving air is to admit it early, and progressively with the increase of temperature, to secure a thorough change of air with plenty of sun heat, and to close the house with as much sun heat as possible, or consistent with the well-being of the plants. From sun heat 90° may be permitted, air being given when the thermometer rises to 75° if the temperature be likely to exceed 80°. To allow the temperature to rise above 85°, and then reduce it to 80° again by air-giving, would be wrong. Usually the more air plants have by night as well as by day, the better they thrive. The temperature by day should be from 70° to 75° without sun, and from 80° to 90° with sun and air; by night about 65°.

The evaporation troughs, which are indispensable, may be kept full of water until February, but they may then be filled with a solution of 1 lb. guano in twenty gallons of water. If to this is added one peck of soot, one peck of sheep's droppings, and ten gallons more water, we obtain an excellent liquid for watering the paths every evening when the house is closed; and upon a further addition of ten gallons of water, a first-rate liquid manure is formed, suitable for watering the plants once or twice a-week, but not till February arrives. The benefit derived from merely wetting the floors or walls is, that along with the moisture, ammonia is supplied to the atmosphere, and the plants are kept healthier and more free from insects. The temperature of the liquid used for damping the floors or walls should never be lower than the present temperature of the house, but, if anything, 5° higher.

If the border is not made to the full width at the time of planting, it should be extended as the roots of the plants begin to push through that portion first formed. The compost used for this purpose should have been kept for some time in the house before using it. The width of the border may be increased as the roots extend, and there is one advantage in knowing that the soil has not become sour or sodden by watering before it is occupied by the roots, and that these, in consequence of the gradual addition, must have pervaded every part. If the plants thrive, the full width of border should be attained in six weeks. If the surface of the border or bed become close, and the plants begin to lose vigour, they may in March or April, and every following month, have the surface soil removed, taking it clear away as far as the roots, and replacing it with a layer, varying from 1 inch to 1½ inch in thickness, of turf which has been kept in alternate layers with horse droppings for six months, chopping it up previous to use. The roots near the stem, and the adventitious roots springing from it, should be encouraged by covering them with the compost, so as to attract them into parts more remote from the stem.

Having, as above advised, stopped the leading shoot when two joints up the trellis, two or three shoots will start from the bases of the leaves. As only two are required, select the best and train them straight up the roof, keeping them 18 inches apart. If there be no signs of their fruiting, stop them at the sixth leaf; this will produce laterals, one of which must be trained as a continuation of the main shoot, the other treated as fruit bearers, and trained about 9 inches apart, so as not to be overcrowded. The leaders, as well as the side shoots, will produce fruit, and should all be stopped one joint beyond the fruit; but the side shoots, if a shoot is pushing from the same joint as the fruit, ought to be shortened to that, and it will most likely show fruit at the second or third joint. It must then have its point pinched out one joint beyond the fruit—at the fruit if there is a shoot coming from the same joint. The leaders must be preserved, stopping them, if not showing fruit, when the sixth leaf is formed, so as to encourage laterals. When the principal shoots reach the top of the trellis they should be kept at one joint beyond the fruit, or to the fruit joint if it have a shoot, and this until they become weak from bearing, in which case the old principal shoots must be replaced by fresh ones from the bottom of the trellis, always keeping the bottom of it well covered with young shoots for this purpose.

Thin-out the weak shoots soon, cutting away the unfruitful laterals and those that have become barren, so that those left may be trained moderately thinly and regularly. Clearing away a lot of entangled shoots should be avoided as much as possible, and the knife should not be used, except for cutting away weak parts, but the finger and thumb should be employed for pinching-off the points of the shoots, as the bleeding is not so severe, and no loss of leaves is occasioned.—G. ABBEY.

CUTTING DOWN YOUNG VINES TO OBTAIN TWO GROWTHS IN ONE SEASON.

IN 1865 I was anxious to prepare a quantity of extra strong young Vines in large pots, and not being very well off for a place to grow them in, they were put into a Muscat-house with a high temperature. This was after they had been shifted into 14-inch pots. Under circumstances over which, unfortunately, I could have no control, they were allowed to remain in the house till the Muscats completely covered the roof of the vinery,

and became gradually weaker and weaker from the want of light and air, so that they looked more like being sent to the rubbish-heap than ever becoming Vines that would bear a crop the following year. I, however, decided to cut them down to within a bud or two of the surface of the pot, and had them placed in a light house with a night temperature of 70°, with 15° to 20° more with sun heat by day. Water was sparingly applied, and they very soon burst their main buds, which, under ordinary circumstances, would not have moved till the following year. They came away with amazing vigour, and made magnificent Vines 10 feet long—the strongest I ever had under my care.

This season, on the 16th of March, I planted a house of Muscats, and the last week of May, after they had made fine growths 8 and 9 feet long, these were cut down as described above. They likewise soon burst their main buds, and are now twice as strong as they were when of the same length in their first growth. And where Vines planted one year are required to yield the finest possible crop the year following. I would strongly recommend this two-growths-in-one-season system as one that will produce a more vigorous Vine of a given length than if allowed to grow on at first.

All gardeners who have had the charge of Vines can scarcely fail to have observed how very strongly a Vine in a green unripened state, when growing vigorously, bursts its main buds when the laterals are closely stopped; and the same increase of dimensions takes place when a young Vine is cut down as I have described. It is necessary, however, in order to get season sufficient to ripen the second growth thoroughly, that the Vines be planted in March, and that the cultivator have a good command of heat, in the case of Muscats especially.—D. Thomson (*The Gardener.*)

NOTES AND GLEANINGS.

Mr. Ambroise Verschaffelt, of Ghent, has disposed of his horticultural establishment, including his periodical "L'Illustration Horticole," to Mr. J. Linden of Brussels. Letters to the establishment are in future to be directed to "M. P. Gloner, Director of the Establishment of A. Verschaffelt, Rue de Chanme, Ghent."

—— It is our great pleasure to record that the eminent services rendered by Mr. John Shaw, of Manchester, at the Royal Horticultural Society's Show, have been acknowledged in a way which reflects credit on the Council, they having elected Mr. Shaw a Forty-Guinea life Fellow of the Society.

—— The horticultural world will learn with great regret the decease of Mr. John Bevan Whiting, one of the best of our English gardeners, whose quiet unobtrusive manner and professional skill secured for him an amount of general esteem which it is the lot of but few men to enjoy. Mr. Whiting was, we believe, a native of Devonshire, and for some time was one of the foremen in the Horticultural Society's Garden at Chiswick; and from there he went as gardener to the Earl of Tyrconnel, at Kipling Hall, Yorkshire. It is, however, with the gardens of the Deepdene, near Dorking, that his name is more particularly connected, for there he remained till within a month before his death, a period of nearly thirty years. He was a contributor to Loudon's "Gardener's Magazine," and to the *Gardeners' Chronicle* from the commencement; he likewise furnished cultural instructions in some of Mrs. Loudon's works on gardening. He was a member of the Fruit Committee of the Royal Horticultural Society, and frequently attended and exhibited at their meetings. Mr. Whiting, who never in his later years enjoyed robust health, died on the 19th inst., at the residence of his son, near Hereford.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Clear away haulm, stumps, and the refuse of crops directly they are over, and if there is no immediate use for the ground, dig it up to remain till wanted. At this season, however, there is seldom ground to spare, for it should be remembered that the supply for much of the next winter and spring will depend on the diligence now shown in planting out as large a number as possible of those kinds of vegetables most likely to be in demand at that time. To forward this, *Potatoes* and other crops soon coming off may be interlined with any kind of *Broccolis* or *Winter Greens*; but where sufficient room cannot thus be obtained, a quantity may be planted 1 foot apart until ground is afforded them by the removal of other crops, when the whole may be again planted at proper distances, or every other row, and each alternate plant of the remainder removed to vacant ground. The above mode will answer well where ground is limited, more particularly with those kinds coming into use in spring. Pay strict attention to the requirements of growing crops.

FRUIT GARDEN.

The summer pruning and nailing-in of the present year's wood will require following up, as the late favourable weather has caused an increased growth of midsummer-wood, which may remain for a short time; and it is also probable that some of the foreright shoots which were stopped earlier may again break. When this is the case, it will be better to wait for a week or two, when the growth becomes less active, before stopping or netting-back is resorted to. Those trees which had their breastwood loosely tied-in may now have the shoots cut back to two or three eyes, beginning with the least vigorous trees first, as they will be least likely to start, and allowing the stronger kinds to remain until their growth has so far ceased as to preclude all danger of their breaking, which would prevent the formation of fruit-buds from the remaining eyes. Where time will permit, thinning the wood of this year's growth in the case of Currants, Gooseberries, and Raspberries will be found beneficial, leaving only sufficient to furnish next year's crop. A portion of the Gooseberry and Currant bushes should be matted-up, or protected in some way from the ravages of wasps and birds, for autumn use.

FLOWER GARDEN.

The flower garden will now be in its greatest beauty, and every means must be taken to keep turf, gravel, and edgings of all kinds in the neatest order, that there may be no drawback to the general appearance of the whole. Fork the ground slightly around Dahlias, and mulch the surface with very rotten manure; water plentifully every evening when the weather is dry, taking care that the laterals are well staked out, and every means taken to entrap earwigs and other injurious vermin. Look over the faded blooms of Pinks, extract the petals from the pods, for should rain set in these decayed petals will act prejudicially by retaining moisture round the lower part, causing decay and consequent destruction. We expect a capital seed season. Rooted cuttings of Pansies for making-up the autumnal beds will now be almost, if not quite ready; it will, therefore, be necessary to prepare the beds for their reception. In doing this it is absolutely necessary that wireworms should be caught, as these pernicious insects are as destructive amongst young Pansies as they are to Carnation layers; the compost should, therefore, have repeated turnings. Throw out the soil from the Tulip-bed on the paths, so that the soil may sweeten before being returned.

GREENHOUSE AND CONSERVATORY.

I have previously mentioned the advantage derived from giving plants some kind of rest after blooming, to restore their exhausted energies, and to enable them to make a vigorous start when the new growth commences. At this season, greenhouse plants which have finished blooming should have a comparatively cool temperature, which is nowhere better obtained than in a house with a north aspect. I may state further, that for growing delicate-leaved plants throughout the summer, houses having a north or north-east aspect are to be preferred, while for the purpose of retarding plants, or for preserving them in bloom, they are indispeneable. Such plants, therefore, as Epacrises, Leschenaultias, Pimeleas, Aphelexes, and others of similar habit, which have been kept for late blooming, and are now over, should be placed in a house of the above description, or in deep frames with the sashes turned towards the north, the old blooms being first picked-off; here, by gently syringing once or twice daily, the plants may remain till a new growth commences, when any pruning they may require may be given them, and they may afterwards be placed in more favourable positions for ripening their wood. Camellias, whenever the young wood shows signs of ripening, may be removed to the open air; a situation shaded from the mid-day sun, and sheltered from high winds, should be secured for them. Be careful to place them on a dry bottom to prevent the possibility of worms getting into the pots. Chinese Azaleas, which are equally forward in their growth, and have formed their next-year's flower buds, may likewise be turned out; unlike Camellias, the latter require full exposure to sun and air, and should be placed in an open

situation that their wood may become thoroughly matured; it will, however, perhaps be necessary to place them for a week or two in a partly-shaded situation to harden their foliage sufficiently to bear the full sun, or else the sudden change from a house to bright sunshine might cause their leaves to turn brown and burn. Orange trees when too full of bloom should have the flowers thinned out. They are always in request, either for drying or distilling. The young fruit, when too thickly set, should likewise have a thinning, as a few will be sufficient to remain. To produce dark glossy leaves, water with clear soot water.

STOVE.

A number of Orchids will by this time have made their growth, and may be gradually removed to a drier and cooler atmosphere. Those which continue growing must have the syringe two or three times a-day, and a humid atmosphere maintained by well watering every vacant part of the interior. At the same time, the material in which plants on blocks or suspended in baskets are growing should be frequently soaked to completely moisten it. Some young plants, which it is desirable to lose no time with, may again have a shift, if potted as above. They have had a short rest since the spring growth was completed.

COLD PITS.

The stock here will probably require re-arrangement. Any of the specimens which require more pot room should be shifted as soon as possible, taking care to have the ball moist, and keeping the atmosphere rather closer and moister by sprinkling the plants overhead for a fortnight after potting. Let the young shoots be tied before they begin to fall about, crowd, and injure each other. Cut down Pelargoniums as soon as the wood is properly hardened, and keep them very sparingly supplied with water at the roots until they start into growth, but sprinkle them frequently overhead, as it will cause them to break more strongly. Continue to pot Cinerarias as strong suckers can be obtained, placing them in a close cold frame until they become established in their pots.—W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

WITH such a week of scorching weather, and little or no signs of rains (the thundershowers having refused to come), planting was out of the question, except where abundance of water and shading was at command. Even sowing would be of little use, unless the ground had been previously moistened, or the seeds treated as stated lately for the earliest Cabbages. Made successional sowings of Cabbages, Endive, Lettuce, Turnips, and Radishes. Ere long we shall prepare a piece for autumn sowings of Onions and Spinach. Winter Onions, which have not suffered from the drought, had their necks bent down some time ago, and are now approaching maturity. Autumn sowing is, in general, the only plan in our variable climate of obtaining bulbs equal in size to the largest imported ones. Our fine bed or quarter of spring-sown Onions is holding on well, but unless we have rain soon the bulbs will be small, as we cannot water them. Could we have conducted a water tub along the rows some weeks ago, the Onions would have been magnificent. Our last-year's summer crop, though sound and keeping well, were deficient in size of bulb, owing to the excessive drought. Even yet a good rain would help to swell our Onions considerably, as the tops are still of a bright fresh green.

Instead of planting out, we have shaded beds of Lettuce, Endive, Cabbage, Coleworts, and Cauliflower with branches of trees, and a great part of our work has been watering successions of Peas, Beans, and Cauliflowers where it was most needed, mulching the ground, or turning over what mulching was there, immediately afterwards. Mulching is the most effective and safest plan when the covering is broken often enough in proportion to its thickness.

To save watering, and prevent the plants running to seed, we have put a few green branches among the beds of Celery. Anything does for this purpose. A branch of a deciduous tree or shrub is quite as good as an evergreen, as the leaves hang on when withered. This shading is most needed for fresh-planted rows and beds. A few branches will save many a pailful of water. In some cases we have strewed a little litter and short grass among the plants to prevent excessive evaporation from the soil. Where the plants are large enough, a little dry earth from the sides, scattered over the soil an hour or so after watering, would be equally effectual; but, for reasons frequently given, we do not approve of doing what may be called earthing-up early Celery until three weeks or a month before it is wanted, chiefly because the bit-by-bit earthing-up system is one of the best means of securing dryness at the roots when, in sunny weather, there is a copious evaporation going on from the foliage.

In warm places a last sowing may still be made of early *Peas* to come in late, as Carter's Early, Dickson's Early, Sutton's Ringleader, &c. Talking of Peas, we saw at Luton Hoo the other day, a splendid row of Laxton's Supreme, a fine green Marrow of excellent quality, of moderately quick growth, an abundant bearer, and coming in early—about the same time as McLean's Advancer, which is also an excellent early Pea with the Marrow flavour. Next to it was a fine row of Laxton's Prolific, also a good Pea, but there seemed to us to be more than one variety in the row, and we could not, therefore, speak so confidently. We have tried in our time to save seeds of favourite Peas true, and we know how difficult it is to do so, unless a good piece is appropriated to one variety and the Peas carefully looked over, and every intruder, or even every inferior or sickly plant, at once removed. One reason why we must have new varieties is, that from mixing and sowing somewhat indiscriminately, the old ones lose in time their distinctive qualities. There is one exception to this, so far as we know, and it is Knight's Dwarf White Marrow Pea. This at the present day is rather a small Pea, but there is hardly a sweeter one in existence, and in small gardens it is very suitable, as it seldom grows above 4 feet in height, and generally yields a mass of Peas from the ground upwards. We generally grow a little of it, and it seems always to be true, though we obtain the seed from the trade; we can safely recommend it to everyone who has a taste for high quality, instead of mere size of Pea. For a large Pea, we grew Jeyes's Conqueror largely for years. It is synonymous with the Ne Plus Ultra, and a splendid large green Pea, so good that several cooks have told us, that the addition of a little sugar, so improving to other Peas, spoiled it. It is, however, a tall grower even with stopping, reaching with us to from 7 to 9 feet; this is a great drawback, and though we have not given it up, it has made us fall back more on such kinds as Veitch's Perfection and the Dwarf Mammoth Pea. The latter grows with us about 3 feet high, and for size and flavour is a fine autumn Pea, but it must have good soil and plenty of moisture. Ours failed from dryness last season, but we have had it fine in September and the first week of October. We think we have told the tale before, but it will bear repeating. One of the best judges of a thoroughly good Pea we ever knew, came to us and said, "Why, I am surprised you should send such huge old Peas to my table." "Did you taste them?" "Not I, the sight was quite sufficient for me." It was only by bringing pods, and showing that the large Peas were like marrow or butter for softness, that he could see that for once he had made a great mistake. This, no doubt, was partly owing to the fact, that there had dined with him some gentlemen who told us that they had partaken the night before of small young Peas in London, obtained, as they found out, by the legitimate process of shelling and riddling, at Covent Garden, thus keeping all the large ones out. Some have even told us that such riddled, skinny Peas were really very good when well cooked. We know pretty well what London Peas are, obtained from sacks in the market, after being heated, and shelled and riddled, and can say without presumption, that those who have partaken of such Peas only, know nothing of the exquisite flavour Peas yield when, even without additions, they are dressed almost immediately after gathering. When they must be sent to a distance, Peas ought always to travel in thin layers, so as neither to be dried nor heated.

Made a last sowing of Dwarf Kidney Beans in an earth pit, so that we can give a little protection late in autumn. By this means the out-door crop is much prolonged.

Owing to scarcity of room, we had planted a bed of Coleworts in one of the earth pits outside the walls, which was devoted in spring to such bedding plants as Calceolarias. We had previously run a piece of 2-feet wire netting round the space of ground, which would help to keep off rabbits. We knew there were grass mice about, which are difficult to exterminate. The first night half of the plants were cut down. It is singular, that there were beds of younger plants of Coleworts and Cauliflower a little distance off, which were entirely untouched, and the banks in that pit were riddled with mouse holes. The plantation was filled up, and the next morning no doubt could be left as to the intruders, for many of the

tops and separate leaves had been carried to, and partly dragged into the holes. We had tried poisoned pellets dropped into the holes, so that nothing else could get at the bread, but without any apparent advantage. Not wishing to be conquered we filled up the plantation afresh, dropped a cordon of tar all round the bed, and let a little fall into every mouse hole and run we could see, and not a plant has been touched since. We question if the plants have thriven any the worse owing to the taint of tar that meets you as you go near the place. Remember, however, that the fumes of tar would kill anything growing in a confined atmosphere. Mice, like rats, are very cleanly animals; the smallest speck of tar on their fur would be to them most annoying. Be the cause what it may, the tar has saved our plants. Where wireworm abounds, we know of no better means for driving it away than sprinkling the ground with tar by means of a brush in winter, when the land is in a state of rest. Long before spring the tar will have become mild enough to do no harm. Rats will soon shift their quarters if tar be placed in their holes and runs. Only tar and feather a rat, and the whole community in the neighbourhood will take the hint and be off. This will not, however, prevent a fresh colony paying you a visit.

FRUIT GARDEN.

Our Currants have been rather injured by *honeydew*, and attendant insects, the first the result of the excessive heat and dryness. After some of our hottest days we have had a light screen of clouds at night, which has prevented the deposition of dew, so much so, that early in the morning there was not enough to damp a satin slipper. We are told by several conversant with tropical climates, that this rarely happens there, as the cloudless sun by day is followed by the cloudless stars by night, and, consequently, by a plentiful deposition of dew, which greatly refreshes vegetation, and enables it to meet the exhausting effects of the fierce sun heat. We have always noticed that in such weather as last week, all vegetation seemed to be much exhausted when the bright day was succeeded by a thinly clouded night, the clouds though thin being sufficient to prevent free radiation. So much was this the case, that in a particular place where we wished to use the scythe, we could not cut with advantage on several mornings, the grass was so dry, and being rather thin it would not well stand the weight of the scythe; we therefore made a compromise, and swept off the heads of Daisies and Bents with the daisy knife, leaving the place green, but not so short as we wished.

We have layered a good many Strawberry runners in pots for forcing, but find that owing to the dryness, good runners are scarcer than usual. Our Black Prince, from which we had a good supply of fruit, is now quite flagged, and if we keep it alive we must contrive to water it. We find this hard Strawberry most valuable for preserving, but it is of all others that we know the most sensitive to drought. We used to grow Strawberries which pleased us, when we had less space for our limited amount of water, but now there are so many crops demanding it, that the Strawberries have not had their due share, and though we mulched, &c., both this season and last, we shall neither have the quantity nor the quality we used to have with comparatively little trouble.

Unfortunately we find that honeydew and green fly are beginning on our Plums and other trees, and we shall give them a good washing with clear lime and soot water to prevent the evil going farther. Mulched the pots in orchard houses to save watering, thinned the Grapes there, gave more air to the late vinery, and proceeded with stopping and removing shoots from fruit trees. Except the Plums and Currants alluded to, the trees are remarkably free from insect attacks this season. If clean water were abundant, we would wash Peach and other trees against walls in the afternoons of these hot days. Ours, for the most part, must do without this washing; for the water which as yet we can obtain is too muddy for syringing purposes.

ORNAMENTAL DEPARTMENT.

The weather has been very trying for Roses. Without watering and mulching, it is scarcely possible to keep up successions of bloom. A little *mildew* and *honeydew* have appeared among them, and some flowers of sulphur will be the best remedy for the mildew. For the honeydew nothing is better than syringing with clear soot water at night, drawing the fingers along where the insects congregate, and following in the morning with clean water. We find that such simple remedies are quite as effectual as many costly mixtures. Clear soft soap water is also good, but it must be clear enough to leave no mark of soap on the leaves. This is easily obtained by mixing up the soap with warm water, and allowing it to stand some hours previous to use, so as to leave the sediment untouched. We have lately had pillars and arches of Roses and Honeysuckles generally very beautiful, but they are now infested with honeydew and aphis, but where we cannot use the engine or the syringe freely. These attacks we attribute to our inability to soak the roots, and to the scorching sun. With a change of weather we shall have less trouble in making the plants healthy, as we do not like the idea of brushing and washing if they can be avoided.

On the principle of what was said last week, we have almost let the lawn alone, except switching it over with the daisy knife to cut down a Bent, Daisy, or Plantain. It is still moderately green, but a close shaving with the machine would soon help to brown it under such a sun.

Pillar Roses have been deprived of their fading flowers, and Hollyhocks, herbaceous plants, Dahlias, &c., secured, and watered when water could not be done without. Hollyhocks must take their chance, and as yet show little signs of suffering. We were obliged to water Calceolarias and Verbenas, and we slightly mulched the scarlet Pelargoniums, which we hope for some time will make them independent of watering. Re-arranged plants in corridors and in the conservatory, as, owing to painting, &c., they were a little disordered. Thinned-out Passion-flowers in the conservatory, as they were becoming too dense for the plants beneath them. Scarlet Pelargoniums of many varieties, Fuchsias, Heliotropes, large-flowered Pelargoniums, Coleuses, and Begonias were what we chiefly depended on for fresh plants; and the Pelargoniums and other plants taken out will be exposed to the sun for a short time, to harden and ripen them before pruning them. The first and second lots have been already pruned, and this brings on a general succession in different stages naturally, as the first lot are nicely broken, and may be repotted shortly. Many Pelargoniums have been repotted for autumn display, and the youngest-struck will be potted to succeed them. Scarlet Pelargoniums potted now, and intended to bloom in winter, should not be allowed to flower at present.

It is still time enough to sow annuals for late-autumn-blooming. Such as Sweet Alyssum, Candytufts, Collinsias, Nemophilas, &c., were last year useful to us for cutting up to Christmas. Wallflowers to bloom in winter, should also be potted. Almost all kinds of Pelargoniums fresh potted will do better in a shady place out of doors for two months hence than under glass. Worms, however, are apt to enter at the hole in the bottom of the pot. The simplest plan to prevent this is to use a good-sized crock, with the convex side over the hole in the pot, and with drainage over it. This will allow water to pass, but prevent the smallest worm entering.—R. F.

COVENT GARDEN MARKET.—July 28.

Increasing supplies and a falling market, the importations from France and the Channel Islands being unusually heavy. All the bush fruit, however, commaod a fair price, being of excellent quality this season. Strawberries from the Valley of the Thames are over, but an excellent supply has been furnished from Kent.

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writere of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely to The Editors of the Journal of Horticulture, &c.*, 171, *Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and convenieutly, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questione must remain unanswered until next week.

Twenty-five Roses for Yorkshire (*Emma*).—"Buy these on 3-feet standards, and plant in November. I have put, as wished, every third Rose blush, white, or yellow. 1, Charles Lefebvre, crimson; 2, Madame Clémence Joigneaux, rosy red; 3, Gloire de Dijon, orange yellow; 4, Prince Camille de Rohan, maroon; 5, Baronne Prevost, rose; 6, Baronne de Maynard, white; 7, Madame Victor Verdier, brilliant red; 8, Dr. Jamain, maroon; 9, Marguerite de St. Amand, blush; 10, Lady Suffield, rosy purplish crimson; 11, Dr. Andry, crimson; 12, Triomphe de Rennes, yellow; 13, Alfred Colomb, bright red; 14, W. Griffiths, salmon pink; 15, Caroline de Sansal, blush; 16, Duc de Cazes, purple crimson; 17, Jules Margottin, bright light crimson; 18, Céline Forestier, yellow; 19, Maréchal Vaillant, purplish red; 20, John Hopper, light rosy crimson; 21, Madame Alfred de Rougemont, white; 22, Madame Boutin, crimson; 23, John Keynes, red, maroon shaded; 24, Marguerite Bonnet, fleshy white; 25, Maurice Bernardin, vermilion crimson. I do not recommend Briar standard Roses, unless the soil is rich and unctuous. I know the above Roses chiefly on the Manetti stock, which is the best stock for light and inferior soils. I do not recommend Tea Roses out of doors for Yorkshire. Instead of those you name buy the following, they are the cream—Devoniensis, Souvenir d'Elise, Souvenir d'on Ami, Madame Willermoz, and the new Rose Adrienne Christophle. The hardiest Tea Rose known is Sombreuil. It is a fine white Rose, but it is not so good a flower as Madame Willermoz. Sœur des Anges and Ducheese d'Orléans are beautiful blush Roses, and do well on the Manetti stock here; but I doubt their doing well, especially on a Briar, so far north as Yorkshire.—W. F. Radclyffe."

Hybrid Perpetual Roses at Dalston (*G. B.*).—The following will succeed in your neighbourhood:—Anna Alexieff, Baronne Prevost, Auguste Mie, Beauty of Waltham, Charles Lefebvre, Comtesse de Chabrillant, Général Jacqueminot, John Hopper, Victor Verdier, Jules Margottin, King's Acre, Lord Clyde, Prince Camille de Rohan, Princess Mary of Cambridge, and Senateur Vaisse. They would all do better for your purpose on their own roots, and good plants may be had at 15*s.* per dozen.

Roses near Manchester (*Young Amateur*).—"As your land is light and sandy, procure your Roses on the Manetti stock. Mix plenty of thoroughly decayed dung with the soil. Of conrse, in such hot dry weather as the present, you must water them copiously at the roots and over the foliage. When Roses are coming into bloom a canvas shelter against the sun would be highly advantageous. All Roses intended for exhibition should be shaded and their blossoms kept dry. Both the Cloth of Gold and Maréchal Niel are generally (not universally) better suited for culture under glass than outside of it. When you plant your Manetti Roses, cover the collar of the bud with at least 2 inches of soil. Tread the earth close to the stock.—W. F. Radclyffe."

Roses Suitable for Pillars (*P. R.*).—"The best autumnal Roses suitable for verandah pillars 14 or 15 feet high, and having yellow, dark, and light-coloured flowers, are—*Yellow*, Céline Forestier, Triomphe de Rennes, and Gloire de Dijon. *Dark*, Duc de Cazes, Prince Camille de Rohan, and Empereur de Maroc; it is doubtful whether either of these Roses would grow that height, Duc de Cazee might reach it. *Light Roses*, Acidalie, white (Bourbon); Baronne Prevost, or Anna Alexieff, both rose-coloured; and Jules Margottin, cerise, or Charles Lefebvre, variable crimeon. The loftiest dark Rose is Frederick II. (Hybrid China); but it only gives one scries of flowers.—W. F. Radclyffe."

Goose Grass (*Forenaughts*).—It is commonly called Cleavers, because its seed vessels, covered with small hooks, cleave to the coats of animals and the dresses which come in contact with them. It is the Galium aperine of botanists, and you must consult some work on British plants. It is common in hedgerows where the soil is moist. Children pass its rough stems over their tongues to cause a slight bleeding.

Deep Well (*Old Soldier*).—There would be no difficulty to prevent your raising water by means of a forcing-pump, and distributing it over your garden by tubes, but you must consult some pump-fitter in your neighbourhood. We cannot form any opinion as to the expense.

Spanish Plants (*An Amateur*).—We know of no other method for effecting your purpose than advertising.

Sowing Carnation Seed (*C. R. W.*).—The best time to sow the seed is spring, so that good plants may be obtained before autumn, transplanting them when large enough to handle, and again before autumn. Let them have a bed in a sheltered situation, allowing 1 foot between the plants. The seede should be sown in a pan or pot, and to ensure their speedy germination they may be placed in a gentle hotbed. When the plants appear the pot should be placed near the glass, and air given freely, so as to keep the plants from becoming drawn up and weak. You may, however, now sow the seeds in a cold frame or in the open ground, covering them with a hand-glass, and if they be pricked off when large enough, and planted out next April, they may flower late next year. The Lobelia reached us in so withered a condition, that we could form no judgment upon it, except that it is white and blue. Good specimens should be sent packed in damp moss.

Choice of Strawberry Runners (*C. J.*).—We can assign no scientific reasone why the second runner from a Strawberry plant should be most productive, further than this, that the extreme of fruitfulness and the extreme of luxuriant growth are generally opposed to each other, and there can be little doubt that the first runner is the strongest and most luxuriant. We have been at such trouble and cost in seasons like the present to obtain runners, that we take all we can, but we found a difference when we kept them distinct. A fact is not less a fact, though we be unable to assign the "why."

Conservatory Arrangement (*E. B. B.*).—Considering you have no other house in which to bring plants on, we doubt if you can do better than keep the stage, and devote the north wall to Ferns; but you may set the plants thinner on the stage, and thus have larger plants. For mere ornamental display, the best plan would be to do away with the uniformity of the stage, and have baskets or vases in the house, with walking space round them. We have seen small stages thus used with good effect, so that you could walk round them. Even with a common stage you can make great variety by the arrangement of the plants, so as to produce a fresh appearance every week or fortnight.

Ventilating a Greenhouse (*H. B.*).—We see no reason why your house should not answer very well. There will be plenty of sun for the generality of greenhouse plants if you do not use much heat in winter, but merely do a little more than exclude frost. As regards ventilation, opening half of the squares at top will be enough if you can open the four sashes in front. The best plan for the top ventilators would be to have them all connected with a rod and rachet, and then you might have all moveable. The simplest mode would be to have each ventilator pivot-hung, and opened and shut with a cord. The simplest plan for the front sashes would be to hinge them at the top to open outwards, with a small flat bar of iron attached, with holes every 2 or 3 inches in it to fit into a stud of iron inside the sill of the sash. If numbers of plants were your object, and a good show besides, then we would have a 2-feet shelf round the front and ends, a 2½-feet path, a flat trellised stage 4½ feet wide, and 3 feet from the floor. This, with a 2½-feet path, would give a base of 4 feet for a steep stage against the back wall, the upper shelf going to within 2 or 3 feet of the top. This would hold an immense number of plants with narrow shelves. The front shelf should be lower than the centre stage. You could have four Vines in the house, planted inside against the back wall, and trained down the roof. Of course, with the stage referred to, the Vines would do no good before they reached the roof. Without the stage good Grapes could be obtained on the back wall if the roof were not too much covered. With the high stage there, the best place for the Vines would be a border outside the house in front, or inside in front if more convenient. The heating with gas will do if no gas fumes enter, and the opening of the dining-room window on a cold night, after there has been a comfortable fire there, will do much. Indeed, that window would do much to equalise the heat of the dining-room and the heat of the greenhouse.

Japanese Quince (*C. P.*).—It is the Cydonia, or Pyrus japonica, so common in our flower gardens.

Grapes Diseased (*Oakwood*).—We are quite at a loss to account for the parboiled appearance of the berries of the Lady Downe's Grape as they reached us, and more especially as the Vines are so healthy, and the Grapes on other Vines not at all touched. We can do nothing but suggest looking at the glass over these two Vines, and seeing if there are burning spots.

Mildew on Grapes (*A Constant Subscriber*).—Thin them at once, and cover them thoroughly with flowers of sulphur. We have a plateful of the sulphur under each bunch, and bathe the berries, as it were, in it.

Storing Anemones (*A Constant Reader*).—We are unable to say how long they may remain unplanted; but as you have had them out of the ground for two years, and in following years they have flowered well, we think it likely they would retain their vitality for many years. Every cultivator knows how apt the Anemone is to commence growth immediately after maturation, and that tendency is often a source of anxiety to the grower. His aim is to secure for the tubers a season of perfect rest, but not to make it too long he plants in October, and at the end of January or beginning of February, or as soon afterwards as the weather and state of the ground permit. Keeping the tubers out of the ground beyond that time we consider injurious to the succeeding year's growth and bloom. The tubers should be kept in sand dried in an oven, and packed in a box so that no two touch. It should be placed in a cool very dry room.

Surface of Pond Green (*E. H.*).—You have not a sufficient number of waterfowl, otherwise they would keep the surface clear. A pair of swans would, no doubt, serve you better than anything else. In the meantime you may with a dry deal spar, and a rope tied to each end, free the surface of the greenness by drawing the spar gently towards one side, and then backwards. The vegetation can be cleared from the spar and sides of the pond.

Ants to Destroy (*New Forest*).—Mix some arsenic with treacle, spread it thinly on pieces of glass or earthenware, and lay them near the nests. You will soon be rid of the ants.

Cedar of Lebanon (*An Old Subscriber*).—The Cedar of Lebanon and all the Fir tribe succeed on chalk. Plants from 4 to 6 feet in height may be safely moved if frequently transplanted and finally removed with a good ball; indeed, they are rather difficult to transplant unless a good ball be preserved. We know some Cedars of Lebanon upwards of 60 feet high on a chalky soil.

Strawberries (*Warwick*).—We cannot recommend nurserymen. Any of the nurserymen who advertise in our columns could supply the Vicomteese Héricart de Thury. We have so many applications about this variety, that we think any nurserymen having a stock would be repaid if he advertised it.

Errata.—In the article on the loss of the Peach crop in 1869, in the second column, line nineteen from top, "produced" should be *wanting*, and in the seventh line of the second paragraph of the same column, for "made" read *unable*.

Names of Plants (*A. Y.*).—1, Selaginella Braunii (often called S. Willdenovii); 2, Doodia caudata; 3, Adiantum capillus-Veneris; 4, Polypodium appendiculatum; 5, Gymnogramma chrysophylla; 6, Pteris tricolor; 7, Cincinalis flavens, also called Notholæna chryeophylla; 8, Asplenium rhizophorum; 11, Rivina lævis. We cannot undertake to name plants from leaves only. (*T. Y.*).—Allamanda Schottii. (*H. M. K.*).—2, Asplenium flaccidum; 3, Jasminum Sambac. (*H. K.*).—Pteris tricolor.

(*An Old Subscriber*).—Homeroeallis Oava. (*S. C. B.*).—Your Fern is one of the innumerable variations of Athyrium Filix-fœmina. We believe it to be the one distinguished as "variety Pritchardii." (*W. H. E. Herbert*). Alyssum orientale variegatum. (*C. T.*).—1, Daucus esrota; 2, a Cruciferous, insufficient for determination; 3, Anthyllis vulnoraria; 4, Genista tinctoria; 5, Scandix Pecten; 6, Coronopus Ruellii. (*J. D.*).—1, Veronica spicata; 2, Spiræa Filipendula fl.-pleno. (*R. Jameson*).—Holcus lanatus. (*O. P.*).—1, Crataegus sanguinea; 2, Crataegus (or Mespilus) orientalis. (*H. M.*).—Centaurea depressa. (*T. F. H.*).—Your plants may probably prove to be as follow.—1, Leucothoe Lobbii; 2, Pieris formosa, but we are doubtful of them, and should be glad of further specimens if in bloom.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending July 27th.

POULTRY, BEE, AND PIGEON CHRONICLE.

THE POULTERS' COMPANY.

Thanks, dear Mr. Editor, for your article on poultry and poulterers. Please to keep the ball in motion, and it will roll till it come in contact with shins whose owners will wince. I shall have little to say on this occasion, but I will return to the charge. You have opened a prolific field. From their connection with birds "poulters," miscalled "poulterers"—I think it is Dr. Johnson who says, when ignorant people make a mistake they always do it by addition—hence poulter*ers*. I tell you I am only to-day in possession of your article, and have not time to go into it, but I promise you I shall return thereto. As it is, I shall flounder about among the mines of lore it lays bare. We go a long way back for choice poultry. In Holy Scripture, where detail is given of the food supplied to Solomon's table, we find "fatted fowl" enumerated. Capons belonged to the early days of our monarchy. Their good qualities were known to the "Swan of Avon." His justice is said to be "with good capon lined." To this day there is an annual trip on the Thames by the Corporation of London, called the Swan-hopping, and the water-bailiff is bound to see that all Swans within the jurisdiction of the City are marked. The manner of marking is, that when forward as cygnets they are cut obliquely through the bill till it bleeds. Instinct teaches the bird to lessen the pain and bleeding by putting its bill continually in the cold water. The purpose is soon answered, and when the wound is cicatrised there remains the mark of the cut, which can never be removed. Those who caught one of these Swans were bound to return them to the City of London. I believe Norwich by its charter is bound to consume a certain quantity of oats in fattening a number of Swans. Some must be consumed, some given away. The Corporation do not even pay the same respect to the Swans that American sailors do to horse beef—

"They eat the fat and suck the bones,
And pitch the rest to Davy Jones."

Fine idea of retribution, that the man who took the U.S. contract for navy beef and supplied horseflesh, is in a future state compelled to eat it for ever.

I do not know how it is, but when August is nigh and the sun is hot, we feel disposed to be lazy, and to take our time, and would rather wander into twenty tales, giving a part of each, than keep stedfastly to one. Well, I was asked once to dine in Essex from a Norwich Swan. I do not like a dinner of one dish. Venison may be tough, or high, or worse. Fancy a dozen sitting down to a haunch that reveals its presence at a distance and from under a cover, and becomes simply unbearable on a closer acquaintance. It is vulgar in the present day to quote "Peregrine Pickle;" but who has not sympathised with the carver when at "the feast after the manner of the ancients," and when he had tucked the tablecloth into his waistcoat preparatory to carving the dish on which the host "himself much prided,"—"the belly of a newly farrowed sow stuffed with liver, garlick, pennyroyal and other condiments," he sprang from the table exclaiming, "This is the essence of a bed of garlic!" Unfortunately he dragged the tablecloth with him, to the great discomfort of the guests.

But the Swan. There were learned quotations about royal dishes—the Swan, the Peacock, the Heron, the sturgeon, and the boar's head; but the Swan had the advantage. Did not Penelope sing of her Swans? Had they not always been the portion of the upper classes? Every man felt he could extinguish any talkative fellow at a table by saying, Have you eaten Swan? How do you like it?—B.

(To be continued.)

BLACK-BREASTED RED GAME FOWLS.

Last year at the meeting of the Hampshire Ornithological Association which took place at Southampton, some little amusement was caused by a few Brahma breeders stating it was not possible to get up an amateur cup for Black-breasted Red Game, whilst such a cup could easily be provided for their pets. I, as Vice-President, happened to be present, and at once took up the challenge. The result is that I intend, should the subscriptions reach a sufficient amount, to offer two cups, one of ten guineas, and one of five guineas for the first and second pens of Black-breasted Red Game chickens of 1869, and am pleased to say have been most warmly supported by Messrs. Gibson, Stagg, Matthews, Hodgkinson, Ames, and Loe, who, together with myself, at once subscribed a guinea each. The reason for restricting the competition to chickens is, that it is unfair to place them in competition with more mature birds whose size gives them every advantage.

The conditions of competition are as follow:—The birds must be Black Red Game chickens of 1869, shown in pens of a cockerel and one pullet. The subscription to be one guinea, without prepayment of which no exhibitor to be eligible to compete. Entry fee the sum usually paid for ordinary pens.

It would be almost impossible personally to apply to each breeder, but I am convinced that there are many who would gladly subscribe their guinea if the subject were properly brought under their notice. I shall feel obliged if any gentleman who would like to join us would kindly write me; and as it is in contemplation to form a Black-breasted Red Game fowl club, I shall be glad of the names of those who would like to become members, and any suggestion they might offer as to formation, &c., would be most acceptable.—H. C. Dear, *North Stoneham Park, near Southampton.*

BIDEFORD AND NORTH DEVON POULTRY SHOW.

The following are the awards at this Show, held on the 22nd inst.:—

Dorkings (Coloured).—1, G. M. Walsh, Halsdon, Dolton. 2, 3, and *hc*, A. C. Thynne, Penstowe, Stratton.

Dorkings (White).—2, C. Hamlet, Bideford.

Spanish.—1, S. R. Harris, Cosgarne, St Day. 2, Tonkin & Tuckey, Bristol. 3, W. Norsworthy.

Game (Black and Brown-breasted).—1, E. C. Pope, Falmouth. 2, N. Treleven, Stratton. 3, W. W. B. Coham, Dunsland, Brandiscorner.

Cochin-China.—1, J. H. Dawes, Birmingham. 2, W. L. Trewin, Kilkhampton, Stratton. 3, Mrs. J. Milward, Newton St. Loe, Bristol. *hc*, H. Stephenson, Lympsham Rectory, Weston-super-Mare.

Brahmas.—2, Mrs. A. C. Thynne. 3, L. H. Ricketts, Banwell. *hc*, Mrs. A. C. Thynne; J. Heal, Parkham. *c*, S. R. Higham, Morchard Bishop.

Hamburghs (Gold-pencilled).—1, S. R. Harris, Cosgarne.

Hamburghs (Gold-spangled).—1, S. R. Harris. 2, J. Medway, Nowton Abbot. 3, Woodley & Banbury, Stratton.

Hamburghs (Silver-spangled).—1, S. R. Harris.

Hamburghs (Silver-pencilled).—1, S. R. Harris. 2, J. Walters, Bideford. 3, R. A. Treleven.

Polands.—1, W. L. Trewin.

EXTRA PRIZES.

Barndoor or Cross Breed.—1 and 3, J. B. Lyle, Grimscott, Strstton. 2, J. Heal, Parkham.

Any Pure Breed not Mentioned Above.—1, J. Francis, Worth (La Flèche). 2, Miss S. H. Northcote, Upton Pynes, Exeter (White Spanish). 3, T. Therston (Black Hamburghs). *hc*, H. Leworthy, Newton, Barnstaple (White Minorcas). *c*, W. Gibson, Bideford (Black Minorcas).

Any Pure Breed.—*Cock.*—1, F. Brewer, Lostwithiel (Black Minorca). 2, Mrs. J. Milward (Cochin-China). 3, W. L. Trewin (Cochin-China).

Any Pure Breed.—*Chickens*—1 and 3, H. Stephenson (Coloured Dorkings). 2, L. Patton, Hillmore, near Taunton (Coloured Dorkings). *hc*, G. M. Walsh, Haledon, Dolton (Dorking); L. Withecomb, Buckland Brewer (Silver-spangled Hamburghs); Mrs. A. C. Thynne (Dark Brahmas); J. Heal (Brahmas); E. Maunder, sen., Northmolton (Black-breasted).

Game Bantams.—1, E. A. Bazeley, Bideford. 2, T. Taylor, Bideford. 3, J. O. W. Scott, Smytham, Torrington.

Bantams (Any other sort).—1, S. Woodman, Barnstaple. 2, J. H. Dawes. 3, S. R. Higham, Morchard Bishop.

Guinea Fowls.—1 and *c*, W. M. Lancaster, Thuborough. 2, W. Pridham, Barnstaple. 3, J. S. Willett, Monkleigh.

Ducks (Aylesbury).—1 and 3, J. Heal. 2, G. M. Walsh, Helsdon, Dolton.

Ducks (Common, or any other sort).—1, L. H. Ricketts (Rouen). 2, L. Patton (Rouen) 3, J. Oliver, Bideford. *hc*, J. S. Willett, Monkleigh; Miss Turner, Abbotsham (Muscovy). *c*, R. Petherbridge, Ham, Alverdiscott (Wild).

Geese.—1, J. Bear, Parkham. 2 and 3, J. Heal.

Turkeys.—1 and 2, L. Patton, Hillmore, near Taunton. 3, Miss Galsworthy, Kilkhampton. *hc*, Mrs. J. Milwood.

Rabbits.—1 and 2, C. Seale, Tiverton (Grey White, and Lop-eared). 3, H. Parsons, Bideford. *c*, F. Oliver, Bideford (Himalays).

PIGEONS.

Carriers.—1, G. S. Hockey, Durdham Down, Bristol. 2, H. Yardley, Birmingham.

Barbs.—1, H. Yardley. 2 and *c*, L. Smith, Newport, Barnstaple. *hc*, W. Westacott, jun., Barnstaple.

Pouters.—1, H. Yardley,

Fantails.—1, H. Yardley.

Jacobins.—1, W. Westacott, jun. 2, J. Chapple, Bideford.

Trumpeters.—2, W. Mudge, Torre, Torquay.

Tumblers.—1, H. Yardley. 2 and *hc*, W. Westacott.

Turbits.—2, H. Yardley.

Nuns.—1, H. Yardley.

Common.—1 and 2, T. Boundy, jun., Rudha Bridge Mills (Blue and White).

Judges.—Rev. G. F. Hodson, and Capt. Adney.

HESSLE POULTRY SHOW.

(*From a Correspondent.*)

The fourth annual Exhibition of this Society took place on the 15th ult., in the grounds of J. S. Fearne, Esq. The day being fine, and the North-Eastern Railway Company running specials from Hull, caused a great number of visitors to patronise the Show The entries for poultry were large, and some first-class specimens were exhibited, more particularly in the *Game*, *Spanish*, and *Polish* classes. *Pigeons* were also well represented, except in the Carrier class, in which the entries were very meagre.

Spanish.—1, G. Holmes, Driffield. 2, T. C. & E. Newbitt, Epworth. *Cock.*—1, G. Holmes.

Dorkings.—1, G. Holmes. 2, J. Thompson.

Cochin-China.—1, R. W. Richardson. 2, W. Charter. *Cock.*—1, R. Robson.

Game (Black-breasted or other Reds).—1, H. M. Julian. 2, W. Boyes. *Cock.*—1, H. M. Julian.

Game (Any other variety).—1, W. Boyes. 2, H. M. Julian, *Cock.*—1, H. M. Julian.

Polands.—1, Miss E. Proctor. 2, J. M. Proctor. *Cock.*—1, Miss E. Proctor.

Hamburghs (Golden-spangled).—1, T. Holmes. 2, R. Fleming. *Cock.*—1, G. Holmes.

Hamburghs (Golden-pencilled).—1, M. Barron. 2, G. Holmes. *Cock.*—, G. Holmes.

Hamburghs (Silver-spangled).—1, T. Holmes. 2, G. Holmes. *Cock.*—1, O. A. Young.

Hamburghs (Silver-pencilled).—1, T. Holmes. 2, G. Holmes. *Cock.*—1, G. Holmes.

Game Bantams.—1, G. Holmes. 2, J. Hatfield. *Cock.*—1, J. Duggleby.

Bantams (Any other variety).—1, Miss B. A. Wilde. 2, Mrs. T. Wilde.

Extra Stock.—1, R. Lott. 2, G. Lott.

Selling Class.—1, Pickering & Marshall. 2, J. Hall.

Ducks (Aylesbury).—2, O. A. Young.

Ducks (Rouen).—1, G. Holmes. 2, O. A. Young.

Ducks (Common).—1, O. A. Young. 2, W. Charter.

Pigeons.—*Dragoons.*—1, H. Taylor. 2, H. Lawson. *Carriers.*—1, J. Thompson. 2, W. Campey. *Croppers.*—1, J. Thompson. 2, T. Statters. *Trumpeters.*—1, C. Lythe. 2, R. Lythe. *Jacobins.*—1, C. Lythe. 2, H. Lawson. *Fantails.*—1, C. Lythe. 2, R. Lythe. *Tumblers.*—1, S. Holloway. 2, J. Wood. *Barbs.*—1, H. Thompson. 2, T. Statter. *Nuns.*—1, C. Lythe. 2, Pickering & Marshall. *Any other Variety.*—1, R. Lythe. 2, H. Lawson.

Rabbits.—*Lop-eared.*—1, P. Ashton. 2, G. Ashton. *Any other Variety.*—1, S. M. Fletcher. 2, D. Banuister. *Heaviest.*—1, Miss Herbert.

The Judges were Messrs. Pickering and Hodgkinson, Hull.

The Middleton Agricultural Society.—The annual Show of this Society is fixed for Thursday, the 16th of September next. Many alterations and additions have been made in the prize list, and the premiums increased by £200, making the total amount now offered nearly £1100. The great success which attended the exhibition of last year, has caused the Committee to enlarge the prize list for all descriptions of live stock, agricultural and horticultural produce, implements, bees, &c. The greatest change, however, is to be seen in the poultry department. There the whole of the prizes for full pens have been largely augmented, and a few new classes have been created. Four out of the thirteen silver cups offered for poultry are for Game fowls, and in this class a curious addition has been made. A gentleman connected with the Show offers prizes for the best Game cock above twelve months old, any breed, to be shown with his full comb and wattles on: first, £5; second, £2; and third, £1. We see from the rules that exhibitors winning silver cups may have the money instead, if application be made to the Secretary within a given time from the Show. For bees, £8 are offered; and in the plant department the prizes have also been increased. It will, however, be impossible for us to give a detailed list of the additions made in the premiums, and we must refer our readers to the catalogue of prizes for further information. Last year the entries numbered nearly 3500.

WHITE STARLING—SCALY-LEGGED FOWLS.

I saw a white Starling a few years ago in a large flight of Starlings, but could not get a shot at it; it was just before corn harvest. It was a young bird, but whether it would have moulted dark I do not know, for though Starlings generally return to the same district the following year, I never saw it again. In your "Letter Box" (page 54) I noticed an answer respecting scaliness on legs. I have it often in Cochins, and use a mixture of sulphur and oil, which always puts them right.—W. Gamon.

LIMITING THE PRODUCTION OF DRONES.

As there is no doubt that the only purpose of the existence of the male element among bees is the fecundation of young queens, it follows that, at any rate under ordinary circumstances, the production of these profitless consumers of the wealth of the community may be limited with advantage. My attention has been directed to this subject by the fact that my own bees have this season manifested a more than usual proclivity for the construction of drone combs, and as I find from inquiries made by others that they have not been singular in this respect, I deem it worth while to occupy a small space in the columns of "our Journal," by discussing the most feasible mode of limiting the numbers of this non-producing class.

I may say at once that the hints which I am about to give apply only to moveable-comb hives, and that in the case of hives with fixed combs I know of no practicable means of putting limits to the profitless production of drones.

In the first place, every new swarm should be looked over at intervals of four or five days whilst comb-building is going on, and during these examinations all incipient deviations from the right line must be corrected, and every bent comb straightened—a matter of little difficulty at this time, although the combs should be handled with much caution in their soft and immature condition. If it be found that some are being formed either wholly or in part of drone cells, it may occasionally be well to transpose them, so as to bring them towards the sides of the hive, thus insuring worker combs for the "brood nest," where also they will be more rapidly extended and completed. It would probably be found worse than useless to remove them altogether, as the bees would most likely immediately set to work to replace them. If spare worker combs be on hand, or can be procured from any source, they may be fitted into frames and substituted for superfluous drone combs. I use the word superfluous advisedly, for I do not think it well to thwart nature altogether, and have for this reason always permitted a small portion of drone comb in every hive. I do not, therefore, know what might be the effect of excluding it entirely, never having tried the experiment.

It happened this spring that I had several swarms of last year with incomplete combs and comparatively few bees. By the time they were strong enough to do much towards extending their combs the season was pretty well advanced, and all commenced the fabrication of drone cells. As soon as I discovered this I made an artificial swarm by depriving a strong

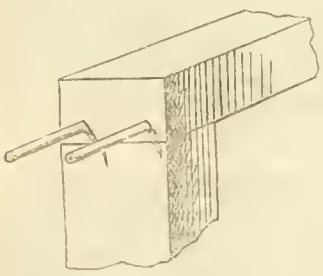
stock of every comb save one, and used the combs thus obtained to supply the vacancies in the other hives, which would otherwise have been filled with drone combs. When these other stocks, recuperated in this manner, had become strong enough, swarms were taken from them as described in page 436 of the last volume, and as soon as the young queens became fertilised, every comb but one was taken from each of the parent stocks, and, being of course free from brood, put by in store for future use.

In these proceedings it will be seen I acted upon the principle that any stock of bees may be compelled to fabricate worker combs, by being reduced to the condition of a swarm—*i.e.*, deprived of all, or nearly all, its combs. This is especially the case if the bees have a young queen of the current year, as in this case we may rely upon it with perfect certainty that they will build but little, if any, drone comb.

The simple excision of drone brood during summer may be considered almost a useless operation unless the vacancy can be at once filled with worker comb by the apiarian, for if left to themselves the bees will only waste time and material by replacing the abstracted cells, which the queen will at once occupy with drone eggs.—A Devonshire Bee-keeper.

PREVENTING BEES FASTENING BAR FRAMES TO THE HIVE.

While discussing in "our Journal" improvements in bar frames, will you allow me to ask your readers if they have ever tried them with two wire pins to support the frames, instead of carrying the wooden bar to the full extent? thus—



I find that my bees in the whole of my frame hives (ten) fasten the ends of the bars, and even now I cannot take one out without giving the hive a shake that sends a cloud of bees into my face. How it will be when this hot weather ceases, and the propolis sets, I do not know. If it has been tried, I should be very glad to know through your columns with what results. I fancy it would be an improvement.—T. B. H.

[Frames may be taken out without any jerk whatever by moving them gently a little out of the perpendicular before lifting them. This cannot, however, be done when they are confined at the bottom by a notched bar, which, therefore, should never be used except for travelling, or when the hive is first tenanted by a swarm.—A Devonshire Bee-keeper.]

FAILURES IN BEE-KEEPING.

The "Kent Bee-keeper's" difficulties are very much what we have to contend with here; for I conclude that his locality is not a very favourable one. I think many of my neighbours might write as he does; perhaps I might once have done so myself.

In the present advanced state of apiarian science there are very few localities in which bees may not be kept so as to afford both pleasure and profit.

The first thing for the "Kent Bee-keeper" is to learn Mr. Filleul's system of getting strong or double swarms, and avoiding second swarms or casts; but even then he may sometimes require to give further strength to his swarms. For instance, my first swarm this year came out on the 24th of May, was put into a Berkshire hive, and set at once in the old stock's place; but, notwithstanding, six weeks afterwards, owing to the cold weather, it was doing so badly that I determined to strengthen it by adding another small swarm. The progress since has been marvellous; the hive is full, and I have had to put on a super, in which the bees are now working.

But to return to the old stock from which the swarm issued. At first it appeared depopulated, and was so deficient in food that I was alarmed for its safety; I therefore gave it a few pounds of sugar syrup to help it till the young bees came forward. It has not sent out a second swarm, but is very strong, so much so as to require the addition of a second glass or super.

If the "Kent Bee-keeper" will invest 6*d.* on Mr. Filleul's "Profitable Bee-keeping," and 4*d.* on "Bee-keeping for the Many," and read the articles and letters on bees in the Journal, he will, I doubt not, be able before long to write a very different account of his apiary.

One more remark, and I am done. Let him be sure to keep his hives well shaded.—S. B.

OUR LETTER BOX.

Brahma Pootra Cock's Tail (*H. M. G.*).—Nothing will make the cock's tail grow faster, but it will grow independently of moulting. Feathers accidentally lost are replaced at once, irrespective of season. A tail grows in about six weeks.

Preparing Fowls for Exhibiting (*Idem*).—Wash their combs and faces with cold water and vinegar, their legs with soap and water; soot will wipe off with a damp sponge. The best food for them is ground oats. They are difficult to get. Oatmeal and barleymeal are both good food, and a few peas given daily for a week to prove plumage.

Dorkings and Pencilled Hamburghs (*R. H. F.*).—We cannot approve your cross. You will not find the Dorkings constant sitters if you keep young birds every year. We believe they are as useful as any fowl, and if fowls are wanted as well as eggs, we do not know how we are to improve them. If you wish to cross, cross with Game or Brahmas, but recollect a supply of eggs is more a question of age than breed. Pencilled Hamburghs are Chittiprats, but the Spangled are called the Pheasants.

Points in Silver-spangled Hamburgh Cocks (*Hamburgh Cock*).—We should prefer a medium comb to either of them; nevertheless, the widest is not too wide, and if well and firmly set on the head, well spiked, and piked behind, we should prefer it to the narrow one. The spangles on the breast should be large but distinct. Splashing and mossing are bad. The ear-lobe should not be larger than a sixpence. A fourpenny piece is large enough. A very large one is a fault, and has a tendency to flush round the edges.

Spanish Cock's Comb and Face (*Idem*).—Spanish cocks get white faces much earlier than pullets. We should look with apprehension on the drooping tendency of the comb. It is a great objection. The only remedy is to tie it in position with silver wire, running it through the top of the comb and fastening to the base.

Dari as Food for Poultry (*W. M. K.*).—It is called "Dari." It comes from Egypt. It is poor feeding stuff and used only when mixed with other and better "stuffs." It has no quoted value in England.

Halifax Poultry Show (*Subscriber*).—We do not know. It has not been advertised.

Tumbler Pigeons (*H. E., Bromley*).—No Tumblers perform the feat of tumbling until they are adult; young will do well, if of a tumbling breed, when they are quite grown up and mated. No doubt you feed them too well; they are, therefore, fat and indolent. Drive them up on a clear morning fasting, and they must always be driven up, unless they have been shut up for a long time, when they will delight in a high fly. Sometimes in particular states of the atmosphere they, like other birds, will fly high, and when they are feeding-off their young; but, as a rule, they must be driven up. Rather coarse-bred birds are best for high flying. Food with Tumblers is a matter of no consequence, as the flying sort eat anything, but it is best to vary the diet, or mix peas, Indiancorn, and barley.

Incubator (*P.*).—Apply to Baily & Son, 113, Mount Street.

Ducks Weak-legged (*B. K.*).—We should be afraid they roost on brick, stone, or board, either will cause the cramp from which they are suffering. It is not weakness. Shut them for a few days in a dry place, an old pigstye will do. Let it be well littered with dry straw, and feed them on oats, sods of grass, and gravel, put in a milk-pan and covered with water. If they have been roosting, as we expect, that is the cause, and if removed they will soon use their legs again.

Preserving Eggs (*A Subscriber; A Novice*).—The directions given are in our No. 422.

Leicester Pigeon and Bird Show (*A Subscriber*).—In one class there was only your own entry, and the judge disqualified it through no competition, at the same time amongst the birds there were several classes with only one entry, and to them were awarded first prizes. You consider you are entitled to a first prize, or, at least, to have your entry money returned, which is refused. We cannot give an opinion without seeing the rules issued by the Committee, and without knowing whether the judges thought the birds undeserving of a prize.

Stocks never Swarming (*J. H. T.*).—We should transfer the bees-combs and all, to a frame hive in the manner described by Mr. Woodbury in page 72. You may then in the autumn strengthen them by the addition of the population of a condemned stock, effecting at the same time an exchange of queens if deemed desirable, and next year swarm them artificially in the manner described in page 84 of "The Gardeners' Almanack."

Bees Working in the Hive Cover (*Novice*).—In the hive (a glass one of Neighbour's), with a straw cover to lift off and on, in which cover the bees are working, as well as in the glass, we should let the bees work on until the end of the season; then expel them by driving, and appropriate the contents of the straw cover, returning the bees to the stock hive.

Ligurian Stock Dwindling (*B. K.*).—It seems probable that your Ligurians swarmed unperceived some time in May, and that the stock is now queenless owing to the young queen having met with some accident during one of her wedding-flights. Queenless bees are often very irascible, but with the aid of a little smoke and snuff entire protection by means of a bee-veil and gloves, there can be no real difficulty in lifting out the combs, and in this way ascertaining their true state. If on examination our conjecture proves to be correct, we should endeavour to supply the deficiency by the addition of a late swarm. There is, however, yet another hypothesis —*i.e.*, that the stock is infected by foul brood. This, also, can only be verified by an internal examination.

Pagden on Bees (*F. H.*).—No publisher's name is attached to the book. It should be advertised.

From observations taken near London during the last forty-two years, the average day temperature of the week is 74.4°; and its night temperature 50.5°. The greatest heat was 93°, on the 10th, 1842, and 2nd, 1856; and the lowest cold 33°, on the 11th, 1864. The greatest fall of rain was 1.08 inch.

THE POT-CULTIVATION OF THE FIG.

THE collection of Figs now in the possession of the Royal Horticultural Society at Chiswick extends to over 130 varieties, and it is, perhaps, the most complete in existence. Thirty varieties were exhibited at the Manchester Show as an example of what may be done in the way of cultivating them in pots, which is the method adopted by the Society in proving this class of fruits.

The following remarks are intended to apply chiefly to Fig trees grown in pots. There is no mode of culture which has so many advantages, and none for which the plant itself is so particularly well adapted. One great recommendation of pot-culture is the immense variety that can be grown in a very small space, so that by a proper selection of varieties an almost continual supply may be obtained. The Fig bears more profusely in pots than when planted out, excepting in the case of large old trees. The Fig is a gross feeder, and when planted out it is difficult, especially while the plants are young, to restrict the action of the roots; and thus, instead of fruit, nothing but gross shoots are produced. Plants in pots, on the contrary, are perfectly under the control of the cultivator, and bear fruit abundantly. Further, the fruits produced from plants in pots are generally of a far richer and higher quality, if proper attention is paid to watering, &c.

One of the most puzzling circumstances in connection with Figs is the casting of the fruit, which is very prevalent with plants in pots. Many theories have been advanced, and many articles written as to the probable cause of this, and how to prevent it, but with little practical result, for as yet nothing definite has been arrived at. It is, without doubt, due to some defect of the setting, yet how or from what cause this defect arises I have never been able to determine. Some varieties, even particular trees, are more liable to cast their fruit than others, and that under all kinds of treatment; while others receiving the same treatment in every respect do not cast them. It is not the sickly trees that are so much subject to the evil, neither is it the gross-growing ones, but generally those which seem in the best possible condition. It is the first crop, too, more rarely the second, that is cast. It is ascribed by some to a sudden check, to coldness, to dryness at the root, or the reverse, or to too much moisture at the time of setting the fruit. All of these conditions are injurious to a certain extent, yet none of them sufficiently accounts for the evil. It is not coldness, as the evil generally occurs at the warmest season of the year. It is not dryness at the root, nor excessive moisture, as I have had plants subjected to each extreme—the one potbound and flagging nearly every day, the other with the pot and roots standing in a pan of water, and in neither case did the tree cast its fruits; while others alongside, treated in the usual manner, did so. There are two or three trees at Chiswick which invariably cast their fruit every year, in spite of every precaution.

Although Figs will grow in almost any situation, there is no plant more benefited by the full and direct rays of the sun; the Fig house, therefore, should be of a light and airy description, so that the plants may be fully exposed to the sun's influence, for on that depends the proper ripening of the wood and the production of the future crop, as well as the flavouring of the fruit. A vinery, or some such place, in which to start them into growth in spring, is very suitable. The plants may remain under the Vines until they are in full leaf, when they must be removed to more sunny quarters. Fig trees while growing delight in a close, moist, warm atmosphere. In order to start them into growth a temperature of 50° by night will be sufficient; as the plants advance, the temperature may be gradually increased to 65° or 70°. During the summer very little fire heat will be required, as by closing the house early in the afternoon a very high temperature may be maintained by sun heat alone. By day the temperature, if by sun heat, may be allowed to rise to 90°, 100°, or even higher, keeping the atmosphere very moist by frequently syringing all over the plants, paths, &c., even in the bright sunshine. In fact, the warmer and moister the atmosphere is the better the plants seem to thrive. By this mode of treatment red spider, thrips, &c., the great scourges of Figs in a dry atmosphere, are effectually kept in check.

The assistance of fire heat is very little required for Figs during the summer, only on very cold nights and to assist in ripening the fruit of the later varieties. When the fruit is ripening air must be admitted rather freely, and a drier and more bracing atmosphere obtained, as Figs, like all other fruits, are much improved in flavour by having a brisk atmosphere surrounding them while ripening.

The Fig will grow in almost any kind of soil; that, however, in which it seems to thrive best, and to bear the greatest abundance of fruit, is a pretty good yellow loam, resting on a chalky or dry gravelly subsoil. For pot-cultivation I have found the following soil answer well:—Two-thirds good yellow loam, to one-third lime or brick rubbish, with a free admixture of rotten manure, charcoal, and burnt ashes. When the plants are young they should have a liberal allowance of pot-room, so as to grow them rapidly up to the required size. They will produce fruit, however, in a very small pot. I have fruited them abundantly in 6-inch pots. The most eligible size, and that which I should recommend as large enough for all general purposes is the 12-inch pot—*i.e.*, 12 inches in diameter, in which were grown those exhibited. The same trees may be grown in the same pots for a great number of years. Our practice is to repot all the trees while they are at rest during winter, shaking off a great portion of the old soil, and shortening the roots considerably in the same way as is practised with Pelargoniums. During the summer, when the pots are nearly filled with roots, much benefit will be derived from frequently top-dressing with rotten manure mixed with a little loam.

Figs while growing freely require a very liberal supply of water; indeed, if the pots are tolerably full of roots they can scarcely be over-supplied. Manure water may also be applied with advantage. When the fruit is ripening,

however, water must be applied more sparingly, as an overdose at that time will deteriorate the flavour, and cause many of the fruits of the finer varieties to split open, especially in dull, cold, cloudy weather. Great care is therefore necessary in watering, &c., at this stage.

It is an old saying, that "a pruned Fig tree never bears." It is, however, like many others, only half true. The Fig tree will bear any amount of pruning; there is no plant more benefited by summer-pruning—*i. e.*, pinching off the growing shoots—than the Fig, and even in winter it may be pruned to any extent with impunity. It is true that if we cut back in winter all the shoots on which are situate the fruits which form the first crop, that crop will be sacrificed. We obtain, however, a very abundant second crop if attention be paid to the pinching of the growing shoots as closely as possible during summer. While the trees are young and vigorous the shoots will elongate considerably in spite of all the pinching. These, in winter, should be cut back to one-half their length, and the same process of close pinching continued. As the plants grow older they will make more stubby, short, close-jointed wood, which in winter will not require much pruning. Of the trees exhibited (now eight years old), most of the largest had the half of their branches cut back in winter, and the other half left unpruned, excepting when the plant became too large; then it was headed quite down, and by this means the whole of the plants were kept compact and of a uniform size. In summer the young shoots are pinched, first at from 2 to 3 inches in length, then as closely afterwards as it is possible to do so. This continuous and incessant pinching induces fruitfulness in the Fig to a very great degree. All the shoots that are pinched throw out one and sometimes several fruits at the axils of the leaves, while those not pinched more rarely do so.

Another point of considerable importance is that of forming the plant on a single stem. Independently of its more handsome appearance, I have found such plants to be much more fruitful than where a multiplicity of stems are allowed.

Lastly, with respect to the selection of varieties for cultivation. If pot-culture is intended I would recommend considerable variety—firstly, because there is a charm in variety; and secondly, because Figs vary much in flavour according to the situations or conditions under which they may be growing. For instance, some of the higher-flavoured and finest Figs require much heat and bright sunshine to bring them to full perfection, and it may happen that these conditions cannot be fulfilled; the weather may be cold and sunless, and more heat may be wanting than can be supplied—then some of the second-rate sorts surpass the better ones in flavour. Of the highest-flavoured sorts, I would select Col di Signora Blanca, Grosse Verte, and Bourjassotte grise. These, however, all require considerable heat; the last-named being, perhaps, the finest and most constantly good variety in the collection. Of the most free-fruiting kinds may be named White Ischia, Violette de Bordeaux, White Marseilles, and Brown Turkey; and for hardy varieties—varieties suitable for cultivating in the open air against walls in this country—in addition to the White Marseilles and the Brown Turkey commonly to be met with, I would venture to recommend the earliest of all our Figs, De la Madeleine, Grosse Violette de Bordeaux, and Grosse Monstrueuse de Lipari, which are all possessed of the property of "first bearing"—the term used in the Fig countries to denote those varieties which retain and ripen-off the fruit which is produced on the wood of the previous year's growth. Our summers are in general too short to allow of the Fig ripening more than the first crop, so that only those varieties which are possessed of this property (and it is peculiar to some varieties), can be considered suitable for open-air cultivation in this country; but on this point, as well as on many others in connection with Figs, we have yet much to learn.—A. F. Barron (*Read before the Royal Horticultural Society.*)

CULTURE OF MARÉCHAL NIEL ROSE.

Your correspondent, "A Subscriber," is quite right in his observation that the blooms of the Maréchal Niel exhibited at shows are selections from large stocks. You do not see the failures but the successes. It is a Tea-Noisette in family, but not in character, as a Noisette means a cluster Rose. It was derived from Isabella Gray, which sprung from the Cloth of Gold. The latter in my garden (four plants in the open air), is a rampant grower with plenty of foliage. I think of budding the Marshal on the new powerful shoots of Cloth of Gold. The Tea and Tea-Noisette Roses succeed best under glass. They like rich Barley and Turnip soil, with free drainage, intense heat, plenty of water, and little pruning.

As your correspondent only keeps a few yellow Roses, let him procure Gloire de Dijon and Triomphe de Rennes. For a standard, I specially recommend Céline Forestier. I have a most elegant standard of it here, given to me by the Rev. S. B. Hole. It blooms better as a standard worked on a Briar, than on its own roots, or on a Manetti stock.

Triomphe de Rennes and Gloire de Dijon will do well on a Briar, or on their own roots, or on the Manetti, and in the open border, or against a south or south-east wall.

To fill a large space of south wall, no yellow Rose will excel Solfaterre. The best Maréchal Niel I know is in front of the wall of a vinery. Mine are best in that situation.—W. F. Radclyffe.

ASPECTS OF SPRING GARDENING.—No. 4.

(*Concluded from page 56.*)

Resuming my notes on Nuneham Park, and coming away from that part called "Mason's Garden," a pleasant winding walk by tall banks of shrubbery, and ending in an ascending flight of steps, leads to the north terrace garden, and here an entirely new scene opens to the view. In our floricultural progress up to this point we have been treading a pleasant flowery ravine, hidden between two huge walls of trees on either side, with a foreground of shrubbery and flower beds. So calm and peaceful is it, so sublime and beautiful, and so solemnly still, that it might be likened to a vast open temple, wherein some of the most lovely forms in nature wait upon the Beneficent Hand that gave them being, and hath so lavishly "decked the earth with trees, brightened it with flowers, and gladdened it with the sun." On the emerald floor of this temple are gathered innumerable types, both of leaf and blossom, varied in form and hue, but unchanged in their one simple act of devotion; there

> "The flowers come forth like voices sent from some sweet land of love,
> And breathe of some more glorious world, like the returning dove."

And to fill up the outline of the simile—

> "while airily aloft
> The trees their cool green feathery foliage droop,
> Scarce stirring in the breath of fair Spring's morn—
> Like verdant banks on the broad stream of life."

But on the north-terrace garden a broad expanse of open country bursts into view; below, in a grand valley,

> "Clear serpentining Isis smoothly glides,
> Full-flowing in the distance."

Beyond, Abingdon, and a vast tract of country in the distance on hill sides rising up, as it were, to the sky. On the right the eye catches in the distance a glimpse of the classic halls of Oxford; on the left a lengthened and commanding rampart of woodland shuts out the park from view, screens the vale below, and affords a kind of broad ledge, whereon runs that grand walk of a mile in length, regarded as one of the masterpieces of the great landscape gardener, "Capability" Brown. The north terrace garden is inlaid on gravel; there is no grassy turf to vary the flowers; to see that, one must look over the balustrading on to the park below.

The ground plan of this terrace garden forms a kind of an irregular triangle, and comprises twenty-nine beds of various shapes—some large and others small, and so disposed as to fit into the shape of the garden, which is bounded on two sides by the north wing of the mansion, leaving the other two sides completely exposed. In the centres of five of the beds were stone vases set on pedestals, each vase filled with the charming Dielytra spectabilis. Looking over these beds, the most gorgeous were two of circular shape, having in the centre Young's Blood Wallflower, a very fine dark strain, yielding grand masses of colour, and much esteemed by Mr. Stewart, the Wallflower being surrounded with the blue Myosotis, and edged with the golden-flowered Alyssum saxatile. Another bed was of an oblong shape, the centre being filled with Silene pendula, and edged with Viola cornuta. Phlox frondosa, mingled with the common blue Venus' Looking-glass, made a pretty bed, though the blue form of Campanula pentagonia would be more effective in this relation, as it would yield larger flowers of the same hue, and a corresponding extent of or mass of colouring. Some outside slips of beds, actually describing a very important flank movement in this floricultural review, filled with the yellow Cliveden Pansy, with white Myosotis, with Phlox frondosa, with the Cliveden blue Pansy, and with both

the blue and white forms of Campanula pentagonia, gave charming masses of colour, varying the mixed character of the larger beds. Other forms of the arrangement of plants and colours were—a centre of Alyssum saxatile edged with blue Myosotis, dark Wallflowers edged with white Myosotis, white Cliveden Pansies mingled with double white Primroses, and edged with Phlox frondosa—a very pretty bed; and four circular beds raised in stone, in each of which the centres were composed of Leptosiphon densiflorus, mingled with Calandrinia speciosa, with here and there a few Cliveden white Pansies mingled with them, two of these beds being edged with Aubrietia deltoidea purpurea, and two with the variegated Arabis albida.

On the west terrace there is no flower garden, but it is flanked by a balustrading of pillared stone, ornamented with fine vases at intervals, the terrace affording a broad unobstructed promenade. From this point the terrace takes a turn to the left by an alcove, with trellis-work seats resting against the house, and covered with Roses, Jasmines, the grand Clematis lanuginosa, and other climbing plants. A fine Wistaria sinensis, thickly studded with pale purple racemes of flowers, is here seen growing against what is termed the corridor—a limb of the mansion connecting the more modern southern wing of the building with the old centre; and then into the south terrace.

It was here the glories of the system of spring gardening at Nuneham appeared to culminate, for a most charming sight bursts on the view, showing a symmetrical arrangement of twenty-eight beds of spring-flowering plants in two parallel divisions, with a broad gravel walk dividing them, like two hostile armies drawn up in array of battle, or like the recoil of a wave. Each flower bed on the one side has its counterpart on the other, as like itself in design, careful planting, and keeping as can be. Six vases on pedestals occupy positions on either side of the walk, two at each end, and two centrally, and green glazed earthenware settees take positions along the walk.

Starting from the north end of the terrace, a bed of Limnanthes Douglasii opens the floral display on either side. Granting that this valuable spring-flowering annual, so hardy as to be able to withstand the rigours of all weathers, has a somewhat weedy appearance when in flower, it must yet be borne in mind that at every stage of growth it does good service during the winter months, for previous to its making its flowering growth it takes the form of charming tufts of vivid green, especially after a fall of snow has lain upon it for a few days. Then come two show beds of Young's Blood Wallflower, the beds being edged with Arabis albida variegata. It was singular to note how the cold easterly winds had altogether changed the colour of the Wallflowers, turning them from a rich dark colour to a pure yellow, pencilled with dark, though the flowers had opened of their usual dark hue. All the spring flowers were of this rich dark hue also, but they were rapidly changing as they became exposed to the chilling effects of the wind. Then came beds that were very bright and effective, being filled with Tournesol and Rex Rubrorum double Tulips mingled together; then beds of blue Venus' Looking-glass, edged with that most useful of all spring-flowering plants, the charming golden-blotched Bellis aucubæfolia. This has not been used so largely at Nuneham this season as is generally seen, the unusual drought of last year having destroyed so many of Mr. Stewart's plants. Then came beds of Alyssum saxatile, edged with the blue Forget-me-not, the former a glowing mass of colour. Then beds of Collinsia bicolor, edged with Bellis aucubæfolia, not a good combination in so far as symmetry of growth is concerned, the former being too tall, and quite overshadowing the Daisy. Then beds with centres of blue Forget-me-not, edged with Silene pendula alba, and further on this order of colours was reversed, for in the last case the white Forget-me-not formed the centre, edged with the pink Silene pendula. Between these, however, came some grand and sunny beds of Young's Wallflower, edged with the blue Forget-me-not—striking masses of colour. Then beds of the white La Candeur and crimson Rex Rubrorum double Tulips, mingled with the blue Forget-me-not, and edged with Bellis aucubæfolia. Next these, and forming the terminations of the divisions of the beds on either side, were masses of Limnanthes Douglasii, corresponding with those at the outset. From this point of the south terrace garden a flight of stone steps leads down to the pleasure grounds—a kind of ante-chamber to the grand woodland walks and charming openings of scenic effect designed by Brown. Standing at the foot of these steps, and looking back on the masses of colouring seen in this garden, was to survey a brilliant floral picture limned by a master hand—a picture that could be lingered over with pure appreciation, and be remembered with unalloyed delight.

But as all preachers apply their subject at the close of their discourse, so must I follow with an application at this point. There is, after all, a simplicity about the form spring gardening has assumed in these days—a simplicity that brings some features of its disposition within the reach of the capacities and circumstances of all having space to apply them. Simple hardy annuals are the main instruments by which spring gardeners work out such important results. Collinsias, Nemophilas, Forget-me-nots, Wallflowers, Limnanthes, and others, sown in August in out-of-the-way patches, and only to be lifted into their blooming quarters when

> "The dry, crisp leaves are ankle deep
> In woodland ways;
> And wild winds, shrieking from polar seas,
> Cry to the lorn and withering trees
> Of coming winter days;—"

and early frosts have destroyed the last remnant of the summer display. Such things as Daisies, of all colours (for all are extremely useful), Polyanthuses, Hepaticas, and all else of a character propagated by root-division, can be lifted at the time the annuals are planted, divided at the roots, and planted in their blooming quarters. The variegated Arabis, Alyssum saxatile, Phlox frondosa, Iberis sempervirens, &c., can all be propagated by cuttings. A few bulbs go a great way in a spring garden, and if they are carefully lifted at the time the spring-flowering plants are removed to make room for the summer bedding stock, and replanted in a shady place in some light sandy soil, and so left to ripen, they can be made of good service for successive seasons; besides, they propagate themselves by forming offsets. Another point to be urged, is its comparative inexpensiveness. This will be seen from the remarks made in regard to its simplicity. It is, therefore, within the reach of all, as the outlay in starting is comparatively small. Most important of all, as a principle of application, is a "reserve garden," to serve as a kind of nursery during the summer months. A small piece of ground will accommodate a great many plants, as they can be placed closely together, and cuttings occupy but little space. In most gardens there is a small piece of ground which can be used for this purpose, even those with limited means in this respect can work wonders, if they are determined to succeed. Some knowledge of the plants used is essential, and if this is possessed only in part, it is soon augmented by the results of experience—one of the best teachers in the flower garden. "If it were not for my Orchids," says Mr. Jerningham, in "Birds of Prey," "I think I should go melancholy mad; but for the cultivator of Orchids there can be no such thing as satiety, until all the forests on the shores of the Amazon have been rifled by exploring botanists." In like manner, I, too, should be inexpressibly grieved were there no spring-blooming plants to fill up the dreary void in my flower garden between September and May. With these I bridge the chasm that separates decaying autumn from budding spring, and sink the two in a common bond of floral service.

Thomson, in his poem on the seasons, sings—

> "See, Winter comes to rule the varied year,
> Sullen and sad, with all his rising train—
> Vapours, and clouds, and storms."

But the face of nature in so far as it is reflected in our flower gardens, need not be "sullen and sad" when winter comes, for our gardens can be made to smile joyously into its stern face, and transmute some of its dreariest aspects into scenes that shall recall gleams of the lights that have gone out with the past summer; or, better still, be prophetic of their advent once again, when the icy bands of winter shall be removed by the warmth of the gentler and reviving spring, from the fettered, but not vanquished hands of Nature.—Via.

SCALDING OF GRAPES.

I noticed in the Journal of July 29th, some remarks concerning scalding in the berries of Lady Downe's Grape. The same Grape in a vinery here has had the same fault, both in the last and present season; the berries are attacked as soon as stoning is finished, and they are liable to be injured until they commence to colour. The fault is not in the glass, as the berries are injured where the bunches are amply protected from the rays of the sun by the foliage, although not to the

same extent as they were on one or two bunches on which the sun shone unprotected by any screen during two hours each day. The only way to avert the evil is to keep the house as cool as possible during the day, let all the ventilators and doors be thrown open until the sun is off the house in the afternoon, and if the vinery is sufficiently provided with ventilators very little damage will be done. No other Grape, now or old, that I am acquainted with has ever suffered with me in the same manner. Mrs. Pince's Black Muscat is not injured in the least. I have this variety grafted on Lady Downe's, and the thickness and luxuriant growth of the cane is remarkable; on its own roots it does not seem a strong-growing variety.

I hope these few remarks may be of use to your correspondent "Oakwood," and others who may be in a like case.—James Douglas.

PAPERS READ AT THE HORTICULTURAL CONGRESS AT MANCHESTER.

The Council of the Royal Horticultural Society have placed in our hands for publication the papers that were read at the meetings of the Society held at Manchester on the 21st and 22nd of July. The meetings at which these papers were read were what were announced as the "Horticultural Congress," but which partook of nothing of the character of a congress, and therefore failed, as we anticipated, to carry out the idea of what was foreshadowed in the programme and announcements.

The intention of holding these meetings, and it was a laudable one, was to take advantage of the presence of the large body of horticulturists who would be attracted to Manchester by the Show of the Royal Horticultural Society, and to elicit from them their practical experience on subjects which were brought before them by gentlemen competent to do so, in the form of essays. But instead of deliberation, discussion, and resolution, which are the essentials of a congress, there was nothing but the bare reading of the papers, which we are now about to publish in our pages.

The idea of a congress was a good one, and if it had been carried out its meetings would not only have been fraught with much interest to those who were present, but many disputed questions might have been settled had those who entered the lists to discuss them have possessed the knowledge and ability to deal exhaustively with the subjects. But the idea was not carried out, and those who attended to hear the papers read were either unable, or what is more probable, unwilling to discuss at such a time and in so public a manner questions which they knew they could deal with in far more comfort and to much greater advantage in the public prints.

It is a consideration, therefore, whether it is worth while to repeat these meetings on the occasion of the future provincial Shows of the Royal Horticultural Society, the result being so incomparably short of the means used to attain it. There is first of all the room or tent in which to hold the meetings, and the attendant expenses. There is the tax on those few members of Council who go down to these Shows, and whose offices are for the time anything but sinecures, to be present to countenance the proceedings. There is the tax also on the authors of the papers, who are at the expense of travelling far distances to read them, and then, without any consideration, to surrender possession of them—a tax of which we have had more than one complaint. And there is the tax on the public—not a very numerous body certainly in the present instance, who, ignorant that they would have an opportunity of reading the papers in comfort for themselves in our pages, listened to them with commendable patience in a small stuffy tent under the rays of a broiling July sun. Unless the perfect idea of a congress can be carried out, we do not see what good can arise from a few gentlemen meeting together merely to read a few papers on topics which are ordinary subjects of treatment in the weekly horticultural journals. As a congress the affair was a failure, and if these meetings are to be repeated, let them have a fitting designation; but let them not in future be dignified by the name of that which they in practice fail to realise.

WHAT SOIL IS BEST SUITED FOR THE PRODUCTION OF GRAPES?

A question continually asked by amateurs and others is, "What kind of soil should I use in making my Vine border?"—"Choose," says the stereotyped reply, "turfy loam from a pasture field." So far the answer is correct; but the geological formation is never named, whether calcareous, silicious, or igneous, assuming that quality in this particular requires no consideration.

I admit that there is some difficulty to secure soil in a free state, as the different formations very often pass into each other. For instance, we have the calcareous sandstone soil when the former predominates over the latter, and again the silicious limestone when the finely divided particles preponderate.

However lightly some cultivators may estimate the propriety of providing certain descriptions of soil for the growth of certain classes of plants, our everyday experience demonstrates that the different constituents have separate duties to perform in the vegetable economy, whether the action is chemical or mechanical; and further, we cannot controvert the fact that the duration of life in plants, and the quality of the fruit, are true expressions of the soil on which they grow. Analogy is certainly not an accurate system of reasoning, but in the present case may be of some assistance. Within the area of the boulder clay it has been found that the best race of men is produced, also the best cattle, and that the death rate is lower. If we accept this statement we need not hesitate to admit the validity of the preceding conclusions.

In relation to, and in support of these preliminaries, I now pass on to deal with what may be to some a more practical part of the subject,—one which has for years past given me considerable anxiety, and produced sometimes strong feelings of self-reproach. The case to which I wish to draw attention refers to the unsatisfactory state of the Grape crops at Tortworth.

Let me notice first that the soil of which our Vine borders are made holds a large proportion of magnesian lime; one vinery is planted exclusively with the White Muscat of Alexandria, and although eighteen years old, its strength has not greatly diminished. There has never been cause to complain of sterility, the show of fruit has been invariably good, even as many as four large bunches are generally produced from a single eye. The berries always set freely, and during the first stage grew to a large size, leading to the supposition that when fully ripe their quality would meet the approbation of the most fastidious. The very reverse of this was the case; when they had finished stoning there was no further increase of flesh, a decrease was more frequently preceptible; the skin began to shrivel and turn leathery; there was also a deficiency of saccharine matter, and of that peculiar aroma the exclusive property of the Muscat.

How to account for so decided and so violent a departure from the ordinary course eluded every attempt, and my conclusions never rose above mere speculation. Had this occurrence happened occasionally, there would have been sufficient room to suppose that my practice had been one unvarying course of mismanagement; but there was no cause for any suspicion of the kind, as the same conditions were closely adhered to which had heretofore been attended with some amount of success. The border of an adjoining house was made of soil in every way similar, and was planted with Vines of the Black Hamburgh, Foster's White Seedling, Buckland Sweetwater, and Golden Hamburgh. We have here a slight improvement in the produce of the first two varieties, but even then the best bunches were hardly second-rate. The latter were always to some extent unproductive, and what did make their appearance were straggly in the bunch, and deficient in berries.

Interposition very frequently alters the whole course of events, and brings about a change which the agent had not anticipated, and it so happened with me. We found it necessary about fourteen years ago to renew an old Vine border. I had no choice of soil; so whatever benefits were then produced did not depend on any foreknowledge of mine; they were purely the result of unforeseen circumstances. I can best describe the quality of the soil by saying that it belonged to the old red sandstone formation, contained not a particle of lime, and was composed of silex, alumina, and organic matter derived from decayed herbage. At the time the border was made no manure was added, nor has any been since applied, except a small portion mixed with turfy loam of the same description as an occasional surface-dressing. The varieties were the same as in the preceding house, which gave me an opportunity of estimating correctly the Grape-producing properties of the two kinds of soil. I had not the slightest idea as to what would occur. I did not anticipate that results would differ materially from what I had already experienced. But when the Vines began to bear, the improved quality of the fruit certainly took me by surprise,—more particularly as regards the Golden Hamburgh, being perhaps a little more difficult to manage than any of the other varieties. Many of the bunches exceeded 4 lbs. in weight, and the berries 4 inches in circumference.

I do not offer these statements on the supposition that they represent more than what is to be seen daily; they are merely given to

mark the distinction between the past and the present, or, in other words, between the expressions given by the two kinds of soil. We have here a change, resistance has given way, circumstances are completely altered, an effect of a very decided character has been produced. Now the question arises, and often repeats itself, "What is the cause?" Not by any possibility can it exist in the general management, as there has been no variation, neither has any occurred in the arrangement of the border materials, the same principle having been adopted throughout.

I now feel satisfied I cannot evade the conclusion, the fact is forced upon me, that the caustic property of the lime has worked all the mischief; and that the nearer it approaches to a state of carbonate, the more fatal the effect. Magnesian lime is the worst we have to deal with, as it retains its causticity longer than any other kind.

Having succeeded in my exertions so far, I next applied silicious soil mixed with a third part of manure, for the growth of our pot Grapes. Without entering into minute details, which are the property of every gardener, it will be sufficient to notice that the quality of the fruit was equally satisfactory, and as a guarantee I may note that a Vine of the Alicante, one year from a single eye, matured 18 lbs. of excellent Grapes. These results encouraged me to proceed a step further; I had the earth removed a foot deep from the borders made of calcareous soil, and replaced by silicious soil, on the supposition that it might to some extent act as an improver. Although the roots worked amongst it freely, and have been doing so for some years past, I have not been able to discover that it has produced any advantage. There is one caution to be observed in the selection of silicious soil—namely, that it is frequently to be met with, and sometimes to a considerable extent, mixed with oxide of iron, which should be avoided. Whatever opinions are held or may be formed by gardeners on this subject, the red sandstone soil with me, for the growth of the Grape Vine, has long become a settled article of belief. In making this declaration, I do not exclude soil from other geological formations, I only offer a protest against the presence of calcareous matter.

A writer of considerable reputation has strongly recommended soil from igneous rocks, but of this I have had no experience. Nothing, perhaps, stimulates inquiry, and gives wings to thought so much as to feel ourselves probed by the sting of defeat; perception becomes more penetrating, and the range of ideas more extensive. So, in debating this matter, it occurred to me that I had always seen Grapes, produced from the limestone, of a very inferior quality, and from the chalk the sample was even worse. Without penetrating into the cause further than mere external observation, I without hesitation placed the entire blame on the shoulders of the gardener. But I have lived long enough to admit that I was wrong, and to withdraw so false a charge.

There may be few, still there are some, gardeners who believe that a successful career of Grape culture depends upon the observance of a system of set rules more than anything else, and when these fail to produce what was anticipated, what do they do next? Why, submissively wait on Providence to help them.

What is generally understood as mere practice has long ago yielded all the sound information it ever had or can possess. Shall we then continue to submit to the dictation of what is effete and powerless? Shall we perpetrate the folly of threshing the same straw over and over again, and winnowing the same old chaff? No! by no means, if we are to make progress. We must shunt out of so narrow a groove, we must take hold of principles, and learn from them how to make a successful application of that description of food best adapted to certain classes, or to individual plants. At the present time the mode in which many inorganic substances act is very imperfectly understood, and must of necessity remain so until the office they perform in nutrition is clearly ascertained.

There is no reason why we should continue to remain uninformed on this point any more than on the subject of those complex matters that go to build up the animal system. For this purpose analytical tables have been prepared, which direct us to select those aliments which furnish muscle, bone, and blood, or indeed all that is necessary to build up and sustain whatever belongs to the composition of the living body. And again, let us observe with what exactitude the chemist prepares his medicines, and how, by an accurate knowledge of their action upon different parts and organs of the human system, the skilled physician is enabled, either to cure disease or lessen the pangs of suffering. The question may be asked and answered in this way:—Is the science of horticulture to be kept below its legitimate status—are we to plod on as heretofore in a hazy atmosphere—are we to allow our operations to be governed by something little short of haphazard? Certainly not; our profession is as much entitled to rank as highly as any other department in science. We ought to be able to exercise as much control over the vegetable kingdom as the physician does over the animal kingdom.

I do not say that gardeners must of necessity become learned chemists, or vegetable physiologists, the bare supposition would be an absurdity. What we do want is a recognised authority to whom we may apply to have our soil analysed at a moderate charge, which would be a practical benefit to the entire community.

To show that soil possesses a greater influence than we are at all times willing to admit, we shall suppose a case, and the supposition is quite correct—viz, that one, two, three, or more of our best Grape-growers, persons whose success has been uniform on some particular kind of soil, we may name the purely silicious, were removed to the calcareous districts, it will be found that the quality of their produce will differ widely, even although all other circumstances are the same. I would then suggest, that the soil on which first-class Grapes are grown should be analysed and the result published. This would inform us correctly of the properties that operate so favourably, and be a guide to others while making a similar selection. Some may question my statement. Still, I hold the fact firmly, that our achievements, no matter how great or small, depend more on the quality of the soil we use than on anything else, and consequently place every intelligent gardener much on the same level.

It would be both interesting and exceedingly useful, did the nature of this discussion and the limits assigned me permit, to give a description of those trees and plants that require time for the proper maturation of their fruit, and those to which it is injurious; success and failure have more to do with these points than we are at all times aware of.

The office performed by inorganic nature in the vegetable system has never been clearly ascertained, at least it has never been fully explained, but has given rise to vague speculations that confuse rather than instruct, and breed a vast amount of contention.

In conclusion, I would state how desirous I am to see the time when science and practice shall mingle together, and not till then can we acquire the key that opens the door of legitimate progression. However much we may neglect the observance of the fact, whether through ignorance or from any other cause, an immutable law reigns, which governs animated as well as inorganic substances. It pervades the world—there is no place where its power does not act—there is nothing beyond the reach of its influence.—Alexander Cramb, *Tortworth Court.*

ON THE PRUNING OF FRUIT TREES AS AFFECTED BY SOIL, CLIMATE, STOCKS, &c.

Fruit trees are, it is to be presumed, mainly cultivated for the sake of their fruit, consequently the chief object of the cultivator should be directed to its production; and much may be accomplished towards this end by a rational system of pruning

The judicious pruning or non-pruning of fruit trees is an all-important question, far more important than that of training, with which it is frequently confounded. Training is the producing of form—an ornamental part of the business, and is at times rather antagonistic to producing fruit. But pruning, whilst necessary for training, is chiefly performed for the sake of securing fruit. To prune a fruit tree is a very different thing from pruning any other sort of tree, inasmuch as the production of fruit is much more difficult than that of timber, or merely ornamental form. It is, indeed, easy to grow a tree and prune it so that it may assume any desired form or size. This is merely a question of time, and of the careful adherence to some given rules or pre-arranged plan; but to make that tree produce good fruit in large quantity, and of good quality, requires the exercise of much more skill and knowledge. To do this, however, is the office of the pruner, and by proceeding judiciously he may accomplish it.

To lay down any definite rules for guidance in fruit-tree pruning, beyond the broadest general principles, is impossible, for in practice we have so many variations of soil, climate, subjects, and even stocks, to deal with, all exerting considerable influence, that no given rules can be strictly followed. That which may be proper or advantageous for trees on one soil, situation, district, &c., may in another case be found totally impracticable. Further, also, a great deal depends on the time of pruning, and the manner of the operation. According to the amount of foliage duly exposed and properly developed, the growth of the tree advances; therefore, although the reduction of any part of a tree on which leaves are produced may diminish the rate of increase on the plant generally, yet through its removal the parts left increase more rapidly, in consequence of having a greater supply of sap at their disposal, and of their leaves being more fully exposed to the influence of light. Therefore to prune judiciously is not only advantageous, but in fruit culture it is indispensable.

To prune a tree is to cut off a portion of its stem, or parts of its branches, and the object to be attained is the regulation of the vegetation of the plant. The immediate effect (it may be repeated) of pruning, or the cutting-off of any portion of a plant, is to cause a greater supply of sap to flow towards the parts which are left. Thus, if a tree is growing vigorously and making strong unfruitful shoots, the effect of pruning it back severely in winter is to increase its vigour instead of weakening the tree. All winter pruning, or pruning after active vegetation has ceased, results in producing greater vigour in a plant; therefore a vigorous healthy-growing tree requires less pruning than a weakly-growing one

A special point to be aimed at in fruit culture is equality of growth, and thereby uniformity of action, throughout all the component parts of the tree. The most unfruitful of all trees are those in which one portion is allowed to have a great ascendancy over the others. The stronger portions of these have then to be repressed, and the weaker portions encouraged, which will promote uniformity of growth. Excessive vigour is, however, undesirable, as trees in that condition bear but a small quantity of fruit; yet it is possible for a tree to be too weak, and to produce too many small fruits, as well as to be too vigorous and unfruitful.

There may be said to be two distinct styles of pruning—viz., market garden or orchard pruning, and gentleman's garden or trained-tree pruning. The one is necessarily very different from the other. In

the former case the trees are allowed to retain much more of their natural character; they are pruned almost entirely for fruit, form or appearance being in a great measure ignored. In the latter, while fruit-bearing is one main object, yet with this is combined the formation or retention of some particular form. Which of the two, then, is the more productive or profitable? which of the two is the more to be recommended? Or is it possible to apply the treatment as regards pruning that is necessary for the one to the case of the other, or to produce the same results on each subject alike in different soils, situations, &c., without having regard to the altered circumstances in which they are placed? It may be possible, but it is scarcely practicable to do so, and in many cases the attempt will result in an entire failure; the trees, as already stated, may be formed, yet the fruit for which they are grown will be wanting. These remarks apply more especially, yet not exclusively, to formally trained trees.

If we take a glance at the natural tree vegetation of the country, we shall find that in one locality the trees are of a dwarf stunted character, and perhaps very fertile; while in another they are rampant and vigorous. In the one case we have probably poor sandy soil and an exposed situation, and in the other deep alluvial loam and comparative shelter. Good fruit may be produced in each situation, yet under very different conditions. Here, then, is Nature teaching us, and her general laws we must obey; for though we cannot alter this natural order of things, much may be accomplished by skill in moulding the one to a similarity of the other. The light soil may be enriched, the strong loam impoverished, shelter may be procured, &c.; but these can only be done in a very limited way. Unless, however, something of the sort be done, the growth of the trees in the two instances will be very different; and in order to induce an equal amount of fruitfulness, the treatment of the trees as regards pruning will require to be very different also.

Since viewing the extensive experiments on agricultural produce of Mr. Lawes and Dr. Gilbert, at Rothamsted, with different manures, and the wonderful influences effected by these manures on different plants as regards their tendency to induce a disposition to run to seed, and to favour early maturation, it has occurred to me that perhaps something in this way might be accomplished with fruit trees by the application of some special manures, which, as in the case of the mixed mineral manures on grasses, would give a tendency more towards fruit-production than to leaf-growth. There may be a manure for fruit trees, which is capable of utilising the existing and necessary portions of the soil, and concentrating all the energies of the plant towards the production of fruit; and if so, how valuable it would be!

Again, climate greatly influences the growth of trees, and in some respects its effect is similar to that of the soil. Thus, a damp climate, such as that in the south-west of England counteracts the effects of a dry soil, assimilating the results to those afforded by a deep rich soil in a dry climate. In a damp climate trees grow much more luxuriantly as a rule than in a dry one, and as luxuriance of growth is unfavourable to fruit-bearing, our treatment of the trees must again be modified to suit the altered conditions. In the orchards of Devonshire, and other parts with damp climates, there is a remarkably natural check put upon the growth of the trees, which would otherwise be over-luxuriant and unfruitful—namely, the growth of Mosses and Lichens on their trunks and branches, caused, no doubt, by the continued dampness. The presence of these epiphytes serves, however, in my opinion, as a beneficent check upon over-luxuriance, and thereby induces greater fertility than would otherwise be obtained. Here, then, is Nature repressing vigour more effectually than we can do by the employment of any artificial means. It being, then, as yet impossible to alter soils or climate to any great extent, we must perforce, if the greatest success be desired, cultivate only those trees which are most suitable, and that after the manner most in accordance with their natural tendency. In short, in a locality where trees naturally grow but slowly, dwarf or miniature fruit-tree culture will be the most advantageous; and where trees naturally grow luxuriantly they must be allowed to do so, the modern dwarf, closely-pinched fruit trees being for the most part unattainable.

There is, however, yet left for consideration the important subject of the stocks whereon we may graft our fruit trees. The influence of the stock is in many ways marvellous. It is as yet a subject but very imperfectly understood, especially by fruit-growers themselves, whom it concerns most intimately. It might be given as a proverb, "According as the stock is so will he the result." We have not only stocks which impart great vigour to the plant, and the reverse—those which check luxuriance and induce greater fertility, precocity, and a tendency to maturation—but we can also select stocks which enable us to cultivate fruits with an almost equal amount of success on damp clayey soils, as on dry sandy loams. It is also worthy of experiment on a somewhat extended scale, to find out whether it is not possible to cultivate fruits successfully in otherwise uncongenial districts by grafting and using plants indigenous to the district, as stocks, such as the Pear on the Mountain Ash, and on the different species of Thorns, which are in general common enough. That would be utilising the natural vegetation of the country.

It may be well here to notice briefly some of the principal stocks used for our fruit trees, and to state the conditions under which, as well as the purpose for which, they can be most advantageously employed.

Apples.—1. There is the Crab or free stock, most suitable for large standard trees, and totally unfit for dwarf ones. 2. The French Paradise, which is eminently qualified for producing dwarf fertile trees, and which succeeds best on damp, clayey soils, its roots feeding near the surface. 3. English Paradise, a moderately vigorous-growing stock. 4. The Nonsuch English Paradise of Mr. Rivers, which is similar in its effect to that of the French Paradise, producing vigorous but fruitful little trees. It however succeeds well on dry soils, which the French Paradise does not.

Pears.—1. The Pear, or free stock, which, like the Crab, is again only suited for large trees, excepting in dry soils, in which case, on account of the roots striking deeply for sustenance, it is the most to be recommended. 2. The Quince, which is admirably suited for cultivation in damp soils, through its roots feeding near the surface, is entirely unsuited for forming very large trees on dry soils. Its great recommendation is in its dwarfing tendency and its exceeding fertility. Pears may be grafted on many other stocks, such as all the species of Cratægus, Mountain Ash, Cotoneaster, &c.

Plums.—These are not much influenced by the stock, excepting it be the Damas Noir, which tends to earlier fertility.

Cherries.—1. We have the wild Cherry, which is adapted for large trees. 2. The Mahaleb, the most suitable for dwarf-fruiting plants. Plums may also be grafted on Cherries, and *vice versâ*. Beyond the fact of its accomplishment, however, I can state nothing, as the ultimate results are not known.

By way of illustration, we may admire the successful results attained by Mr. Rivers, in his magnificent culture at Sawbridgeworth, with myriads of pretty miniature bushes, pyramidal and cordon trees, all densely laden with fruit; and we may further be enlightened as to the practice pursued to produce such success, and become in consequence impressed with its desirability, and induced to go and try to do likewise—to have our fruit trees all grown in the same miniature style, &c. We see the results, and seize the idea, but most likely forget the conditions, or the natural or other advantages enjoyed by them, through which they have so easily attained their present fruitful state. The natural tendency of tree vegetation in the soils of Sawbridgeworth is towards early fruiting. There is, indeed, considerable variation of soil even in these nurseries—from strong Wheat land to lightish sand; yet throughout nearly the whole extent there is a great deal of calcareous matter, which it will be found, wherever present, is the most favourable of all for fruit culture. It is greatly to the predominance of this chalky matter in the soil, though partly to its exposed situation, and also to the use of suitable stocks which give a dwarfing tendency, yet, most of all, to Mr. Rivers' skill in taking advantage of all this, that we are to attribute his immense success in the culture of miniature fruit trees. To illustrate still further, go to the neighbourhood of Paris, where in fruit culture results are attained nearly similar to those of Mr. Rivers. Fruits and fruit trees, it is well known, succeed there admirably, and the soil is very similar to that so general at Sawbridgeworth. Around Paris the climate influences and benefits the condition of the trees and fruits to a considerable extent, yet otherwise the results are as nearly as possible the same.

Trees in the two instances grow but slowly, yet sturdily, and make no rampant watery unfruitful shoots; these are, on the contrary, sturdy, short-jointed, and well-supplied with fruit buds. Indeed, the difficulty of their having too much of a fruiting tendency occurs at times, the trees being thereby soon exhausted, and the fruit rendered worthless. It is desirable at all times that fruiting trees should produce a certain quantity of young shoots, as on the influence of the leaves so produced and on the action thereby infused into the plant, depends chiefly the quality of the fruit. Hence to induce short formation, although there may be little to prune, yet the pruning-knife may be used to great advantage, and the shoots cut closer back. In fact, the trees may be kept in smaller compass than that which would be prudent to adopt in the case of trees growing very vigorously. The cultivation of miniature fruit trees, trees planted at 4 feet apart, in such soils and conditions, is highly commendable. It would, indeed, prove the most profitable; as although they might be allowed to attain considerable size, it would be many years, owing to their slow rate of growth, ere the ground could be otherwise fully occupied, or turned to the best account for fruit culture.

To reverse the picture, however, let us visit the rich valley of the Thames, with its deep alluvial loam, and look at the fruit culture in some of the market gardens—for example, that of Mr. Dancer, at Chiswick. Here there is also fruit in abundance, and of the very finest quality. Here, however, the trees instead of being dwarf and fruitful, are large, rampant, and vigorous; and although while in a young state they produce but little fruit, still as they attain age, if not over-pruned, fruit is produced in immense quantities.

In the one case, winter pruning—close pruning, is necessary to induce greater vigour, and prevent overfertility and weakness—(*i. e.*, assuming the stocks, &c., used in each locality to be the same); and in the other, the object of the pruner is to reduce luxuriance, and this is best effected by non-pruning, or at most, by the thinning-out of the shoots and branches where crowded, so as to expose the remaining ones more freely to the influence of light, leaving the strong-growing young shoots at almost their entire length, which the next season produce a less vigorous growth, and as a consequence become more fertile, on account of the forces of the plant not being concentrated on a few buds, but being required to spend itself over many. In short, in the one case miniature fruit-tree growing is advantageous and practicable, simply because the trees are not inclined naturally to grow larger, and in the

other it is almost impossible, because the trees naturally grow too luxuriantly.

Excessive vigour may, however, be considerably repressed, and fruitfulness may be induced, by judicious summer pinching of the growing shoots, and also to a great extent by root-pruning. The first summer pinching is of paramount importance. It is most easily accomplished on the naturally fertile trees, yet it is most required on the most luxuriant. By constant application a great deal may be accomplished. It is an operation rendered absolutely necessary in all formal styles of training, and in the culture of miniature trees. The leaves of a plant are almost its very life; they are its breathing organs. Leaves elaborate the sap which is drawn from the roots, and return it into the stem to form woody fibre, so that the pinching or the taking away of any portion of its leaves arrests the flow of sap in that direction, and directs it towards the parts which are left. Thus, therefore, by stopping the stronger-growing portions—those on the upper parts of the tree, which are in advance of the lower or weaker portion—we equalise the flow of the sap, and cause a uniform action throughout. This stopping and checking of the shoot-growing propensities of the tree tends towards the formation of fruit buds, excepting in some cases—namely, in very rich soil, and where it is attempted to confine the energies of the tree within too narrow a limit. Under such circumstances the most incessant application will fail to produce fertility, but will result in the continued production of watery shoots, and a gradual weakening of the tree. In such cases root-pruning may in some instances be resorted to with advantage. Root-pruning in miniature fruit-tree culture is almost absolutely necessary to keep the trees within bounds in many soils. It should, however, only be appealed to as a last resource, after all other modes of checking vigour and inducing fertility have failed. Root-pruning tends too much to weaken the whole system of the tree, to take away the powers of the plant which are required for the support of what fruit there may be produced. It is not exactly a weakening of the entire system of the tree which is required, but a retention of all its powers, and a direction of those forces towards the production of fruit instead of that of shoots.

In concluding these remarks, I would recommend those who may be commencing fruit culture to take well into consideration the soil and situation of the place, and then the object, whether for the production of fruit simply, or for fruit combined with the formation of the trees after some particular form. Whatever may be the object, the condition of the soil should be considered, and the trees selected should be worked on stocks whose requirements can be best supplied by that soil, and by the mode of pruning and general cultivation adopted.—A. F. Barron, *Royal Horticultural Society, Chiswick.*

ON THE PROSPECTS OF HYBRIDISATION.

The object of the following remarks is to show how large a field is still open to cultarists in the matter of cross-breeding.

In order to see the extent and nature of this I will ask you to withdraw your attention to a considerable degree from the mere in-and-in breeding of a few favourite and already over-bred groups of garden plants, and to turn it to the higher object of originating new forms and qualities, by working with hitherto neglected or unthought-of subjects. Under this head I include:—

Genera hitherto unattempted.

True species unused, or insufficiently worked out.

Old garden plants, shrubs, or trees possessing high special qualities.

Variegated plants of all kinds to be used as the sires or male plants.

Other descriptions might be catalogued, but the above list would give us enough to do. I will not treat these cases separately, for they are much bound up with one another, but will take them as they happen to suit my present purpose, which is to say as much as I can in the shortest space of time.

Let us begin with ordinary cultivated things—the old familiar forms of the flower or kitchen garden, and note a few of our shortcomings. Enter genus Rosa:—The Rose has been said to be coming rapidly to a dead lock, so great has been its cultural improvement. But this improvement has run somewhat in a rut, hundreds and thousands of seedlings are raised annually, and yet we get little more than slightly improved forms of a few favourite types.

It is not my province here to point out the means of working to a given standard of perfection; this is the task of the skilled and practised craftsman whom we call the florist. The hybridist is the explorer and pioneer, after him comes the selective improver. I will not taunt my florist friends by saying, You have not yet produced a blue Rose; but let me just observe that the greater part of your show Roses have no scent, and many of them neither scent nor constitution. Your yellow Noisettes won't open; and of the perpetual, or Provence classes, you have no scented yellow Rose at all. Neither have you a white one fragrant and ever-blooming. Sweet odour, that complementary quality which, with other matchless attributes, makes the Rose of romance the real Rose of the poet and the lover, is absent. The scent of the Rose called Mademoiselle Bonnaire would never recall a memory. Again, you have no crimson Tea-scented Rose; you have no really good rampant or climbing perpetual Rose at all. Fellenberg and Eclair de Jupiter are far from perfection. Where is the very possible perpetual Pompone? With July we bid a long adieu, alas! to Rose de Meaux. Can these deficiencies be supplied? I think they can.

First let us lay the foundation for a white, by crossing together the white China and the white Unique Provence; also the whitest Tea, say Niphetos, with the same, and the old white Moss. For a blush-coloured race, take the fragrant old Maiden's Blush and Celeste, and cross with the pink-tinted Teas. For size and doubleness of flower, with fragrance, take Souvenir de la Malmaison and Comtesse Lacépède, and cross with White Provence and Moss with Maiden's Blush, even with the Common Moss and Cabbage Rose.

The production of a yellow will be more of a task. As seed-bearing parents let us take the old yellow China; it is still to be had, though very scarce; the yellowest Teas with the white China and old Sweet Double White. Cross these with the Austrian and Persian Briars. Also cross together the yellow Teas and China with the palest and clearest-coloured Provence kinds.

The Teas should be fruited in pots under glass. This will bring them into flower at the same time with the Austrian Briar. Moreover, they set their fruit freely when grown in this manner. For a high-coloured Tea Rose, the old crimson China Semperflorens would impart a large share of its colour to any of the true Teas, and the cross might be taken both ways.

It will probably take some generations to produce a good rich-coloured climber Fellenberg. Gloire de Rosomène and crimson China might be crossed together. Ruga, which seeds freely, might produce seedlings of higher colour and frequent-flowering habit by a cross with these last-named kinds, and for an experiment their pollen might be used to fertilise Coupe d'Hébé and Fulgens. The sluggishly-opening Tea Noisettes might be crossed with the old semi-double yellow China to produce an intermediate effect. I may here suggest that the noble old Noisette Grandiflora should make a fine seed-bearing parent when crossed with handsome vigorous Roses of almost any class, but especially the Provence breed.

Again, to originate new and hardy races there is sufficient evidence to prove the enormous advance frequently made by a first cross from a wild or natural species with the pollen of a cultivated one. I need only point here to Ruga and Maria Leonida, raised from two wild single species, by the pollen of the double Tea Roses; and the pollen of this exquisitely fragrant plant should be tried upon every natural species that can be procured.

I fear I have dwelt too long upon the Rose, but it was tempting—the Rose always is tempting. Moreover, it was a good subject for an endeavour to shadow forth my meaning to-day.

And now we will take a turn in the orchard. A few good Apples and Pears have been raised by definite and well-considered crosses, but many yet remain to be devised and carried out. One of the first, things that will occur to us, when once out of the old rut, is that we have scarcely any good summer Apples and Pears; none of any size, and none possessing the peculiar and higher qualities of the autumnal and winter kinds. Who has ever raised a seed of Citron des Carmes, or reared a brood of young Jargonelles, ennobled by the blood of Marie Louise, or other early autumn Pear? Who has ever collected, selected, and united in wedlock the pleasant but very improvable summer Apples? I think no one, as yet, not even the great Sultan of Sawbridgeworth. Is there any reason why the great size and hardy vigour of the Catillac and other culinary Peare should not be imparted to or shared by those sorts whose melting flesh and rich flavour fit them for the dessert table? Mr. Rivers has worked nobly at the stone fruits, and especially as regards the Peach, Nectarine, and Apricot groups; but there is yet a most interesting and important line of work left open to the horticulturist—viz., the breeding expressly for hardiness. Hardy Peaches and Apricots are known to exist. Let these be searched for, collected, and bred from; let them be sown, reared, and, if possible, fruited away from the sheltering wall. The long frosts of winter, and capricious climatic vicissitudes of spring, will of themselves form an effectual selective process. In all crossing experiments, hardiness should be kept prominently in view—hardiness of constitution generally, and hardiness to bear low temperature. It is common enough to hear it said, "Such a fruit is the king of its race, but it is so tender, or, it may be, such a bad bearer."

Should such things be when the cross-breeder has actually the power in his hands to combine given qualities and to impart deficient ones? Much attention has been given of late to the Plum, and we possess many fine sorts; but there still remains many a curious and haply profitable combination to be tried. The pretty and curious Cherry Plum has not yet been used as a parent. The hardy and prolific Damson would certainly produce valuable orchard sorts, if crossed with the Green Gage, Golden Drop, and other kinds possessing high quality and marked character. The common Bullace is a less promising subject, but it is in itself quaint and pretty as a dessert fruit, and might repay the trouble of crossing with the Golden Drop. Even the poor despised Sloe would furnish an importantly instructive experiment in showing to what an extent the austerity of its wild produce would be modified by the influence of a rich and saccharine garden Plum.

I do not think much deliberate crossing has been done with the Cherries. A few subjects of well-defined races might be crossed together. The Morello produced sterile seedlings when experimented upon by Thomas Andrew Knight, yet I cannot help thinking that further trials might meet with success, or at any rate verify a result. I need hardly say that to a really scientific mind the verification of an experiment, or the setting at rest of an old doubt, is a gratification of the highest order.

After the fruit tree question, of which I fear you must be almost tired, we pass naturally to the shrubs. Are our small fruits incapable of further improvement? Not while Red Currants are sour, and—I now address myself to an especial audience,—Men of Lancashire, I call upon you to produce an eatable prize Gooseberry. Red Currants still obstinately persist in being acid, although they were once worked at by a master hand; but a few generations under the care of the hybridist would undoubtedly improve the Gooseberry in flavour as well as in size. Your huge Lancashire Roaring Lions might be made rich with the honied juices of the old Rough Green, Red, and Yellow berries, and the "unsapid" pachydermatous, prize-taking monster might become a mouthful for a prince.

I had prepared materials for carrying out far more fully my intention in treating of this subject. Time flies, and I have only got to Gooseberries.

So now I will bring my fragment, for it can perforce be no better, to an abrupt conclusion. I hope I have inculcated an important principle, to wit, the getting out of a rut; and I wish all good fortune and success to the bold traveller in untrodden ways.—R. T. Clarke.

P.S.—There is no earthly reason why we should not cross the Pine Apple.

ON THE IMPROVEMENT OF PLANTS

BY SELECTION, HYBRIDISING, AND CROSS-BREEDING, HAVING SPECIAL REFERENCE TO THE HOLLYHOCK AND THE ROSE.

There are two important methods of procedure open to him who may wish to engage in the modification, or improvement of plants. 1, Selection. 2, Hybridising and cross-breeding. The first method, "selection," is exceedingly simple, and may be successfully followed by anyone who possesses or who may acquire the habit of observing correctly. The second method, "hybridising and cross-breeding," is more complex, and requires, in addition to the habit of observing correctly, an acquaintance with at least some of the laws of vegetable physiology. In adopting the former, we seize upon certain variations or phenomena which we meet with in Nature, and endeavour to "fix" or render permanent that which we are accustomed to call accidental; in pursuing the latter, we start with a conception which we labour to convert into a fact. To the mere man of business, selection is usually the more attractive; the method is more suitable to his habits of thought and practice; but to the scientific mind hybridising or cross-breeding are usually more inviting, and the results more satisfactory. To both methods are we largely indebted for improvements in the vegetable kingdom, and it would be exceedingly difficult, perhaps impossible, to say how much we owe to the simple process of selection, and how much to the more complex and scientific labours of the hybridist.

It will be my purpose to place before you, as fully and clearly as I can, a few instances of improvements by both processes, drawing, as far as practicable, from my own observations and experiments.

First of selection. It is well known to observers in this field that most plants, and especially cultivated plants, when raised from seed, are prone to vary:—

> "The earth was made so various, that the mind
> Of desultory man, studious of change,
> And pleased with novelty, might be indulged."

We sow a handful of seed, and in some cases scarce any two of the young plants which arise therefrom prove absolutely identical; there is a difference in size or appearance, in form, colour, or texture. This shows an inherent capacity of progress or development. It is more marked in cultivated than in wild plants, and the tendency increases under cultivation; yet it appears in both states. Among wild plants I have met with no more striking example than that of the Lychnis diurna, which grows plentifully in the hedgerows surrounding my nurseries at Waltham Cross. The flowers of some of these self-sown plants are much larger than others, some are of a deeper colour, and some of a smoother aspect and more rounded form. The habit of growth of the different seedlings also varies greatly. The Dog Rose (Rosa canina) is another case in point. Examples of this fact are, however, plentiful enough in Nature, and might be adduced almost without limit if required. But it is only by selection and cultivation that the most attractive forms of these natural variations can be fixed and turned to practical account. The advanced Lychnis, if neglected and allowed to seed in its native wilds, would probably produce offspring for the most part similar or inferior to itself, except rarely and at long intervals of time. If, however, removed to a superior soil, more highly nurtured, and the seeds gathered from the most attractive plants only, the improvement would probably go on gradually but regularly from generation to generation.

To elucidate further the principle and results of selection, let us suppose an intelligent agriculturist observing in his Wheat fields some individual plant of Wheat more vigorous in growth, or more prolific, longer, stouter, and fuller in the ear than those by which it is surrounded. He wishes to retain this variation, knowing that if he can succeed in so doing he will thereby increase his crop. He sets a mark upon this plant, saves and sows the seeds separately, selects again and again, from year to year, those most in advance, be they few or many, until the variation first noticed has become constant and fixed, and, perhaps, even further developed. This process of selection usually requires to be pursued through several generations, some of the individuals from each successive sowing continuing to advance on the line first indicated, and the whole drawing closer together, till in the end he establishes the purity or constancy of the race. Once established or fixed, the variation will remain an improved race or breed, and if the individual plants composing it are not absolutely identical, they are yet sufficiently so for practical purposes. In this instance we have supposed a case of selection for a prolific tendency, but the same principle may be applied to any other desired improvement, as quality of grain, earliness or lateness of ripening, quantity or quality of straw, and so on. Or, to take other instances from agriculture, the farmer observes among his Mangold Wurtzel a plant remarkable for the large size of the root and the small size of the top—among his Turnips a root that has stood the frost uninjured, while others surrounding it have been materially damaged; he selects the Mangold with the view of increasing the weight of his crop without drawing too much from his land, the Turnip for the sake of obtaining a hardier race of this valuable root, and follows up the process of cultivation already described, until he fixes the recognised and coveted features.

As with the agriculturist so with the market gardener, whose superior vegetables are in great part due to the judicious selection of the individual plants from which he saves his seed. Perhaps half a dozen of the whitest and closest heads of white Broccoli are selected off many acres as the source of the crop for the ensuing year; and other vegetables and flowers—as Onions, Cabbages, Lettuces, Stocks, &c.—are subjected to the same careful process of selection.

To continue: Our seed-growers work on the same principle, although in place of leaving a few only of the best, the quantity of seed they require compels them to rest satisfied with eradicating a few of the worst only, and the value of their crop of seeds is, or should be, in proportion to the thoroughness of the selection, or, as the growers term it, the purity of the stock. If in the Bill on the adulteration of seeds now before Parliament, a clause could have been inserted insuring the purity of the stock, I should have considered that by far the most important part of the measure.

I have intentionally given prominence to the above cases, because I believe the farmer, market gardener, and seed-grower, whatever attention they may be giving to cross-breeding now, have in the past derived their improvements chiefly, if not entirely, from selection; whereas, the horticulturist has been for many years past working more or less ardently in both fields. There has, however, I believe, even with him, till recently, been but little hybridising or cross-breeding with vegetables; more, perhaps, and for a longer period, with fruits; and most of all, and for the longest period, with flowers.

The vegetables and flowers which I have improved by selection merely are somewhat numerous; among the former, Parsley and Brussels Sprouts.

Parsley was the first plant I endeavoured to improve by selecting for seed one or two individual plants from a large bed, the unusually double or curled leaves of the selected plants having pleased my fancy. The result was so striking in the following year that I was encouraged to persevere, and did so from year to year with increasing success, until Paul's Parsley became household words. Brussels Sprouts, the seed of which it was considered necessary in those days to import from the Continent, was the next plant taken in hand, and I proved over a series of years, to my own satisfaction at least, that it was neither the continental soil nor air, but the practice of a vigorous selection, that gave to the continental seed an acknowledged superiority.

The Aster was the next plant taken in hand, and with the same results. Stocks, Pansies, Roses, Cinerarias, Hollyhocks, Zonal Pelargoniums, Chinese Primulas, and Polyanthuses, were taken up in due succession, similarly dealt with, and similarly improved.

The Hollyhock would seem to demand at my hands more than a passing word. To the improvement of the flowers of this plant by selection, I gave long and close attention, from the year 1853 to 1857. Let me submit to your notice some of the results of the sowing of seeds from selected plants, without the interposition of artificial fertilisation. The variety Gloria Mundi (yellow) gave Sulphurea perfecta, Argo, El Dorado, Queen of the Yellows, and King of the Yellows, all yellow flowers; and Charles Barron, buff. El Dorado, a smooth yellow flower, gave yellow flowers only, bright in colour, but rough and irregular in form. Lady Willoughby d'Eresby (cream colour) gave a lot of rough dirty whites. Lady Franklin (deep pink) reproduced itself, and also gave sundry good rose-coloured flowers. Lady Palmerston (blush) gave a very fine brood of peach-coloured and pink flowers. Purple Defiance (purple) gave a rough lot of purples. Attraction (pink) gave a fine brood of pinks. Princess Royal (cream and chocolate) gave a rough lot of dirty cream and chocolate-coloured flowers. Crusader (pink) reproduced itself, and also others of similar colour, varying in form. Celestial (blush) reproduced itself, and various shades of blush of superb quality. Memnon (a fine crimson flower) produced regularly some plants bearing crimson, and others bearing purple flowers. Omar Pacha (cream edged with white) reproduced itself. A purple seedling of good form and substance gave some purple and some blush-mottled flowers of very indifferent quality. A salmon-coloured seedling of fine quality gave flowers of the same colour, but of indifferent form. A fine dark shining crimson seedling gave flowers, orange, fawn, and buff, of middling quality, but no crimson. A white-edged seedling gave flowers like the parent, but as a rule not so good. A fine rosy peach-coloured seedling gave rubbish. A nankeen-coloured

seedling reproduced itself almost without variation. A pure primrose seedling of very high quality gave some primrose-coloured flowers and some primrose with dark base, usually inferior to the parent. A French white veined seedling gave a lot of prettily and variously veined flowers. An orange-buff seedling gave also some few prettily veined flowers among many very rough ones, of the colour of the parent. A fine purple seedling gave purple, marbled, maroon, and lilac flowers, all of superior quality.

Now, it might appear at first sight that the above results militate against the theory of improvement by selection merely. But it is not really so. It must be told that the above is a record of general results only. In most cases few or many individuals might have been selected in advance of the parent. Let it further be remembered that this is the result of one year's growing only, and it certainly proves that a variation cannot always be fixed by a single effort, which we are perfectly free to admit. It shows also the tendency of the mass of seedling plants raised from cultivated or advanced varieties to revert to a less civilised state. It shows further, that a variation once obtained, new ground once broken, often proves a fertile source of further variation and advancement. But of this I shall give an example by-and-by. Now, I do not think that the variation in colour recorded in some of the above cases was due to fertilisation either by insects or other instrumentality. But it might be so. I merely express an opinion on this point, founded on the fact that the progeny of some varieties varied but slightly throughout successive annual sowings, whereas that of others varied greatly. The inference I should draw would be, that some variations are capable of a more rapid development, some are more sportive, and some more readily fixed than others.

It will be further inferred from the above facts that the finest flowers do not always produce the finest progeny. And I have found this circumstance corroborated in dealing with other plants. Certain individual sorts furnish a fine brood; others, apparently equally good sorts, an indifferent brood. Sometimes a flower or fruit of indifferent quality will produce a high-class progeny, and a high-class flower or fruit an inferior progeny. The whole question is, I admit, beset with difficulties, and offers a fine field for observations and experiments. The exceptions to the rule, that the best flowers proceed from the best parents, are numerous. Notwithstanding, unless we possess "special knowledge," we cannot do better than work upon this rule; for, if we reject it, we have nothing so good to put in its place.

One word as to the special knowledge just alluded to. Now and then a variation, peculiarly fitted for the work of progress, will arise. Many years ago, a Pansy, named Queen Victoria, raised by the late Mr. Thompson, of Iver, proved of this character; and more recently the Roses Général Jacqueminot, Jules Margottin, and Victor Verdier, may be taken as prominent instances. From these in their day, and for a certain period, many more good flowers were raised than from all others of the period put together. Now, if one acquires this special knowledge, there is sure ground to work on. But I know of no law by which this quality of a plant can be determined in advance. In the present state of our knowledge, I conceive that it can only be ascertained by observation and experiment.

I have raised many thousands of seedling Hollyhocks, Roses, Zonal Pelargoniums and other plants, simply on the principle of gathering the seed from the most advanced plants and flowers without any attempt at cross-breeding. My success under this method of proceeding has been greatest with Hollyhocks, as I could claim at one time (about 1857), the finest Hollyhock of almost every colour as of my production. This I account for by the fact that the subject was a good one for experiment. Although a flower long known to us, it had not been long subjected to high cultivation, and was fully ripe for improvement. With the Rose the case was somewhat different. It had been experimented on by clever and industrious men in France for a number of years, and, doubtless, I was here traversing ground which some of them had exhausted long before. However, success here has not been altogether denied me, and to which I shall have occasion to allude by-and-by. Of Zonal Pelargoniums, I was fortunate enough to become the possessor of a remnant of stock left by the late Mr. Donald Beaton; and while many of the variations and improvements that have issued from my nurseries are the result of mere selection, others have been carefully and systematically bred. The Polyanthus is a flower with which I am now carrying on experiments, with the view of rendering it more available in spring gardening. Four years ago I selected certain colours from a bed of mixed seedlings, with the view of saving the seeds of each separately, hoping in time to be able to reproduce each colour true from seed. The first sowing produced all colours from each variety, and while subsequent sowings have done the same, yet each successive sowing brings a larger proportion of the colour of the parent; and I do not doubt that ultimately each variety will become fixed—that is, will reproduce itself true in colour from the seed.

With regard to the progress of improvement after selection, it would appear that the greatest progress does not take place when the variation is young. The most marked progress from a cultivator's point of view seems to occur when the variation has been some little time under cultivation, but before it loses the extra vigour not uncommon to selected variations. A case illustrative of this view has recently come under my observation. It is that of a plant of the Primula sinensis, which I recently exhibited before the Royal Horticultural Society, under the name of Waltham White. It is a white-flowered variety with red leaf-stalks (the white-flowered variety has commonly greenish white leaf-stalks). The growth is exceedingly vigorous, the plant bearing a huge pyramidal truss of large pure white flowers, of great substance. It is, in fact, a giant among Primulas, and a giant of goodly and fair proportions. Now, nothing could have been more unpromising than the original variation from which this grand result has been obtained. It was a coarse weedy-looking plant, bearing rough misshapen flowers; but there were the distinct features of extraordinary vigour, and the red leafstalk. The first year's sowing from this plant produced more variation than improvement; the second more improvement than variation; and now, in the fourth year, the characters above described seem fixed, for all the seedlings raised from a choice pod of seed have bloomed so nearly alike in colour, size, form, and habit, that the variation may be fairly pronounced improved and fixed.

Thus far I have confined my remarks to the variations of plants from seed which appear to arise spontaneously, and are of everyday occurrence. But there are other variations occasionally taking place, which are known to cultivators under the name of "sports." Sports are variations from the leaf-bud rather than from seed, and I class them under selection, because in their case man does not intentionally step in with the view of giving a turn to the workings of Nature. Cultivation may, and in many cases probably does, induce "sports," but cultivation is not deliberately pursued with that object. As an example of these we may instance the well-known case of the Nectarine, which was a sport from the Peach—that is, a branch of a Peach tree produced the smooth-skinned and otherwise different fruit known as the Nectarine. My first efforts at improving the Rose were made in 1843, and were induced by discovering a sport. I observed a branch and flower of the Bourbon Rose Proserpine, then recently introduced, of extraordinary vigour; the flowers were larger and somewhat lighter in colour than in the original; the leaves were of a lighter green, more obtuse, and destitute of the customary red nerves and red colouring round their circumference. This, which I believe I am right in speaking of as a sport, was, nevertheless, not a very marked example of this tendency. It was cultivated separately and fixed, but did not depart sufficiently from the original to be thought worthy of a new name, and was, consequently, sold as a superior variety of the Rose Proserpine. About the same time I observed a branch of the Rose du Roi, bearing pale flesh-coloured flowers. This branch was propagated, and the new colour fixed. When about to distribute this as a novelty, to my surprise I received it from France, under the name of Celina Dubos! Now, although I know nothing of the history of Celina Dubos as received from France, I yet know that it was identical with my sport, and I think it is reasonable to conclude that it originated in the same way. Also, about the same time, I observed a branch on the Rose Dr. Marx, producing leaves finely striped with gold; and a branch of the Bourbon Queen, with leaves beautifully variegated with white. Both of these sports were propagated and fixed. Of Roses, the Moss group is the most inclined to sport. I have, in days gone by, frequently seen two or three varieties of the Moss Rose growing on the same plant. I have seen the Baronne Prevost, which is naturally a double rose-coloured flower, produce striped flowers, and others nearly single. I have also seen Mrs. Bosanquet, a white Rose, produce a branch bearing red flowers.

But the most notable recent case of this tendency is that of the new Double Crimson Thorn; and this is remarkable in having been observed in two different places about the same time. It should be told, however, that both these plants had been purchased from the same stock. The particulars of one case are as follows:—A tree of the Double Pink Thorn had been planted in a garden some fifteen or sixteen years, when a branch was observed to have started away from the centre of the tree with unusual vigour. It flowered, and lo! the flowers were crimson instead of pink, presenting a marked contrast to those on the lower part of the tree. The leaves, too, were of larger size, greater substance, and more deeply lobed. Young plants were propagated from this branch by budding and grafting, and the character was fixed.

A few words with regard to the fixing of variations or sports seem desirable here, and with that I shall close this part of my subject. We have seen that variations or sports are, when reproduced from seed, liable to vary greatly in character, with a general tendency to revert to the type. From the first sowing there will probably be but few like the variation, but by successive repetitions of the process of sowing and selecting the variation is at length fixed. It is thus that many of our races of annuals, as Asters, Stocks, Clarkias, Candytufts, Tropæolums, and the like, not readily propagated otherwise than from seed, have been obtained. But the process of fixing variations or sports from the leaf-bud is almost certain to proceed without interruption. You graft, bud, or make cuttings of the sported branch or plant, and the plants so propagated remain unchanged.

I will now proceed to the second part of my subject—namely, the improvement of plants by hybridising and cross-breeding. I have said that in hybridising and cross-breeding we start with a conception which we labour to convert into a fact. For example, we find existing in two separate flowers or fruits certain high qualities, as size, colour, form, flavour, mien, &c., which we seek to combine in one and the same individual. We cross or hybridise these two plants, sow the seeds, and after few or many attempts, one out of many is likely to give the desired result. As a guide in hybridising and crossing, it

should have been noted that our best observers are of opinion that hybrids and cross-breeds derive their form and habit in greater part from the female, the colours of the flower from the male, while the constitution may be acquired from either parent.

By hybridising we understand the crossing of two different genera or species, by cross-breeding the intermixture of two different varieties of the same species. Practically speaking, the work is the same. It would be out of place here to enter into a lengthened description as to how far the different species of plants may be hybridised. Doubtless, there are limits: I have tried on various occasions, and in various ways, to obtain a hybrid between the Pyrus spectabilis and the Cydonia japonica, two different genera, but without success; and I announce this because to acknowledge a failure is sometimes as useful to others as to record a success. On the other hand I have succeeded in raising hybrids between the Moss Rose (Rosa centifolia), and the Alba Rose (Rosa alba), two different species; also between a hybrid China Rose (R. gallica crossed with R. indica), and Rosa multiflora. Then, again, I have often tried in vain to obtain crosses between certain varieties. So that it does not seem to be exactly a question between species and species, or between variety and variety, as these are at present classified by botanists. I have found, however, as a rule, that the more nearly allied the varieties the more certain is the cross. The Tea-scented and Noisette Roses are found to cross readily, but then, although these form separate floricultural groups, they belong to the same species, R. indica. But the Hybrid Bourbon and Moss Roses also cross readily, and here we have intermixed three different species according to most botanists—R. indica, R. gallica, and R. centifolia. The grandest and the most beautiful of all the floral groups of the Rose—the Hybrid Perpetual—has a curious genealogy: R. gallica crossed with R. indica produced the Hybrid China; the latter crossed with an autumn-flowering variety of the R. damascena produced the Hybrid Perpetual.

My first attempt at crossing the Rose was made in 1843. I crossed three flowers of the Tea-scented Rose known as Gonbault with the Bourbon Rose Souchet, with the view of obtaining a dark-coloured Tea-scented Rose. Let me call these flowers C, D, and E. C produced a very large pod, which ripened perfectly, and gave ten large seeds. D produced a medium-sized pod with nine seeds of very unequal size, one being very large, four large, and four small. E produced a small pod, which contained thirteen small seeds. Of these thirty-two seeds four only germinated! Three of the plants were curious cross-breeds, of no floral value, and having little in common with either parent; and one, in leaf, habit, and flower, was very similar to the wild Dog Rose! As the seeds were sown in pots, and placed under glass, I do not think any stray seed could have found place among them. I was here, no doubt, unfortunate in the choice of my parent or parents, and I regard this issue as an instance of the well-known tendency which the offspring of some cultivated plants have of reverting to the normal form. The same year I crossed about forty other flowers, but the crop of seed was indifferent, and the result nothing worthy of record. This non-success led me to submit to microscopical examination the flowers of a number of varieties of the Rose, with the view of ascertaining which were likely to prove the best seed-bearers. The result of that examination is given in the "Rose Garden," second edition, pp. 96, 97. The conclusions I drew were:—1st, That certain varieties are sterile, incapable of forming perfect seeds under any circumstances. Of these I found such kinds predominate as roll the petals inwards, the centre of the flower being quartered in the manner of a crown. In others the pistils were weak or imperfect. 2nd, That many kinds where the pistils are perfect, which in their natural state form seed-pods that wither before arriving at maturity, may be induced to perfect their seeds by artificial fertilisation. This class of Roses is the best for him who intends raising seedlings to choose his female parents from, because there is little here to interfere with, mar, or counteract his plans. Be it remarked, however, that there are certain kinds which must not be confounded with the above—kinds which, owing to the length of time the seed-vessels are in arriving at maturity, never perfect their seeds in this country. 3rd, That those kinds which we find seeding abundantly in their natural state are self-fertilised, and that their abundant production of seed is due to this point mainly—the more perfect development of the organs of reproduction, especially the polleniferous parts of fructification.

Thus fortified I selected some twenty sorts of Roses, planted them in a separate corner of the nursery, and in the month of June, 1846, crossed nearly a thousand flowers. Success in seeding was complete. On the 30th of September of that year I gathered 223 well-ripened pods of seeds, some of them of extraordinary size. Two successive gatherings, of about one hundred pods each, were made at intervals of about a month, the whole number of hybridised and crossed pods gathered and stored amounting to 444. The seed was sown the same winter, vegetated during the succeeding spring and summer, and the seedlings bloomed at intervals over the next six years—that is to say, some bloomed the first year, others were six years old before blooming. The result of the hybridising and cross-breeding was apparent in many cases, but not in all. Two of the most striking and complete I will describe.

I had long thought that a dark bright-coloured climbing Rose was a desideratum, as at that time nearly all our climbing Roses were white or yellow. To obtain this I hybridised the Rose Athalie (hybrid Bourbon) with Russelliana (multiflora). Paul's Vivid, a bright crimson climbing Rose, of great repute in its day, and even now sought after, was raised from this effort. Again, I had conceived that if anything could add to the beauty of the Moss Rose, it would be to impart to it the exquisite tint of the R. alba or Maiden's Blush. To obtain this I hybridised the Moss Du Luxembourg with an Alba Rose, and among the offspring was a Moss Rose, with flowers like the Maiden's Blush, afterwards named Princess Alice.

A few years later I raised from one and the same sowing of English Rose seed, the Roses Beauty of Waltham, Lord Clyde, Red Rover, Globosa, Princess of Wales, Dr. Lindley, and, I believe, Duke of Edinburgh. Unfortunately, in these cases the parentage of the offspring was not preserved.

The next flower with which I experimented was the Hollyhock. I crossed numbers of these flowers in the years 1853-7. A blush seedling crossed with White Globe, with the view of obtaining better blush flowers, gave, among others, ten seedlings answering to this end. Fireball Superb, crossed with Metropolitan, with the view of obtaining a better scarlet Hollyhock, gave one plant of the character sought. A pink seedling crossed with Lizzie, with the view of combining the bright colour of the former with the quality of spike and flower of the latter, gave a large number of seedlings, twenty-three of which were realisations, more or less complete, of the object sought. These are three cases selected from many of similar import. With regard to the results in crossing the Hollyhock, I may add that Mr. Reeke, of Clewer, at one time a most successful raiser of seedlings, raised three of his most marked improvements, all differing in colour, from one fertilised pod of seed, whereas with seedlings raised from seed-pods not fertilised, he found the degree of progress slow and uncertain.

Some of my latest efforts in hybridising and cross-breeding have been directed to Zonal Pelargoniums. Attempts to hybridise the Zonal varieties with the Unique have never succeeded; and yet Mr. Wills has obtained hybrids between the Zonal and Ivy-leaved species, probably as distantly removed. He tells me that he hybridised some thousands of flowers without success, until he thought of dipping the hybridised flowers into water after applying the pollen, by which means he obtained seeds and seedlings, two of which, evidently hybrids, are now before the public under the names of Willsii and Willsii rosea. My experiments in cross-breeding have been numerous, but having been pursued chiefly with my own seedlings, which are unknown, I have little that is tangible to place before you. Two or three cases, however, in which the varieties were afterwards named and sold, may prove interesting, and give a clue to those who may care to trace them. Mrs. Pollock, crossed with a green-leaved seedling Zonal, produced some green-leaved, some golden-variegated Tricolors, and one golden-edged variety after the character of Golden Fleece. Amy Hogg, crossed with Crusader, gave the result sought after in Evening Star. Governor, crossed with Alexandra, also gave the result sought after in Clio. Dr. Hogg, crossed with Rebecca, again gave the result sought after in Pæan. Model, crossed with Firefly, gave also a form intermediate between the parents, which was afterwards named Annibal.

Leaving flowers, let us glance momentarily at fruits. I have now growing in my nurseries a breed of seedling Strawberries, the result of various crosses, the parentage on both sides having been carefully preserved. As they are not yet named, I can only speak of them as seedlings. Two seedlings, raised from Sir Charles Napier crossed with Myatt's Pine, are worthless. Of eight seedlings, between Eleanor and Carolina superba, four are worthless, one is flat and rough in flavour, one resembles Keens' Seedling in appearance, but is of a much richer flavour: one bears large fruit, remarkable for its solidity, of the shape of British Queen, with the fine rich flavour of Myatt's Pine; and one is a full-sized handsome fruit, of fine colour and good flavour, bearing abundantly, and of hardy constitution. Two seedlings between Oscar and Myatt's Pine are deficient in flavour. Of eight seedlings between Sir C. Napier and Crimson Queen, three are large handsome fruit, solid, heavy, of good colour and rich flavour; one is flat and insipid, one is very acid, and three have no prominent character. Of five seedlings between Filbert Pine and Myatt's Pine, one is large, of fine flavour, and very juicy; one is small, of good colour and flavour, solid—the flesh notwithstanding very tender; and three, one of which is a prodigious bearer, are deficient in flavour. Four seedlings between Oscar and British Queen are all deficient in flavour. Of seven seedlings from British Queen crossed with La Constante, five are worthless from the fruitist's point of view, although one is so distinct in habit as to be scarcely like a Strawberry, and one so positively nauseous in flavour that it leaves an unpleasant sensation on the palate long after tasting, yet from the same fruit and parentage one is of good flavour and another of positively fine flavour. Of eight seedlings raised from Admiral Dundas crossed with Crimson Queen, four are small and almost flavourless; two are large handsome fruit, of fine colour and fine flavour; one is very late, of pleasant but not rich flavour; and one is early, the fruit large, of moderate flavour, and produced in extraordinary quantities.

I shall now conclude these remarks with a few practical deductions. We have seen that in the improvement of races much may be accomplished by mere selection, but hybridising and cross-breeding, if in some cases and with some experimentalists unsuccessful are in the hands of others a shorter and surer road to the attainment of a given object. We have seen that our best vegetable physiologists are of opinion that hybrids and crossbreds derive their form and habit from the female, the colour of the flowers from the male, while the constitution may be acquired from either parent. This may be generally true, and is sometimes true, but the exceptions are so numerous that they

cannot, according to my experience, be said to prove the rule. It is generally admitted that the most perfectly developed flowers and fruits are the best for the improver to work upon, and this is, I believe, true as a rule, although still attended with exceptions. Personally I have learnt from my labours in this field never to lose heart or hope. For sixteen years, from 1843 to 1859, I had laboured with such qualified success in raising seedling Roses, that I had then minimised the amount of labour by omitting the costly process, in point of time, of keeping notes of parentage, &c., when in the following year, 1860, I was more than compensated for all past labour by the extraordinary flush of success already stated. I say, then, to my brother horticulturists who may be working in this field—Never despair; persevere and wait.

"Let us then be up and doing,
With a heart for any fate;
Still achieving, still pursuing,
Learn to labour and to wait."

My experience in selecting, hybridising, and cross-breeding tells me that he who is seeking to improve any class of plants should watch narrowly, and seize with alacrity, any deviation from the fixed character, and the wider the deviation the greater are the chances of an important issue. However unpromising in appearance at the outset, he knows not what issues may lie concealed in a variation, sport, hybrid, or crossbred, or what the ground newly broken is capable of yielding under careful and assiduous cultivation. If we would succeed in this field we must observe, and think, and work. Observation and experiment are the only true sources of knowledge in nature, and while observing and experimenting we should above all things guard against prejudices.

My remarks have hitherto been chiefly of horticulture, and addressed to horticulturists. But there are three other great and important classes of the community who are deeply interested here—the agriculturist, the manufacturer, and the merchant, to each of whom I would momentarily address myself.

To the agriculturist I would say, You have of late years practised draining, deep cultivation, and high manuring, and the increased fertility of your soil has largely rewarded your industry, enterprise, and skill. The next step with you is the improvement of the races of your cereals and root crops. I have in the opening of this paper shewn what you may accomplish by selection merely, but you may do far more by cross-breeding. I believe that your produce may be improved and increased by this means beyond what the boldest thinker would at this moment dare to declare.

The manufacturer is also deeply interested in this question, in at least so far as the raw material he uses is drawn from the vegetable kingdom. As the horticulturist has by selection and cross-breeding increased the size and substance of his flowers, so may the manufacturer or his growers, by selecting from other special points of view, increase the productiveness, strengthen or soften the fibre of their cotton, flax, hemp, and jute.

Again, if the horticulturist can increase the size and productiveness, advance or retard the seasons, and improve and vary the flavour of his fruits, why should not the merchant or his agent do the same with his teas, coffees, cocoa, and other vegetable productions? There can be no question here that the one is as open to modification as the other; it only requires the thoughtful interposition of the skilled brain and hand.

Thus, we see how vast are the interests involved, how rich in prospect the unexplored territory in which the horticulturist may be said to be the pioneer. The agriculturist, the manufacturer, and the merchant should in their own interests, as well as in the interests of society at large, lend him a willing and a helping hand, and he in his turn should rejoice to find his labours acceptable and capable of so wide and beneficial a diffusion. I stand before you this day and declare, what I honestly believe, that we are here waiting, but working, at one of the chief gateways of a grand Temple of Science; and not many years will elapse ere its secrets shall be revealed, to the surprise, delight, and profit of the human race.—William Paul, *Waltham Cross.*

[We shall publish other papers next week.—Eds.]

STRAWBERRY RUNNERS.

It is an error to suppose that the first runner is less prolific than the second on the string. I invariably choose the first runner, and cut off the string beyond it. The Editors have given the true reason. Some soils are so good that they drive the runner into foliage instead of crowns. This does not often occur. There is another error in the opposite direction—viz., that only the first runner is prolific. If the plant is not staminate (*i.e.*, a male plant; most of our European sorts are hermaphrodites), the last runner would be equally prolific, but it could be planted later, and hence would not bear so well as the early runner.—W. F. Radclyffe.

Covering Seeds.—I may have missed seeing it recommended, but I have never found any covering for small seeds equal to short grass mown from the lawn. This is strewn over the seeds to about half an inch in depth, and then the usual watering given. It soon shrivels and becomes light, so that the seeds come through it freely. The birds, at least here, never attack them, and my crops never fail. At this Cabbage-sowing time it will be found most efficient.—T. R.

AMONG THE SWISS LAKES.—No. 2.

Geology and archæology have taught us from facts—and facts, like figures, are tough evidence, that we have wrongly interpreted the only written record of man's first existence on our globe. Those facts tell that man was here ages before that in which he has been usually thought to have been created. Prominent among those facts are the remains of the *Pfahlbauten*, or lake-dwellings, in Lake Zurich. That word of ugly aspect is a pure German word, signifying "pile-buildings"—houses on a structure of piles or posts. The inhabitants lived many thousands of years ago, but have left "no record of their date remaining" but the submerged remains of those piles, the stone implements they employed, and fragments of their daily surroundings that have been extraordinarily preserved in the peat formed where water had been below their dwellings. The first discovery of the remains of these dwellings has thus been told:—"In 1853, the inhabitants of Ober-Meilen, a village on the lake of Zurich, availed themselves of the unusual lowness of the waters to reclaim a piece of land from the lake. The excavations disclosed a number of remains of deeply-driven piles, formed of various forest trees. In the mud around these piles the attentive investigation of Dr. Keller detected the remains which threw the first light on the nature of the discovery. There, heaped together, lay stone axes, and hammers, and chisels or celts with their hafts of horn, rude implements for crushing corn, a great variety of coarse pottery, implements of bone, lance and arrow-heads, knives, saws, &c., all of flint, in rich abundance, although flint is not a natural product of Switzerland. Some of the smaller celts, or chisels, are formed of nephrite, a species of transparent jade, a stone imagined to be entirely peculiar to the East. The saws, in particular, are curious examples of human ingenuity under difficulties. They are formed of length in flakes of flint, one edge of which is finely notched, and the other fitted into a neatly formed long wooden handle, the perfect preservation of which may probably be attributed to the antiseptic influence of the peat wherein it had so long remained. A kind of bituminous cement appears to have been used for securing the saw in its handle. The

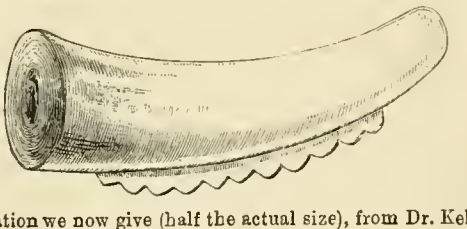

illustration we now give (half the actual size), from Dr. Keller's drawings, is from the lake of Neuchâtel, and presents the singularity of a handle formed from the tip of a stag's antler. These saws were probably used for working horn and bone.

"One would like to know how the pile-driving was managed, but driven the piles were, at a distance of from 1 to 300 feet from the shore, at a depth of 6 or 7 feet, gradually advancing into deeper water. They were then extended parallel with the shore till the *pfahlbau* assumed somewhat of the form of a narrow parallelogram. At Morges, on the lake of Geneva, the piles extend '1200 feet in length, by 120 in width, giving a platform surface of some 18,000 feet. On this M. Troyon calculates that some 316 cabins may easily have stood; which, only allowing four persons to a cabin, would give a population of 1264.' On these piles, driven at short intervals, was laid a platform on which stood the cabins, constructed, as there is good authority for believing, of wattled work plastered with clay. From the extraordinary number of reliques found it is supposed the planks of the platforms were not set close together, and that things were hence continually falling through; but there would scarcely appear need for such an hypothesis. It is clear that the great mass of *pfahlbauten* were fired, purposely or accidentally. In buildings so constructed fire would spread too rapidly to allow the inhabitants to save much of their property, which accordingly would sink to the bottom of the lake. Indeed, the carbonised state of many things, especially the vegetable products, has preserved them for the examination of modern science.

"In the masses of carbonised grain discovered at Wangen,

and elsewhere, Professor Oswald Herr recognises several cereals,—Triticum vulgare; Triticum dicoccon; also Hordeum distichon, and Hordeum hexastichon. The *pfahlbauten* of Wangen and Robenhausen have also furnished abundant examples of a coarse bread savouring rather of bruised corn than meal. It was probably baked on hot stones, and covered with hot embers, just as in the Rigsmaal Saga 'Edda drew out from the embers a bread cake, heavy, sticky, and full of bran.' In the same *pfahlbau*, too, were stores of Apples and Pears cut into halves and quarters, and dried in the sun for winter food. The custom holds in Switzerland to this day, and these dried Apple cuttings are sold by measure in the markets under the name of *schitze*. From the size of some of this carbonised fruit it would appear that the Apples must have been of a cultivated kind,—so these people were acquainted to a certain degree not only with corn, but with fruit culture.

"Flax and hemp they certainly had, and the means of spinning it, which was of the last necessity for their nets. Nothing exists to show any knowledge of the art of weaving, but they contrived to manufacture a coarse flaxen plaited material. In addition to their other means of subsistence they had always the lake at command, and the great variety of fish-hooks discovered shows that they knew how to take full advantage of it with the line as well as the net."

Great, indeed, was the interest with which I inspected the numerous relics of the Pfahlbauten preserved in the Zurich museum. The sharpened ends of the piles, I think, show that they were of a Coniferous tree, probably Abies excelsa. The Apples, halved, are black masses; they were evidently carbonised by exposure to intense heat whilst the air was excluded. They were probably stored in close vessels. The pulp is black, a mere mass of charcoal; the core is somewhat paler, and the pips are quite distinct, as shown in this portrait of one.

What thoughts crowd upon one! What reflections that we are looking upon forms that other human eyes looked upon, since which so very many thousands of years have passed! Then, probably, as now, a winter store of dried fruits was essential for the preservation of health. I pondered over the uninterrupted succession of Pear, Cherry, Walnut, and Apple trees that margin *all* the roads in the Swiss valleys, and wondered what could be done with their produce. I at last was told. In winter the dried fruit is almost the only vegetable produce, except bread, that is available to mingle with their animal food. In some alpine districts that animal food is only such as has been salted, and the consequences have been told by the Rev. Mr. Macmillan in his most interesting little volume, "Holidays on High Lands." Speaking of the monks of St. Bernard, he says, "During winter they have no fresh meat, being obliged to subsist upon salted beef and mutton, usually killed and preserved in September, and, which is worse still, they have no vegetables, all attempts at gardening in the place having proved abortive, so that not unfrequently scurvy is added to their sufferings."

The fruit of the Cherry, including the stone, is crushed, fermented, and a spirit distilled from the mass, so potent and pleasant, that it is degraded by being named, as it is named—"Cherry-*water*"—Kirschwasser.

In the Zurich museum are preserved many other relics besides those of the lake-dwellers; but I must not linger here over "The Twelfth-day Queen," Jane Gray's neatly-written letters to Bullinger, nor to the "infirm-of-purpose" looking scrawl of Cranmer; but I note more fittingly for your pages, that there are original and very satisfactory portraits of Conrad Gesner, Scheuchzer, and Lavater.

Now, for a few words on the vegetable products of the Swiss valleys, and first of these must be the fruit trees, for no object strikes a stranger more forcibly than the continuous orchards and vineyards which line both sides of all the roads in all these valleys.

The vineyards almost exclusively are confined to the mountain sides, where they blend with the valleys, and they do not, by their produce, deserve much further notice. With scarcely an exception, the wines manufactured from their Grapes are thin and acid, and not one is equal to good cider. The only exception was that to which was applied the not-over-refined name of Lunfrauenmilke—"Pretty Maid's Milk." I was laughingly told that we English expect every country like our own to have districts noted for something pleasant to the palate, such as our Yorkshire hams, Norfolk dumplings, and Cheshire cheeses, and to celebrate anniversaries by special eatables, as plum puddings at Christmas, buns on Good Friday, and pancakes on Shrove Tuesday. But I had an avalanche of instances to retort upon my assailant, for every Swiss town has some gourmandic specialty. Bale, the first town within the Cantons, has its leckerli, a thick kind of parliament—I mean a cake, not an assembly of presumed wise men; and in every town I passed through there was some notable eatable, until I escaped through the last municipality, Geneva, without being made dyspeptic by its gingerbread.

The Pear trees are next predominant in numbers, for their fruit, as I have already mentioned, is cut into halves, dried, and consumed largely in winter. It was too early in the summer for me to ascertain the chief varieties cultivated, but ripe Little Muscats were then (the first half of July) plentiful in the markets. The Cherries—Bigarreaus, Black Hearts, and a red Flemish, were also very abundant, selling retail at the rate of 2½ lbs. for 4*d*. Walnut trees are numerous everywhere, but Apple trees are scant, and Plum trees still more rare. Bilberries and Alpine Strawberries were plentiful in the markets, and by the road sides where shaded by trees. Of kitchen vegetables there were abundance of all kinds common in our markets, and the only peculiarity I noticed was that more white Carrots were offered for sale than those that are red-rooted. Of Peas, also, there was a prevalence of the Sans Parchemin.

Of ornamental trees, the prevalence of the Catalpa is remarkable, and especially for the freedom of its blooming. Tilia microphylla is also quite as much cultivated as is the common Lime, or Linden tree, with us. Its foliage is not so bold, as that of the latter, but its flowers are far more abundant, open earlier, and are more fragrant.

Of the wild flowers I can say but little, for I had to pass rapidly through the districts where the Alpine Flora is richest. Two plants, however, must attract even the notice of eyes looking from the windows of a railway carriage—the red-berried Elder (Sambucus racemosa), and the Yellow Foxglove (Digitalis lutea). Why are they not more cultivated in England? They are very ornamental. Then the Campanulas are strikingly numerous. There are thirteen species in the vicinity of Lucerne, ranging from the C. pusilla, barely an inch high, to the C. pyramidalis, which is 4 feet. All I saw impressed me with the opinion that they were deeper in colour and larger in flower than the same species which I had seen in other European countries, and I find the same observation made by the Rev. Mr. Macmillan:—"The flower that touched me most was our own beloved 'Scottish Blue-bell.' I was surprised and delighted beyond measure to see it hanging its rich peal of bells in myriads from the crevices of the rocks around, swaying with every breeze. It told in fairy tones the music of 'Home, sweet Home.' It was like meeting a friend in a far country. It was the old familiar Blue-bell, but it was changed in some respects. Its blossom was far larger, and of a deep purple tinge, instead of the clear pale blue colour which it has in this country. It afforded a striking example of the changes which the same plant undergoes when placed in different circumstances. I could see in its altered features modifications to suit a higher altitude and a severer climate. In the Alps all the plants have blossoms remarkably large in proportion to their foliage, and their colours are unusually intensified, in order that they may get all the advantage of the brief but ardent sunshine, so as to ripen their seed as rapidly as possible."

And having thus quoted his charming book, I will further extract from it a passage to compensate my own Alpine botanical shortcomings, and will add the recommendation to the reader to purchase the volume, for it is most excellent.

"The Alpine Forget-me-not, only found in this country on the summits of the Breadalbane mountains, cheered me with its bright blue eyes everywhere; while the 'Alpine Lady's Mantle' spread its grey satiny leaves, along with the Arctic Willow, the favourite food of the chamois, over the stony knolls, as if in pity for their nakedness. I found a few specimens of the beautiful lilac Soldanella alpina, and also several tufts of the glacier Ranunculus, on a kind of morain at the foot of a hardened snow-wreath. The Ranunculus was higher up, and grew on the loose *débris*, without a particle of verdure

around it. It seemed like the last effort of expiring nature to fringe the limit of eternal snow with life.

"On this hill [Mont Chenaletta], composed of very friable schistose rock, I gathered a considerable number of very interesting plants peculiar to the Alps. The Arnica montana displayed its large yellow composite flowers in the shady recesses of the rocks; and, as if to illustrate the proverb that the antidote is ever beside the evil, I found its juicy stems very serviceable in healing a bruise on the leg which I got from a falling stone when gathering specimens. Another composite plant, the Chrysanthemum alpinum, whitened in thousands the slopes of *débris*. It has been observed, with Phyteuma pauciflora, beside the Lys glacier on Monte Rosa, at 11,352 feet. Nothing could exceed the beauty and luxuriance of the patches of Linaria alpina, covered with a profusion of orange and purple labiate blossoms, which spread everywhere over the loose soil. No less striking were the sheets of Forget-me-not-like flowers, blue as the sky itself, produced by the Eritrichium nanum, growing in the moist sunny fissures. At the base of the hill on the Italian side, where there was a slight tinge of grassy verdure, the yellow Star of Bethlehem (Ornithogalum fistulosum) and the Nigritella angustifolia struggled into existence. The former rises an inch or two above the soil, and produces two or three brilliantly-yellow flowers on each stem; while the compact showy heads of deep blackish crimson flowers of the latter, springing from very short and very narrow leaves, diffuse a fine vanilla-like fragrance. At lower elevations they grow in great profusion, and form the finest ornaments of the Alpine pastures. Among the Saxifrages which I observed growing more or less plentifully were the S. androsacea (of which I could get no specimen perfect, for the marmot is so fond of it that it nibbles its stems, leaves, and flowers all round), the S. bryoides, Aizoon, biflora, cæsia, and muscoides. A short distance below the summit there were several large snow-wreaths. Their perpetual drip nourished a glowing little colony of the unrivalled Gentiana bavarica, and the compact sheets of the Androsace glacialis, sprinkled over with bright pink solitary flowers. In one place there was a curious natural conservatory. The under surface of the snow having been melted by the warmth of the soil—which in Alpine regions is always markedly higher than that of the air—was not in contact with it. A snowy vault was thus formed, glazed on the top with thin plates of transparent ice; and here grew a most lovely cushion of the Aretia helvetica, covered with hundreds of its delicate rosy flowers, like a miniature Hydrangea blossom. The dark colour of the soil favoured the absorption of heat; and, prisoned in its crystal cave, this little fairy grew and blossomed securely from the very heart of winter, the unfavourable circumstances around all seeming so many ministers of good, increasing its strength and enhancing its loveliness."—G.

ROYAL HORTICULTURAL SOCIETY.

AUGUST 3RD.

FRUIT COMMITTEE.—George F. Wilson, Esq., F.R.S., in the chair. Prizes were offered at this meeting for Peaches and Nectarines grown under glass. The first class was for the best dish of Peaches grown in pots. Mr. Douglas, gardener to F. Whitbourne, Esq., Lexford Hall, Ilford, sent a fine dish of Royal George, and well ripened; and as this was the only exhibition, it was awarded the first prize, to which it was well entitled. The second class was for a single dish of Peaches grown on planted-out trees under glass. Mr. Tillery, of Welbeck, sent Early Grosse Mignonne; Mr. Turner, of Slough, Violette Hâtive, and Mr. Beach, of Kingswood Warren, Epsom, sent a variety without a name. The first prize was awarded to Mr. Tillery, and the second to Mr. Turner. Class 3 was for a single dish of Nectarines grown in a pot under glass. Mr. Douglas and Mr. Tillery were again the competitors. The first prize was given to Mr. Tillery for Elruge, misnamed Murrey, and the second to Mr. Douglas for Rivers' Orange. In Class 4, for Nectarines from trees planted-out under glass, there was no competition. In Class 5, for the best collection of Peaches and Nectarines, Mr. Douglas sent five very fine dishes of Peaches, and six of Nectarines, and these received the first prize. Mr. Earley, of Digswell, exhibited a dish of Moorpark Apricots from the open wall, the flavour of which was exquisite, being perfectly ripened all round.

Mr. Turner, of Slough, sent a dish of very handsome fruit of Bigarreau Napoléon Cherries. Messrs. Bell & Thorpe, of Stratford-on-Avon, sent a seedling Bigarreau Cherry raised by Mr. Haydon, but it does not possess any merit superior to others in cultivation. Mr. Rivers, of Sawbridgeworth, sent fruit of Late Purple Guigne and Noir de Germersdorf; the former a rather hard-fleshed Cherry, and the latter delicious and melting. Mr. Rivers also sent Florence and Bigarreau Napoléon. Mr. Rivers sent fruit of a seedling Plum raised from Brahy's Green Gage crossed with July Green Gage. It is larger than the Early Rivers (Early Prolific), and with a well-marked flavour of the Green Gage. It was remarked by the Committee that this, if an early Plum, will be a valuable addition to our collections. It is remarkable that by the crossing of these two round green Plums the result should be an oval purple one. Another interesting exhibition from Mr. Rivers was a collection of twelve little Apple trees, not a yard high, laden with fruit, which were packed as closely as Onions on a rope. These trees were produced by being grafted on the Nonesuch stock, largely used by Mr. Rivers for the purpose of dwarfing the Apple, and its adaptation for the purpose is proved by the result. G. T. Davey, Esq., Colston Bassett, Bingham, Notts, received a special certificate for two good bunches of Muscat Champion, unusually well coloured.

A special certificate was awarded to Mr. McIndoe, gardener to the Archbishop of York, for remarkably well-grown specimens of Muscat St. Laurent. These were fully 8 inches long in the bunches, which is double the size to which this variety is usually grown, and the plant was grown in the pot with fifteen bunches.

G. F. Wilson, Esq., exhibited excellent fruit of Beurré Giffard Pear, ripened on pot trees turned out in the open ground. They were rich in flavour. Mr. Cooling, of Broad Street, Bath, sent fruit of Brailbrook Seedling Apple, but it was not ripe. Mr. Sidney Ford, Leonardslee, Horsham, sent a fine dish of Knight's Long-bunched Red Currants. Mr. George Lee, of Clevedon, sent branches laden with fruit of a seedling Black Currant, and a dish of bunches. The Committee approved so highly of this Currant that they named it Lee's Prolific Black, and awarded it a first-class certificate. The merit of this variety is its great fertility, the branches being thickly set with large bunches of very large berries; the firmness with which the berries adhere to the stalks, a tolerably violent shaking having failed to remove them; and the unusual mildness and richness of flavour. This is, without doubt, the finest-flavoured of any of the varieties of Black Currant, and may be used as a dessert fruit. Mr. Turner, of Slough, received a special certificate for a collection of Potatoes; and Messrs. Bell & Thorpe, of Stratford-on-Avon, exhibited a collection of seedling Potatoes, of which the Committee could not form an opinion without having tried them.

Plant labels were exhibited from Messrs. Maw & Sons, Benthall Works, Broseley, Salop, improved by leaving out the name of the firm, the lettering of which formerly took up one side of the label.

FLORAL COMMITTEE.—Rev. J. Dix in the chair. Messrs. Jackson, of Kingston, exhibited a fine specimen of Allamanda Hendersoni, which was awarded a special certificate. This specimen completely sets at rest the vexed question of A. Wardleana, which specific name the Committee now ignore. The same firm sent six fine specimens of Erica, which received a special certificate. Mr. Bull sent a specimen of Odontoglossum Schlieperianum, for which a second class certificate was awarded; Calamus intermedius, which had a first-class certificate; Colens atropurpureus, &c.

Messrs. A. Henderson, of Pine Apple Place, sent Allium acuminatum, an old plant; Triteleia laxa, likewise old. From Mr. R. Debron came a variety of Lilium auratum. Mr. Dawson, The Cedars, Chiswick, sent seedling Nosegay Pelargoniums Elizabeth, and Chiswick Beauty, a Silver Bicolor. Mr. Reid, Sydenham Hill, sent Nosegay Pelargonium Mrs. Reid; Mr. T. Ford, Hersham, seedling Zonal Pelargoniums Sussex Rival and Orange Boven, far behind the flowers of this class.

Messrs. Chater sent nine spikes of seedling Hollyhocks; Constance, Walden Queen, Carus Chater, and Leah, received first-class certificates; three cut blooms of Juno, a first-class certificate. A special certificate was awarded for two beautiful boxes of cut flowers. Messrs. Chater's flowers were all good and up to the mark, but required novelty, which we believe is difficult to be obtained in Hollyhocks as well as many other flowers. It will be a new era for the florist to be introduced to a sensation flower. Mr. C. J. Perry sent seedling Verbenas. Here, again, we have nothing strikingly or distinctively new. They were R. H. Vertegans, dark purple; Thos. Hyatt, shaded red; Joseph Sanders, bright scarlet; Rev. J. Dix, pale blush with intense dark eye. Each received a first-class certificate. Messrs. Bell & Thorpe sent Tricolor Pelargonium Macbeth, which, being very distinct, received a first-class certificate. Among a box of cut Petunia flowers, Single Beauty, a distinct variety, was awarded a first-class certificate.

Messrs. Veitch received a first-class certificate for a new distinct Dieffenbachia, and a special certificate for a very beautiful collection of plants.

Mr. J. Hally, Blackheath, exhibited a double rose-coloured Pelargonium called Mrs. Hally, far inferior to Marie Lemoine. Mr. H. Tirebuck, Luton, sent seedling Nosegay Pelargoniums Mrs. Fish, Mrs. Amee, Miss Sowerby, Madam Grisi, and Gustave de Rothschild, a pink full-trussed variety, which last received a first-class certificate as being promising for bedding purposes. He also sent Empress, silver-variegated. From Mr. Eckford, gardener to the Earl of Radnor, came Zonal Pelargonium Coleshill, bright scarlet, which received a first-class certificate. He also exhibited a seedling Ivy-leaved called Lady Edith, a pretty rose-coloured flower, but not equal to Mr. Wills's variety. Mr. Groom, of Ipswich, sent white Zonal Mr. Sach,

a nice flower but with a small truss, thought not equal to older white varieties.

Messrs. Smith, Dalwich, contributed a collection of Balsams, for which they received a special certificate. These were not equal to collections sent in former years; they had not the refined quality. Is it that they are wearing out, and require a change of soil and atmosphere?

Mr. Lawrence, gardener to the Bishop of Winchester, received a special certificate for two fine specimen Orchids—viz., Dendrochilum filiforme and Epidendrum radiatum. Messrs. E. G. Henderson, of Wellington Road, sent Cattleya El Dorado, Amaryllis reticulata, Gnaphalium tomentosum, and Achyrocline Sandersoni. From Mr. Kinghorn came a dark-banded variety of Lilium auratum; and from Mr. W. Earley, gardener to F. Pryor, Esq., Digswell, cut specimens of the beautiful Passiflora Belloti. Mr. Green, gardener to W. W. Saunders, Esq., exhibited a novel and curious form of Orchid, Trichotosia ferox. A first-class certificate was awarded this specimen as an interesting botanic specimen, and not for its beauty. In the same collection as this were Myanthus species nova, Catasetum tridentatum, and a new species of Dieffenbachia from Brazil, which received a first-class certificate.

Mr. G. Smith, of Hornsey Road, was awarded two first-class certificates for seedling Hybrid Nosegays Soleil and Claudius, the latter producing the finest globular truss of flowers yet seen. Both varieties are of the highest merit. Mr. Smith seems to have hit upon a very distinct strain of Hybrid Nosegays. Le Grand, Eclat, &c., have proved themselves this season most valuable.

Mr. Pilcher, gardener to S. Rucker, Esq., exhibited a most exquisite specimen of Hæmanthus cinnabarinus, its globular truss of orange-coloured flowers was much admired—first-class certificate. Mr. T. Howlett, Oxford, sent a very beautiful form of Athyrium Filix-fœmina—kallothrix. So delicate are the pinnules, that the plant reminded us of a Todea; it is a seedling variety from Athyrium F.f. plumosum. A first-class certificate was awarded it. Mr. B. Porter sent seedling Pentstemons, in no way distinct or new. Messrs. Standish & Co. sent specimens of their distinct Todeas pellucida compacta, which had received an award on a previous occasion. Mr. Ware, of Tottenham, sent a golden variety of Lysimachia nummularia, and G. F. Wilson, Esq., specimens of Lilium auratum, with an extra number of petals, stamens, &c., as a botanical curiosity.

General Meeting.—G. F. Wilson, Esq., F.R.S., in the chair. After the election of two new Fellows, and the announcement of the Committee awards, the Rev. M. J. Berkeley, in commenting on the most prominent of the subjects exhibited, directed attention in the first place to Triteleia laxa, which, he said, he at first thought the same as Brodiæa grandiflora, but he found that in the latter there were three perfect stamens, in the Triteleia six. Cyclobothra, a genus of plants which Mr. Wilson Saunders had lately brought under the Society's notice, was next referred to as being well worthy of reimportation, though rather difficult of cultivation, on which account a fine collection which he had seen thirty years ago had been lost. Brownea grandiceps, of which Mr. Bull exhibited a specimen, though handsome in leaf, was stated to be still more remarkable when in flower, and Mr. Berkeley said a plant of it in Flintshire had attained such dimensions, that the house in which it was growing had three times to be raised. Leea excelsa was then noticed, as being nearly related to the Vine, and it was remarked that the genus was named in honour of Mr. Lee, the author of an old work on botany, and grandfather, the speaker believed, of Messrs. Lee, of Hammersmith. Dendrochilum filiforme and Epidendrum radiatum, from the Bishop of Winchester's gardener, were noticed as the most remarkable specimen Orchids shown, and the former was said to have as many as 10,000 flowers. Another was Odontoglossum Schlieperianum; while perhaps the most curious of all was Trichotosia ferox, from Mr. Wilson Saunders, which had never flowered before in this country, though other plants existed. After referring to Athyrium Filix-fœmina kallothrix as being a remarkably elegant variety of the Lady Fern, and more like a Todea than an Athyrium, Mr. Berkeley drew attention to an insect Mr. Bateman had brought him, and which was a thing of great beauty, the eggs being borne on slender stems. It was a species of Hemerobius, which he had more than twenty times received as a Fungus, and which had actually been described by Corda as such. Mr. Berkeley then stated that the seeds of a Gherkin distributed by the Society were those of Cucumis prophetarum, which, along with flowers and pieces of the fruit of the Papaw, is found in West Indian pickles. Mention was next made of a variety of Cichorium Intybus, raised by Mr. Earley, of Digswell, and which, though it had white flowers, all the seedlings from it, numbering two hundred, had, without exception, the ordinary blue flowers. A tree at Chiswick, of which Mr. Berkeley produced a specimen, was stated to be Pterocarya caucasica, known also by several other names, a near relation of the Walnuts, and though it had been said to be extremely tender, it had proved hardy at Chiswick. A number of monstrosities were then shown and commented upon. Among them was a white Lily, each flower forming a spike consisting of a number of bracts. Another case was a Balsam, in which an immense development of coloured leaves had given it the form of a Carnation; another instance was an Allium, in which bulbs had taken the place of what ought to have been flowers; and, lastly, there was a bunch of Grapes which had become, stalk and all, transformed into a fleshy mass.

The next meeting will be held on the 17th inst.

THE ROYAL HORTICULTURAL SOCIETY'S ARRANGEMENTS FOR 1870.

We need hardly say that the Council of the Royal Horticultural Society have done well to make this timely announcement of the Shows to be held next year. The fault in past years has generally been that schedules are issued too late, and the public have not the necessary time allowed them between the appearance of the schedule and the holding of the shows to make the requisite preparations. Plants are not like easily-manufactured articles, that can be produced in exhibiting form off-hand, and in most cases more than one season is required to enable the exhibitor to show them with any prospect of success.

It will be seen from what follows, that all the meetings of next year will be held on Wednesdays. These will be, in fact, the present Tuesday meetings held a day later in the week, so as to enable the great mass of the upper classes, who keep Wednesday as a holiday in the metropolis, to be present at them. It must be borne in mind that the schedule now announced does not in any way supersede the present Committee meetings, but is rather supplementary to them. The Committee will sit as usual for deliberation and decision on the Wednesdays, and those beautiful exhibitions with which we are now familiar being supplemented by the collections mentioned in the schedule, the Society will be enabled to offer to its Fellows and the public attractions such as they have never before been accustomed to. The present announcement being merely general, as indicating the classes of subjects that will be exhibited, the details as to the subjects and the amount of prizes offered will be given shortly.

It will be observed that there is no mention here of a "grand show." "Grand shows" have been found by long and painful experience to be synonymous with grand financial failures, and no society, any more than individuals, is justified in pursuing a course the end of which is ruin. We commend the Council for having taken this bold step, and having asserted the principle of honesty over generosity. There is no limit now-a-days to "grand" undertakings, and grand shows are no exception. Our notion is, that he who would attempt to satisfy the human mind by his own conception of grandeur will signally fail. There is nothing material too great or grand for the human mind to compass, and, when once compassed, then begins the thirst for something grander still. Witness our grand concerts, with their thousands of singing men and singing women. How much more numerous must they become before the cravings of "the public" are satisfied? Our grand organs, which have grown so big there is nobody big enough to blow the bellows, which must now be done by steam—how much "grander" must they become before the public will be satisfied with them? It is so with everything else in the present day which attempts to gratify the public craving; and, therefore, we believe the Council are right in deviating from that course, and adopting one which, from the beauty rather than the grandeur of their shows, will be a great source of attraction.

There are other advantages of a personal kind to exhibitors which make this new arrangement acceptable. One is, the great saving of time which will be effected. There will be only the number of days hitherto given to the meetings of committees to be provided for; and all those extras in the form of spring shows, special shows, and great shows, will be dispensed with.

January 19th.—Forced Flowers—Kitchen Apples and Pears.
February 16th.—Chinese Primroses—Dessert Apples and Pears.
March 2nd.—Hyacinths, Tulips—Apples, Pears, Early and Late Grapes.
March 16th.—Cyclamens—Apples and Pears.
April 6th.—Camelliss—Cucumbers and Forced Salads.
April 20th.—Pot Roses—Forced Vegetables.
May 4th.—Azaleas—Forced Fruits.
May 18th.—Pelargoniums—Forced Strawberries.
June 1st.—Rhododendrons—Forced Peaches and Nectarines.
June 15th.—Orchids—Strawberries.
July 6th.—Rose Show.—Pine Apples.
July 20th.—Picotees, Carnations, and Pinks—Cherries and Currants.

August 3rd.—Hollyhocks—Early Peaches, Plums, and Gooseberries.
August 17th.—Gladiolus—Peaches and Nectarines.
September 7th.—Dahlias—Plums and Figs.
September 21st.—China Asters—Early Apples and Pears.
October 5th.—Fuchsias—Grapes.
November 2nd.—Chrysanthemums—Pears.
December 7th.—Late Chrysanthemums—Dessert Apples and Pears.

POTATOES SUPERTUBERATING.

Many sorts of my round Potatoes, which are yet green in their foliage, are beginning to supertuberate. Kidneys, with their foliage green, do not show the unfortunate symptom so badly. I am taking up both sorts that give signs of it. I advise my readers to follow my example at once; if not, to allow their Potatoes to remain in the soil till the latest period possible, in order that the tubers may throw out as many young ones as possible; then, at taking-up, to sort away the older run-out tubers, and boil them down at once for the pigs with a little salt, and to keep the supertubers only for eating and for seed. I follow the plan of taking up those sorts which run-out the moment they show signs of doing so, if they have attained a fair size, and I crop the ground at once with Turnips or with winter and spring Cabbages. If the Potatoes are kept spread out in a dry dark place, they will considerably increase in the ripening process.—Upwards and Onwards.

THE SCOTCH LABURNUM.

"A Wanderer" sends the Editors a photograph of a grand old Scotch Laburnum, and would like to know why this valuable tree is so seldom to be met with about gentlemen's seats? If strength, symmetry, and grace, combined with beauty of foliage and gorgeousness of flowers is a recommendation, this tree is possessed of all; while in a commercial point of view the value of its timber is second to none. Amid the "rage" for new and rare plants, might you not have a word to say in behalf of this and other good old native plants?

[The photograph sent by our correspondent is conclusive evidence that the tree, which is growing in a garden at Coldstream, N.B., is all that he tells of it. The height of the tree is 36 feet; the extreme breadth of the top, 44 feet; the girth of trunk, 10 feet; and of the three primary limbs, 6 feet each.

The Scotch Laburnum is usually considered a variety of the Cytisus Laburnum, but we rather agree with those botanists who consider it a species, and have named it Cytisus alpinus. Dr. Hogg, in his "Vegetable Kingdom," says, "It is by far the finer one of the two; its leaves are large and glossy, and its flowers are of a darker yellow colour, and are produced in considerably longer racemes than the English variety—it also blooms later. Like much that is beautiful in this world, the Laburnum, too, conceals dangerous and deadly properties. The seeds are violently purgative, emetic, and decidedly poisonous, and should never be allowed within the reach of children or cattle. To prevent accidents, we would recommend that, whenever the tree has done blooming, and the pods formed, they should be immediately removed. The wood is much valued for cabinet-work, inlaying, and turnery-ware. It is hard, and so heavy that it will sink in water; of a fine colour, and receives an excellent polish. In France it is called ebony of the Alps. It is used for making handles to knives and surgeons' instruments; and in Scotland the bickers, luggies, or noggins, are made with alternate staves of Laburnum, Holly, or Spindle-tree, the dark-coloured being the Laburnum. It is also used for musical instruments, flutes, punch-bowl ladles, and several other fancy articles. Hares and rabbits are extremely fond of this tree, which they frequently injure very seriously by eating the bark, and the seeds are frequently sown in plantations, because they will touch no other tree so long as they can get a supply of Laburnum; and though the plants may be eaten to the ground every winter, they will spring again next season, and yield a regular supply of winter food for these animals."

Philip Miller is loud in its praise, and remarks—"In England there are few of these trees which have been suffered to stand long enough to arrive to any considerable size, for as they have been only considered as ornamental, the frequent alterations which most of the gardens in England have undergone, have occasioned their being rooted-out wherever they were growing; but in some of the old gardens in Scotland, where they have been permitted to stand, there are large trees of this kind, which are fit to cut down for the use of the timber. I have seen two old trees of it in gardens, which were more than 1 yard in girth at 6 feet from the ground, and these had been broken and abused, otherwise might have been much larger: they grow very fast and are extremely hardy, and, therefore, may be well worth propagating upon poor shallow soils, and in exposed situations. His Grace the Duke of Queensberry sowed a great quantity of the seeds of this tree upon the sides of the downs, at his seat near Amesbury, in Wiltshire, where the situation was very much exposed, and the soil so shallow that few trees would grow there; yet in this place the young trees were 12 feet high in four years' growth, and became a shelter to the other plantations, for which purpose they were designed; but the hares and rabbits being great enemies to these trees, by barking them in winter, they should be fenced from these animals. The wood is of great strength, and is much used for pegs, wedges, musical instruments, handles of knives, and a variety of furniture. Mr. Bontcher mentions that he had seen a large table and a dozen chairs made of it, which judges of elegant furniture thought the finest they had ever seen. Pliny says its wood is the hardest of any, next to ebony. Matthiolus speaks of its being used for making the best bows. It chars remarkably well; and if planted thick to run up tall, it would make durable hop-poles. For this purpose it might be planted in large clumps in parks, where it would be also very ornamental; the branches being generally loaded with long strings of flowers, hanging down from every part of them, in the month of May. Haller observes that the Latin name Laburnum was evidently formed from the alpine name L'Aubours. Formerly it was called in English Bean-Trefoil and Peascod tree, but the Latin name has prevailed over these. In German it is Bohnenbaum, and in French Cytise des Alpes, Aubours, and Faux Ebenier. It is a native of Switzerland, Austria, Provence, &c., and was cultivated here by Gerarde in 1596. Tradescant had both varieties in his garden."]

NOTES AND GLEANINGS.

Her Majesty's Commissioners for the Exhibition of 1851 have announced that the first of a series of Annual International Exhibitions of selected works of fine and industrial art will be opened in London at South Kensington, on Monday the 1st of May, 1871, and be closed on Saturday the 30th of September, 1871. The Exhibitions will take place in permanent buildings, about to be erected, adjoining the arcades of the Royal Horticultural Gardens. The productions of all nations will be admitted, subject to obtaining the certificate of competent judges that they are of sufficient excellence to be worthy of exhibition. They will include objects of the Fine Arts—paintings, sculpture, engravings, &c; scientific inventions and new discoveries of all kinds, manufactures; and in Horticulture, international exhibitions of new and rare plants, and of fruits, vegetables, flowers, and plants showing specialities of cultivation, will be held by the Royal Horticultural Society in conjunction with the above Exhibitions. Special rules for the horticultural exhibitions will be issued by the Royal Horticultural Society. The arrangement of the objects will be according to classes, and not nationalities as in former international exhibitions. One-third portion of the whole available space will be assigned absolutely to foreign exhibitors, who must obtain certificates for the admission of their objects from their respective Governments. Foreign countries will appoint their own judges. The remaining two-thirds of the space will be filled by objects produced either in the United Kingdom, or, if produced abroad, sent direct to the building for inspection and approval of judges selected for the British exhibitors. Objects not accepted for exhibition must be removed according to the notices given, but no objects exhibited can be removed until the close of the Exhibition. All exhibitors or their agents must deliver at the building, into the charge of the proper officers, the objects unpacked and ready for immediate exhibition, and free of all charges for carriage, &c. Her Majesty's Commissioners will find large glass cases, stands, and fittings, free of cost to the exhibitors, and, except in the case of machinery, carry out the arrangement of the objects by their own officers. Her Majesty's Commissioners will take the greatest possible care of all objects, but they will not hold themselves responsible for loss or damage of any kind. Prices may be attached to the objects, and exhibitors will be encouraged to state their prices. Agents will be appointed to attend to the interests of exhibitors. Every object must be accompanied

with a descriptive label, stating the special reason, whether of excellence, novelty, or cheapness, &c., why it is offered for exhibition. There will be no prizes, but a certificate of having obtained the distinction of admission to the Exhibition will be given to each exhibitor. A catalogue will be published in the English language, but every foreign country will be free to publish a catalogue in its own language if thought fit.

—— The preparations for the Hamburg International Exhibition are going on favourably. We have seen a plan of the ground, which is laid out artistically, and we have seen a circular announcing several extra prizes offered by various continental States. Exhibitors have promised to send from England, France, Italy, the Tyrol, Bavaria, and Wurtemburg. Those who require a complete list of the prizes and how they are to be contended for, had better apply to Mr. Eyles, Royal Horticultural Society's Garden, South Kensington.

—— An extensive cultivator and one whose knowledge of these matters we have great confidence in, informs us Gloede's Perpetual Pine Strawberry was this year six days earlier than Black Prince in the same bed. The runners were planted last August. Those planted in May are now in full fruit, and keep on blooming and bearing, showing every indication of continuing so for some time to come.

—— Messrs. Standish & Co., of Ascot, inform us that they have a plant of Lilium auratum, 13 feet high, coming into bloom with *one hundred* flowers upon it. Next week it will be at its best. The treatment required to obtain so great a result is never to disturb the bulbs, but to pot them on without breaking the ball. Never shake them out of the pot. The plant which Messrs. Standish have grown so successfully was originally in a 6-inch pot, and in two years it received two shifts only, the last being into a 16-inch pot. The best soil is leaf mould. In this the plant is found in its natural state in the woods and plantations of Japan.

—— Another veteran patron of horticulture has passed away. Charles B. Warner, Esq., died at Hoddesdon on the 27th of last month. Like his brother, he was especially fond of Orchid culture, and formerly, when Mr. Williams, of Holloway Nursery, was his gardener, exhibited successfully his favourite flowers. Of late years he has reduced his collection, and ceased from exhibiting. He was at one time a member of the Royal Horticultural Society's Council.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Finish planting *Broccoli* and all *Winter Greens* as soon as possible. Make the principal sowing of *Cabbage* for spring use, and plant out those sown last month for Coleworts. Water the late crops of *Celery* in dry weather, and continue to earth-up those in a forward state. Sow *Early Horn Carrot*, to remain in the ground for winter use. Sow Tripoli *Onions*. Any *Potatoes* in which symptoms of disease have appeared should be used first. Sow Brown Cos and hardy Cabbage *Lettuce* for spring use towards the end of the month; plant out those sown last month in a warm situation. These will probably be useful in November. Sow Prickly *Spinach* for winter and spring supply. Sow *Turnips* soon, and make a sowing of Early Dutch at the end of the month for spring.

FRUIT GARDEN.

Proceed with thinning and nailing-in young shoots of all wall trees, if any remain unfinished. Peach trees in particular should now be kept closely nailed-in, so that the wood may ripen; and in order that the fruit may have the advantage of light and air, remove a portion of the leaves where the fruit is too much shaded, and at the same time pull out any nails that are likely to come in contact with it. If the weather is dry before the crop ripens, give the border a good watering. Wash the trees occasionally, and trap earwigs. Perhaps the easiest way to free the trees of them is to place short pieces of bean-stalks or other hollow stems in different parts of the trees, and look them over every second day, blowing the contents into a bottle and replacing the tubes as before. As soon as the crop of Strawberries is gathered, go over the beds and cut away all runners; fork the soil about the plants to encourage them to make good growth before the season is too far advanced. Layer runners for new plantations. Use the garden-engine occasionally in warm weather to keep down red spider.

FLOWER GARDEN.

Now that the effect of the present arrangement of colours in beds can be fairly seen, there is an excellent opportunity for noticing any mistakes and determining upon the arrangement next season, and this should be done without delay. When it is decided what each bed is to be occupied with next season, a plan of the garden should be made, writing the names of the plants for the beds according to the arrangement decided upon. This will be of the greatest service in showing at any time what quantity of each kind of plant has to be propagated, and where some method of this sort is not adopted, it is not unusual to find at planting-out time that there is a scarcity of some plants, and too many of others, whereas those who have their plan to refer to, can tell at a glance the exact number of any plant required, and thereby avoid mistakes. Dahlias are now growing very rapidly, and will require to be examined frequently to keep the side branches securely tied-in, for when left untied they are easily broken off by a thunder shower. Hollyhocks must also be securely tied to their stakes. Continue to remove dead flowers from Roses, and give plenty of manure water to the autumn-blooming varieties. Plant out rooted cuttings of Pansies in nursery beds in a shady situation, keeping them well watered in dry weather. Finish budding Roses, and take care that Carnations and Picotees do not suffer from drought. Cross-breed flowers which have the desired properties. The operation is interesting, and is attended with little difficulty. Mark seedlings which promise well, and pull up those which are not up to the standard. Plant out Pink-pipings and put in a second crop of cuttings, these will often strike root and make better plants than the early ones. Look over Tulips, and divest the bulbs of their loose skins. Arrange the rows of the bed so as to be ready for planting. Discard all impure flowers, whether stained in the base or on the stamens, as whatever good qualities a flower may possess, these defects render it utterly worthless.

GREENHOUSE AND CONSERVATORY.

Now that there is a profusion of flowers out of doors, it will not be possible to maintain the interest of the conservatory, except by keeping it furnished with handsome specimens of showy plants in first-rate condition, and with proper convenience this is no difficult matter. Nothing, therefore, should be brought here that is not well bloomed, nor should a single plant be allowed to remain a day after it begins to grow shabby, for it is bad management to occupy glass structures with plants inferior to those which are plentiful in the open air. It is not desirable, however, to crowd the house with flowering plants; the aim should be to have a moderate number of handsome specimens effectively arranged, which will be far more interesting than a larger amount of floral display from plants of no individual merit. It is also advisable to allow the plants plenty of room on account of the permanent occupants of the beds or borders, which at this season should not be crowded, in order to secure well-ripened wood; for unless this be obtained they will not bloom finely. Use every means to keep insects in check, and let order and neatness be everywhere apparent. Azaleas, which do not seem inclined to start into growth freely, should, if possible, be placed in a moist situation, and receive every possible attention to induce them to make vigorous growth. Specimens in heat, which have their bloom-buds well formed, should be removed to a cool house or a sheltered shady situation out of doors; but they must be protected from drenching rains. Young plants of kinds which it is desirable to grow as large as possible, if they are setting for bloom, should be stopped regularly, and be encouraged to make another growth. See that the whole stock, particularly plants in heat, are free from black thrips, and spare no trouble to keep the plants clear of this pest. Camellias which have fairly formed their bloom buds, should be either placed out of doors, or in a cool dry house, keeping them rather dry at the root in order to prevent their making a second growth, which young vigorous plants are apt to do if kept in a close, moist situation after they have formed their flower-buds. Any of the plants which may require more pot room, should be repotted at once, so that the roots may take hold of the fresh soil before the blooming season; for they seldom bloom finely unless the pots are moderately filled with roots. If there are sickly or badly rooted specimens of other plants, they must be frequently examined for red spider, otherwise they may become a harbour for that pest, as it will soon spread to adjoining plants. See that young stock is not allowed to suffer from want of pot room, and attend carefully to watering, giving weak liquid manure to all plants in free growth that are likely to be benefited by it. Attend well to young stock, which will now be growing freely. Keep the shoots regulated as may be necessary to secure well-formed specimens, and use every care to

afford a moist atmosphere, sprinkling them overhead early on the afternoons of bright days, and reducing the amount of air.

STOVE.

Such of the inmates as are intended for the decoration of the conservatory in autumn and early in winter, should be carefully looked over, shifting any that are likely to want more pot room, so as to have the pots well filled with roots before the flowering season. Maintain a moist atmosphere, and ply the syringe vigorously upon any plant infested with the red spider. With respect to Orchids, encourage any backward plants with plenty of heat and moisture, while this can be safely done. See that plants on blocks and in baskets are properly supplied with moisture at the roots. Syringe lightly morning and evening, and sprinkle the floors, &c., frequently, so as to keep the atmosphere moist.—W. Keane.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

At last, on the 28th ult., we had a refreshing rain, not enough to penetrate deeply, but enough to cool and refresh the whole of vegetation on which it fell, and no doubt it would have gone deeper if the surface soil had not been so warm and dry. It has had a magical effect on some rows of Peas and Cauliflower which had been previously watered with sewage, and but for the rain we would have followed the latter application with a little clean water to make all sure. It is rarely at this season, unless in a thunderstorm, that there is a sufficient downpour to sink very deeply into parched soil; and therefore it is a good method where water is at command, to water pretty well before some drizzling showers come, as then we receive the benefit of the cool shady atmosphere. Watering in bright sunshine is only defensible when we cannot do otherwise, and then the water will soon evaporate if means be not taken to prevent its rising by mulching or surface-stirring. The great advantage of the natural watering over artificial is, that it is generally accompanied with a clouded sky, and every part of a plant—stem and leaves—is refreshed as well as the roots.

We have seen no signs of fly or blight on vegetables, but we are sorry to learn that fields of Peas and Beans have had to be out and used for little better than manure, owing to having been crusted with the fly. The recent showers—and much more abundant in the valleys round here than with us, would do much to mitigate if not remove this evil.

All crops planted out have been much refreshed, and promise to grow freely, but we have planted out little more than what was recently referred to, as on removing early Peas, &c., the ground was more like ashes under a grate than common garden soil, and planting would be of little use without a copious watering. Unless more moisture comes we shall plant freely in temporary beds, as this will enable us to economise watering. We have turned the ground occupied by early Cauliflowers into wide Celery beds holding four rows across, and planted it at once, as the moist dung tended to make up for the dryness of the soil; but the dryness did surprise us, as the fine Cauliflowers had frequently been watered, and well mulched too. The dryness of such ground must have been owing to the amount of moisture evaporated from the large spreading leaves. In digging out the Celery trenches we found that the roots had gone deep in search of the necessary moisture.

The rains and the cooler atmosphere will be of great benefit to Turnips, especially young ones, which could scarcely hold their own. When the foliage begins to cover the ground well, and the land has been well cultivated, the plants are almost independent and able to look after themselves.

Our cottagers and allotment-holders should bear in mind, that as Potatoes, &c., are cleared off, it is a good time to sow *Turnips* to come in during the winter and spring The White Dutch, the Red Stone, the American Red-top, or Purple-top rather, the Flat White Turnip, and the Strap-leaved, are the best for this purpose. Those who grow and cook for themselves should not pass over the Yellow Maltese, but it is rarely that others than Whites are cooked in gentlemen's establishments; but what can be nicer than a crisp young Swede well boiled and mashed?

A few words more about *Potatoes*. From the earliest-raised, especially if the tubers were a little greened by exposure, it is not too late to plant in a warm border, so as to raise new Potatoes in November and December. Of course these will be waxy, but they may be kept over the winter bedded and mixed with earth. The Potatoes, especially all the earliest ones, have been good this season. We planted a few rather late, and wish we had not done so, as they will be rather in our way. These threw up a number of small shoots instead of one or two strong ones, and though we thinned the shoots considerably, the produce will be later than we wanted them to be. We have frequently intended to give a warning against the too frequent use of very early waxy Potatoes. Using a few is a very different affair from making such watery waxy Potatoes the chief part of a meal. We have not much medical authority, but considerable observation for the statement, that when cottagers from hard times, &c., have been driven very early to their Potato plots, sickness, low fever, and diarrhœa were the frequent consequences. We know that it is the starch and flour, and not the mere fibrine of the Potato that are chiefly nourishing, and these are not much secreted when the tuber is but young. Like most of the plants from which we procure our sago, arrowroot, &c., the Potato belongs to a poisonous family. We have had it on the authority of cattle-feeders that Potato tops did more harm than good. Water in which Potatoes were boiled did anything but good to pigs, to which it was given. There are few of us who at some time have not luxuriated in Irish stew, but there are few who have not known something of heartburn when the stew was made in the usual way—Potatoes, meat, &c., boiled in the same liquid. These effects are avoided when the Potatoes are nearly boiled in separate water before they become a constituent part of the stew. Our cottage reader may depend on this, that if he boil his Potatoes without breaking them—that is, if the water come away clear from them, such water will be injurious rather than otherwise to his pig if he keeps one.

We have several times alluded to the *earthing and non-earthing-up* of Potatoes, dwelling on the importance of the former operation, only when the tubers were so shallow as to be likely to be greened by exposure to the air. We believe greening is very good, so far as preserving tubers for planting is considered, and their future vigour of growth; but we well know that greened Potatoes were unpleasant for use, and always suspected they would be dangerous. We notice that M. Chatel, the great French agriculturist, says, that in this greened state the Potato contains a peculiar substance, called solanine, which if absorbed in large quantities is a dangerous poison, and which becomes more abundant as fermentation advances. When we see at the vegetable stores of Paris, and elsewhere, Potatoes grown more or less green under the action of the light, we ask how it is that the officers of public health do not forbid their sale. Of how many colics, diarrhœa, &c., must they have been the unsuspected causes? M. Chatel, therefore, strongly recommends that Potatoes designed for food should be kept constantly in the dark. We have not a doubt that if partaken of, greened Potatoes are not only unpleasant, but dangerous.

FRUIT GARDEN.

The dry weather has made our Strawberry season a short one. As we write the produce is becoming small. By layering and potting, we are preparing for future forcing. A good part of our trees have had their summer pinching and pruning, and would have all been attended to sooner, but for a press of other matters not entirely connected with the garden. Gave a good watering to trees in the orchard house now yielding some fruit. In the Peach house we have a tree of the Walburton Admirable, which has kept us in some measure in a succession of Peaches. In other fruit houses, air-giving in this hot weather, and damping the paths and floors, have been the principal work. Melons, on the whole, have been good; in the very hot days some were all the better of a piece of paper suspended over them. The rains have pretty well cleared the Currants that remained and had been troubled with honeydew.

ORNAMENTAL DEPARTMENT.

A very busy week in putting lawns and walks in first-rate order after the rain. The walks treated as lately described will now be firm and clean for months; and where we could not with propriety machine or mow the lawn we cleared off anything in the way of Plantains, Daisies, &c., with the Daisy-knife. The lawn is still greenish and considerably refreshed, and has not been brown yet; but, then, it does not have the rich tint of green we like to see, and there are many cases where machining or mowing, however slightly, would tend to make it brown.

The Scarlet Pelargoniums are now very good without any artificial watering, and Calceolarias are still in their glory. With occasional showers we may hope the flower beds will soon do without much attention beyond picking and trimming for the season, as the nights are now becoming longer, and we may

expect the dews to be more genial and heavy. In several mornings both before and after the showers, there was no dew perceptible in the morning, and then plants feel the effects of a scorching day. When plants show a little of the effects of a burning sun, it is not always good policy either to water or to shade, and there is little necessity for either if the plants hold up their heads firmly in the morning. We have been able to make a contrast between beds that could receive but little water, and others where by turning a tap it could be given most liberally, and was so given, but the balance in every case was not in favour of the abundant watering, though we should all like to have the opportunity of using it when we liked.

Much engaged in potting, changing, making preparations for wholesale cutting-making, but the details of some of these must be given hereafter.

Greenhouse plants turned out of doors should be in a shady place at first, and when moved into more sun should have the pots protected from the heat, as that is so apt to scorch the roots.—R. F.

COVENT GARDEN MARKET.—August 4.

Large supplies, the trade heavy for inferior descriptions, and but little alteration in prices. Potatoes are brought in plentifully both by rail and coastwise, good samples realising last week's quotations.

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely to The Editors of the Journal of Horticulture, &c.*, 171, *Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

Collection of Fruits (*X. Y.*).—Five in sixteen is rather over the proportion allowed of six in twenty. Why not ask the Secretary?

Bere Lily (*C.*).—We do not know any plant so named.

Grafting Roses (*S. T. V.*).—"I do not advise root-grafting, or grafting Roses on the Manetti stock out of doors. If your buds have failed, water the stock copiously, scratch away the earth, and bud again as low as you can do on the main stem. Manetti stocks can be budded as late as September, even as late as the bark on the stocks will run.—W. F. Radclyffe."

Wheat Blighted (*F. Manning*).—It is most severely mildewed. We should think it has been laid, and long in contact with the soil. The ears are totally barren.

Grapes Diseased (*Nottinghamensis*).—They are severely affected with the ulceration called by gardeners "the spot." It probably arises from the roots not supplying a sufficiency of sap to sustain the rapid growth. Remove the soil down to the first tier of roots, and replace it with some fresh compost—about equal parts of light loam and cow dung. Water copiously once a-week with weak tepid manure water. Thin out all diseased Grapes, and admit air very freely. (*J. F.*).—Your Grapes are affected both with the spot and rust. Treat the Vines as we have above recommended.

Grapes for Cool Vinery (*C. R. C. D.*).—Early Saumur Frontignan and Meurthe Frontignan have the Muscat flavour. Black Champion, Black Hamburgh, Early White Malvasia, and Royal Muscadine.

Specks on the Footstalks of Grapes (*A. Q.*).—We do not think the white specks on the footstalks are mildew. They will presently become brown as the Grapes advance to maturity. If mildew should appear, dust the parts with flowers of sulphur. You should have sent us a specimen.

Grapes not Stoning (*A. S. A.*).—It is owing to imperfect fertilisation. The atmosphere has been kept too dry when the Vines were in flower. A moist atmosphere should have been maintained by frequently sprinkling the paths, &c., when the Vines were in flower. We do not advise budding a Muscat on the Black Hamburgh, but you may inarch it now, or early next spring graft the Black Hamburgh with the Muscat. We do not think that will enable you to perfect the Muscats in a greenhouse. Why not plant Foster's White Seedling or Buckland Sweetwater? Either is better than the Royal Muscadine, and more suitable for a greenhouse than the Muscats.

Mealy Bug on Grapes (*A Coutlon*).—As the insect has attacked the bunches, your only plan will be to tie the shoulders out, so as to make the bunches as loose and open as possible, and then you may with a small brush remove the insects. It is not only the bug, but the secretion—honeydew, that you will have to clear away, and that may be partly effected with water at a temperature of 120°, applying it with a syringe. To rid yourself of the pest without destroying the bloom, and injuring the fruit to some extent, is out of the question. When the leaves have fallen you may then give everything a thorough cleaning, and had this been done before the Vines were started, and had the plants on the back wall been kept clear of the bug, the present state of the Grapes might have been considerably, if not completely prevented.

Viola cornuta and Arabis Sowing (*Cambria*).—To obtain plants for spring bloom, the seed should be sown in pans early in the preceding year, and placed in a cold frame, where they should remain until the seedlings are well up. Then admit air freely; and when large enough to handle, prick them out in the open ground in good rich light soil, transplanting in autumn to where they are to bloom. The seed should be sown in April or May. The seed of Viola cornuta Purple Queen, and V. luteu, may now be sown, placed in a frame or under a hand-light, and when large enough to handle, the plants may be pricked off in a sheltered situation. They will bloom next season, but not sufficiently early for spring gardening.

American Blight on Apple Trees (*A Subscriber from the Commencement*).—The most effectual mode of freeing the trees is to wash them with water by means of a powerful syringe or engine. The insects will be washed on to the ground, and though incapable of further injury, it is well to remove them with a hoe, hoeing and raking the ground as far as the branches extend. If the roots are attacked, all you can do is to remove the old soil to the extent of 6 or 8 inches, and for 2 or 3 feet from the stem, giving the roots a good washing, and replacing with fresh soil. The soil removed should be burned or taken a considerable distance from the trees. In autumn, after the leaves fall, the trees may be washed with paraffin oil, applying it with a brush to the parts affected.

Sulphur Dissolving (*H. F. H.*).—Probably the receipt you allude to is this:—1 lb. flowers of sulphur, and 1 lb. fresh slaked lime. Place in an iron or glazed earthenware pot containing five pints of water, boil ten minutes, keeping stirred all the time. Allow the whole to settle, and about four pints of the liquid will be available for bottling. One pint of the bottled liquid to twelve gallons of water should be applied with a syringe to plants or fruit trees infested with mildew, making every part thoroughly wet. It may be applied without injury to the foliage and fruit of Vines. A more useful insecticide, but not to be applied to Vines, Melons, nor Cucumbers when in leaf, being one of the best for washing trees in winter as a preventive, and for destroying insects at any time, is as follows:—7 lbs. of sulphur vivum and 7 lbs. of quicklime; boil together for fifteen minutes in three gallons of water, then add 2 lbs. of soft soap and 1 lb. of tobacco, and boil slowly for thirty minutes. Strain and bottle the clear liquid. Apply the liquid with a brush, and undiluted, as a winter dressing to trees at rest. Use one pint to three gallons of wash for fruit trees in leaf, except those previously mentioned, and all plants with soft hairy leaves, whilst those with smooth leaves as the Peach, Gardenia, &c., it will not injure. It is an effective remedy for red spider, thrips, aphis, and mildew. We have used it upwards of twenty years, and it was employed for more than half a century by the gardener who gave us the receipt.

Grafting Lime Trees (*Hibernicus*).—By grafting the upright on the weeping you could not cause the latter to become weeping, and the converse would hold good. We cannot say what the effect would be as regards the plant's constitution. The weeping kind might be invigorated, but that is a matter for experiment.

Pampas Grass (*T. D.*).—Spergula pilifera would answer to place round the Pampas Grass, but as you have a bed 9 feet wide and but one plant in the centre, we would plant four more in the bed, and have a group of the Pampas Grass, especially as it is in the centre of the flower garden. We would do that or allow the Grass to grow to within a foot or so of the stems all round; or you might have an edging to the bed of Festuca glauca, 1 foot from the edge, and an inner band of Dactylis glomerata variegata or elegantissima. Any of these arrangements would be more effective than the Spergula pilifera. Your plant, we should think, will flower finely this autumn.

Japanese Medlar (*C. P.*).—It is Eriobotrya japonica.

Tobacco Water (*A Young Beginner*).—Pour half a gallon of boiling water upon 1 oz. of tobacco. Let it cool, and after straining it may be used for syringing.

Name of Fruits (*A. B.*).—The Morello Cherry.

Names of Plants.—(*Constant Reader*).—We cannot name florists' varieties. They are far too numerous and nearly alike, especially Pelargoniums, Geraniums as you call them.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending August 3rd.

Date.	Barometer.		Thermometer. Air.		Thermometer. Earth.		Wind.	Rain in inches.	General Remarks.

POULTRY, BEE, AND PIGEON CHRONICLE.

THE POULTERS' COMPANY.

(*Concluded from page* 90.)

I did not shout as Pickle's friend did, but when I put the first mouthful of Swan into my mouth I was disposed to cry out, "This bird has eaten nothing but sprats." It had an undeniable flavour of fish beyond any wild fowl I ever tasted. I believe the Corporation of Norwich is bound by charter to consume a certain quantity of corn in fattening Swans, and then they have to be got rid of. If it were a necessity that they should be properly cooked, then the gift of a Swan in England would be like that of a white elephant in India. I believe it should be picked quite clean, and trussed with the feet on. It should be stuffed full of rumpsteak cut in dice, and of fresh butter rolled in small balls, sundry herbs, and a suspicion of garlic or shallot. The entire animal should be wrapped in thin slices of fat bacon, and basted with butter during the hours of roasting. Sauce of spice, port wine, and jelly. Then friends must be asked to partake, and something must be provided in case the Swan should be bad—a costly present. Small marvel that the recipient of one gave it away, and received it again within ten days. There is only one comfort, the victims are generally the Prime Minister, the Commander-in-Chief, or the Foreign Secretary. Some of us are, therefore, likely to be exempt from the gift of a fattened Swan.

The description given of the poulters' arms is incomplete. The crest is a Pelican tearing her breast in order to feed her brood, that are ravenously swallowing her blood; the supporters are also Pelicans; and the motto is "Remember Your Oath."

The bequests of the Company date back to the early part of the seventeenth century. It is among those which supplied King James with money, and thereby gained an interest in the Irish estate. Bishops, knights, and aldermen have figured among their liverymen, even of recent date. I do not know whether it be the same man, but the Campbells are descended from a Norman Campo Bello who married a Scotch heiress. There are still tenures by which estates are held, which consist in the necessity of keeping a large dovecote, stocked with a certain number of Pigeons. One I have been told was left by John of Gaunt on such condition.

Poultry plays a far more important part in feeding a people than is imagined by those who do not study the subject, and it becomes annually larger.

The Company has suffered, like others of the city of London, from the alterstion in the times. Its ranks and funds were both recruited by the members and fees contributed by apprentices. The youth was impressed by the oath-taking before master, wardens, clerk, and court of assistants. He learned the "art and mystery" in exchange for his seven years' services, and at the expiration of the term became free of the Company by "servitude." This tied him to it, and he generally persevered till he became liveryman, assistant, and eventually master. Many old members of the Company were benefactors, some to a large amount, at their decease. It is many years since there was an apprentice bound to the Company, and there appears no probability there will be. I believe the Company is flourishing, and it has the reputation of being one of the best managed in the city. It has no hall. As the lawyer's lady, in "Jack Hinton," said that "but for Oliver Cromwell and the Danes at the battle of the Boyne, she might have been a queen in her own right," even so, we are told there are poulters who believe that but for the fire of London, Leadenhall would still belong to the Company.—B.

HASLINGDEN POULTRY SHOW.

This was a success, the arrangements being far more complete than at the generality of shows, and the only improvement the most critical observer could suggest, would be to place the pens a little higher from the ground for general inspection. The Buff *Cochin* chickens were very meritorious, and mostly composed of very early-hatched chickens. The *Spanish* classes were even more praiseworthy, although many of the adults of this breed were fast falling into moult. The *Hamburghs* were remarkably good, and the Game *Bantams* were of excellent quality, and in great numbers. Cochin Bantams were the recipients of the first prize for any variety of Bantams, and Blacks second.

The class for any variety of *Ducks* was a great feature of the Show. During the forepart of the day (July 29th), the weather was most favourable, but towards the closing time it rained heavily.

The *Rabbits* appeared in goodly numbers considering the small inducement offered, there being only one class. This was a great mistake, when within a dozen miles of the show ground some of the best Rabbits in the country are kept, and perhaps more prizes are received within that area than any other of equal extent. One rabbitry we know can generally number from one to two hundred, consisting of every known variety, and in each variety many prize-winners; so that the Haslingden Committee need not fear Rabbits not being forthcoming, if they will wisely invite their exhibition by proper and numerous classes. Ten entries appeared in the catalogue, but only nine pairs presented themselves—viz., Lop-eared, Himalayan, Angora, and some not perhaps considered of the pure "fancy" variety.

We rather think the Judge leaned to the old favourites the "Lops," as is generally the case when an unfortunate mixture of three or four varieties is found from want of proper classes, and so the more recent and less known, but equally beautiful, varieties appear to possess less merit in his eyes. Mr. Beldon, of Bingley, Yorkshire, was the Judge, and made no doubt as much as possible out of the mixed material at his disposal, but it is to be hoped the Committee will feel justified for the future in offering at least four classes (five are better), and they need not be afraid of the result. The specimens sent were well cared for, but the pens were rather too near the ground for the Rabbits to be seen to advantage.

Cochin-China (Buff or Cinnamon).—1, W. A. Taylor, Manchester (Buff) 2, C. W. Brierley, Middleton. *hc*, W. A. Taylor; J. Sichel; J. Robinson, Garstang. *Chickens.*—1 and Cup, T. Sharples, Forest Bank, near Rawtenstall. 2 and *hc*, C. Sidgwick. *c*, W. A. Taylor; A. Bamford, Tonge, near Middleton (Buff).

Cochin-China (Any other variety).—1, T. Stretch (Partridge). 2, C. W. Brierley. *Chickens.*—1, T. Stretch (Partridge). 2, C. Sidgwick (Partridge).

Brahmas (Dark).—*Chickens.*—1, T. Sharples. 2, T. Pomfret, Hoghton Lane, Preston. *hc*, C. Layland.

Brahmas (Light).—*Chickens.*—1, H. M. Maynard, Holmewood, Ryde, Isle of Wight. 2, H. Dowsett, Pleshey. *hc*, H. Lacy, Hebden Bridge.

Dorkings.—1, J. White, Warlaby. 2, J. Stott, Healey, Rochdale. *Chickens.*—1, J. Robinson, Garstang. 2, J. White, Warlaby. *hc*, H. Yardley, Birmingham; J. Stott, Healey. *c*, C. Chaloner, Whitwell, near Chesterfield.

Spanish (Black).—1 and Cup, N. Cook, Chowbent. 2, H. Beldon, Goitstock, Bingley. *hc*, H. Beldon; Birch & Boulter, Sheffield. *c*, F. & C. Haworth, Newfield, Haslingden. *Chickens.*—1, F. & C. Haworth, Haslingden. 2, W. & F. Pickard, Thorner, near Leeds. *hc*, T. & E. Comber, Warrington; Birch & Boulter, Sheffield.

Game.—1, C. W. Brierley. 2, H. M. Julian. *Chickens.*—1, J. Carlisle, Earby, near Skipton (Brown Red). 2, C. Chaloner. *hc*, E. Mann, Stand.

Game Cock.—1 and Cup, C. W. Brierley. 2, C. Chaloner. *hc*, W. Lomax, Stonecliough; H. M. Julian, Hull.

Game Cock (Within six miles of Haslingden).—1, N. Storey, Haslingden. 2, F. & C. Haworth, Newfield. *hc*, A. Sutherland.

Hamburghs (Golden-pencilled).—1, S. Smith, Northowram, Halifax. 2, H. Pickles, Earby, near Skipton. *c*, H. Beldon. *Chickens.*—1, W. Parr, Patricroft. 2, S. Smith. *hc*, T. Wrigley, jun., Tonge Hall, near Middleton; W. J. Harker, Allerton, near Bradford.

Hamburghs (Silver-pencilled).—1 and *hc*, H. Beldon. 2, Duke of Sutherland, Trentham. *Chickens.*—1, J. Walker, Knaresborough. 2, H. Beldon. *hc*, H. Pickles.

Hamburghs (Golden-spangled).—1, Duke of Sutherland. 2, H. Pickles,

hc, S. & R. Ashton; N. Marlor, Denton. *Chickens.*—1, T. Walker, jun., Denton, near Manchester. 2 and *hc*, E. Brierly, Heywood. *c*, J. Walker, Knaresborough.

HAMBURGHS (Silver-spangled).—1, Cup, and *hc*, H. Beldon, 2, W. A. Taylor. *c*, J. Fielding, Newchurch; H. Pickles, Earby. *Chickens.*—1, J. Fielding. 2, Ashton & Booth, Mottram. *hc*, H. Beldon, Bingley.

HAMBURGHS (Black).—1, C. Sidgwick. 2, D. Lord, Stacksteads. *hc*, Mason & Walker, Denton. *Chickens.*—1, A. E. Hanson, Castleton. 2, N. Rigg, Rochdale.

ANY OTHER VARIETY.—1, H. Beldon (Polands). 2, W. Hawey, Sheffield (Crevo-Cœurs). *hc*, W. Gamon, Chester (Polands); W. Hawey (Polands).

SELLING CLASS (Any variety).—1, F. & C. Haworth, Haslingden. 2, C. W. Brierley. *hc*, F. Shaw, Plas Wilmot (Black Red Game). *c*, W. A. Taylor, Manchester.

GAME BANTAMS.—*Cock.*—1, J. R. Robinson, Sunderland. 2, J. Crosland, jun., Wakefield. *hc*, T. Barker, Hill End, near Burnley. *c*, W. F. Entwisle, Leeds; J. W. Morris, Rochdale; J. Barlow, Musbury.

GAME BANTAMS.—1, W. F. Entwisle. 2, C. W. Brierley. *c*, J. W. Morris.

BANTAMS (Any variety).—1, H. Beldon. 2, W. Harvey, Sheffield. *Chickens.*—1 and *hc*, W. F. Entwisle. 2, J. Crosland, jun (Brown Red). *c*, T. Barker (Black Red).

TURKEYS.—1, E. Leech, Rochdale.

GEESE.—1, T. Houlker, Blackburn (Grey). 2, E. Leech.

DUCKS (Aylesbury).—1 and 2, Mrs. M. Seamons. *hc*, E. Leech.

DUCKS (Rouen).—1, T. Houlker. 2, E. Leech.

DUCKS (Any other variety).—1 and 2, C. W. Brierley. *hc*, T. C. Harrison, Hull; J. Sichel, Tinperley (Carolina); S. & R. Ashton, Mottram; A. & J. Trickett, Waterfoot, near Manchester.

PIGEONS.

CARRIERS.—1, J. Hawley, Bingley. 2, E. Horner, Harewood, Leeds. *hc*, H. Yardley, Birmingham; J. Chadwick, Bolton.

TUMBLERS.—1, J. Fielding, jun. 2 and *hc*, J. Hawley.

BARBS.—1 and 2, Capt. Heaton, Eccles. *hc*, E. Horner; J. Fielding, jun. *c*, J. Hawley.

OWLS.—1 and 2, J. Fielding, jun. *hc*, J. Hawley.

CROPPERS.—1, W. Harvey, Sheffield. 2, E. Horner. *hc*, W. Gamon; E. Horner.

FANTAILS.—1, 2, and Cup for best pen of any breed, J. Hawley. *hc*, E. Horner; J. Chadwick. *c*, H. Yardley; H. M. Maynard, Holmewood.

TURBITS.—1, E. Horner. 2, H. Yardley. *hc*, E. Horner; J. Fielding.

DRAGOONS.—1, J. Hawley. 2, W. Moore, Burnley (Blue). *hc*, T. Charnley, Blackburn (Blue). *c*, J. Lord, Rochdale; W. Harvey, Sheffield.

TRUMPETERS.—1, E. Horner. 2, W. Gamon, Chester, *hc*, J. Hawley; E. Horner. *c*, J. Hawley.

JACOBINS.—1, E. Horner. 2, J. Hawley. *hc*, T. Newell, Ashton-under-Lyne.

ANTWERPS.—1, J. Crosland, jun. 2, J. Hawley.

ANY OTHER VARIETY.—1, T. Newell (German Fairies). 2, W. Harvey, Sheffield. *hc*, H. Yardley; E. Horner. *c*, H. Yardley.

ANY OTHER VARIETY (Within three miles of Haslingden).—1, J. Holt, Haslingden (Black Carriers). 2, J. Hamilton, Haslingden (Black Barbs). *hc*, J. Hamilton (Blue English Owls); W. Kemp, Haslingden (Blue Owls). *c*, W. H. Ashworth, Tanpits, Helmshore (Blue Carriers).

RABBITS.—1, A. Crossley, Broomfield, Halifax (Lop-eared). 2, A. H. Easten, West Parade House, Hull (Himalayan). *hc*, J. Boyle, jun., Victoria Street, Blackburn (Lop-eared).

Messrs. Hewitt and Teebay were the Judges of the poultry; and Mr. Beldon awarded the prizes for Pigeons and Rabbits.

CLECKHEATON POULTRY SHOW.

THE first Poultry Show in connection with the Cleckheaton Agricultural Exhibition was held on the 24th ult. A large number of visitors attended, and for a first attempt it was a great success. All the arrangements were very good.

In Black and Brown Red *Game* there were twelve entries, and most of them included excellent birds. A cup was awarded to the best pen of Game—a very good pen of Black Reds. The second and third prizes went to Brown Reds, also good birds. The Duckwing Game were, as a class, very good. *Dorkings* were only of medium quality, being very much out of condition. The same may be said of the *Cochins*. The *Spanish* were good, but only four pens competed. In *Brahmas* there were seven pens, Mr. Leach, of Rochdale, being first with a good pen. The *Hamburghs* were not so good as we expected to see, being in the centre of the Hamburgh district.

Many of the *Ducks* and *Geese* were good and large in size.

The *Pigeons*, as a whole, were a nice show, there being many first-class birds amongst them.

GAME (Black Red or Brown Red).—1, W. Fell, Adwalton. 2, E. Aykroyd, Bradford. 3, H. Hatton, Cleckheaton. *hc*, G. Noble, Staincliffe; H. Jennings, Allerton, Bradford. *c*, W. Bentley, Scholes.

GAME (Any age or variety).—1, H. Jowett, Idle, Leeds. 2, W. Fell. *hc*, H. Jennings; H. Jowett. *c*, G. Noble.

DORKINGS.—1, 2, and *hc*, W. H. King, Rochdale. *c*, J. T. Beaumont, Huddersfield; Rev. G. Hustler, York.

COCHIN-CHINA (Any variety).—1, H. W. Illingworth, Idle. 2, W. & F. Pickard, Thorner. *hc* and *c*, J. W. Wilkinson, Bradford.

SPANISH (Black).—1, J. Gornall, Little Horton. 2, E. Brown, Sheffield. *hc*, W. & F. Pickard.

BRAHMA POOTRA.—1, E. Leech, Rochdale. 2, M. Scott, Idle. *hc*, L. Woodhouse, Bradford.

HAMBURGHS (Golden-pencilled).—1, S. Smitt, Northowram. 2, W. Clayton, Morton Banks, Keighley.

HAMBURGHS (Golden-spangled).—1, J. Rollieson, Lindley, Otley. 2, J. Murgatroyd, Idle. *c*, S. & W. Clapham, Keighley; S. Smitt, Northowram.

PHEASANTS (Black).—1, H. W. Illingworth. 2, E. Baxter, Idle.

FRENCH (Any variety).—2, R. Naylor, Rawfolds, Cleckheaton.

GAME BANTAMS (Black or Red).—1, Extra 1, and 2, G. Noble. *hc*, E. Brown, Sheffield; S. Schofield, Heckmondwike; C. Clegg, Staincliffe.

GAME BANTAMS (Any variety).—1, W. Greaves, Bradford. 2, A. Wood.

BANTAMS (Any variety except Game).—1, W. Brotherton, Idle. 2, S. and W. Clapham, Keighley. *hc*, W. H. Robinson, Keighley.

TURKEYS.—1, E. Leach. 2, Mrs. Spence, Weston, Otley.

GEESE (Any variety).—1, E. Leech. 2, J. White, Whitley, Wakefield. 3, W. H. King, Rochdale.

DUCKS (Aylesbury).—1, E. Leech.

DUCKS (Rouen).—1, E. Leech. 2, J. Crossland, Huddersfield.

DUCKS (Any other variety).—1 and Extra, W. Greaves, Bradford.

RABBITS.—*Lop-eared.*—1, T. Mitchell, Bradford. 2, W. Clark, Gomersal. *Any other Variety.*—Prize, Mrs. Spence, Weston, Otley (White Russian).

PIGEONS.

TUMBLERS.—1, H. Yardley, Birmingham. 2, J. Hawley, Bingley.

CARRIERS.—1 and Extra, J. Hawley. 2, H. Yardley.

BARBS.—1, J. Hawley. 2, H. W. Illingworth.

OWLS.—1, J. Hawley. 2, T. Eggleston, Halifax.

POUTERS OR CROPPERS.—1, J. Crossland, Huddersfield.

FANTAILS.—1 and Extra, J. Hawley. 2, J. Crossland.

DRAGOONS.—1, J. Hawley. 2, H. Yardley.

TRUMPETERS.—1, J. Hawley. 2, J. Crossland.

JACOBINS.—1 and Extra, J. Hawley. 2, J. Crossland. *hc*, T. Eggleston.

NUNS.—1, J. Crossland. 2, W. Lund, Shipley, Bradford.

ANTWERPS.—1, W. Lund. 2, S. Schofield, Heckmondwike.

ANY OTHER VARIETY NOT BEFORE MENTIONED.—1, H. Yardley. 2, J. Hawley.

Mr. James Dixon, Bradford; and Mr. Thompson, Southowram, acted as Judges.

BRIDLINGTON POULTRY SHOW.

(From a Correspondent.)

THIS annual Exhibition, in connection with the Agricultural Association, took place at Bridlington, on July 28th. Several pens of first-class birds were exhibited.

COCHIN-CHINA.—1 and 2, Miss Creyke, Marton Hall. *Cock.*—1, G. Holmes, Driffield. 2, Miss Creyke.

DORKINGS.—1, G. Holmes. 2, D. White, Driffield. *Cock.*—1, O. A. Young, Driffield. 2, D. White.

SPANISH.—1 and 2, G. Holmes. *Cock.*—1, J. Stabler, Driffield. 2, G. Holmes.

GAME.—1, J. Laycup, Driffield. 2, J. Woodhouse, Flamborough. *Cock.*—1, W. Watson, Snainton. 2, J. Laycup.

POLANDS.—1, Mrs. Procter, Hull. 2, G. A. Young.

HAMBURGHS (Golden-spangled).—1 and 2, G. Holmes.

HAMBURGHS (Silver-spangled).—1 and 2, G. Holmes.

HAMBURGHS (Golden-pencilled).—1 and 2, G. Holmes.

HAMBURGHS (Silver-pencilled).—1, G. Holmes. 2, Miss Creyke.

BANTAMS (Any variety).—1, G. Holmes. 2, Miss Creyke. *Cock.*—1, J. Duggleby, Driffield. 2, Master C. Richardson, Bridlington.

DISTINCT VARIETY.—*Chickens.*—1, D. White. 2, G. Holmes.

GEESE.—1, J. Nesfield, Buckton. 2, G. A. Young.

GEESE.—1 and 2, J. Nesfield, Buckton.

TURKEYS.—1, Miss J. Edwards, Ganton. *Poults.*—1, Miss J. Edwards. 2, Mrs. Chapman, Springdale.

DUCKS (Aylesbury).—1, O. A. Young. 2, J. Smith, Marton Lodge. *Ducklings.*—1, O. A. Young. 2, J. Smith.

DUCKS (Any variety).—1, G. Holmes. 2, O. A. Young. *Ducklings.*—1 and 2, R. Moody, Bridlington.

GUINEA FOWLS.—1, H. Merkin, Driffield.

PIGEONS.—*Croppers.*—1, W. Dobson, Bridlington. *Fantails.*—1, Miss Creyke. 2, T. Stabler, Driffield. *Carriers.*—1, W. Brand, Driffield. *Jacobins.*—1, R. Flemming, Springbank, Hull. *Any New or Distinct Variety.*—1, J. Duggleby. 2, O. A. Young.

RABBITS.—*Any Breed.*—1, W. Donkin. *Fancy.*—1, W. Donkin.

JUDGE.—J. O. Jolly, Esq., Green Hammerton, York.

BUDE HAVEN POULTRY SHOW.

THE following are the awards made at this Show, held July 30th:—

DORKINGS (Coloured).—1 and 2, Mrs. Thynne. *Cock.*—1, Mrs. Thynne. 2, A. Trewin. *Chickens.*—1, Mrs. Thynne.

DORKINGS (White).—1, T. Pickard.

SPANISH.—1, J. M. Braund. 2, W. E. Wackley. 3, R. Hoskin. *Chickens.*—1, W. Leach. 2, S. T. Pickard.

MINORCAS.—1 and 2, F. Gloyne.

GAME.—1, S. T. Pickard. 2, R. Francis. 3, W. H. B. Coham. *Chickens.*—1 and 2, N. Treleven.

COCHIN-CHINA.—1 and 2, W. L. Trewin.

BRAHMAS.—1, Rev. W. James. 2, Mrs. Thynne.

MALAYS.—1 and 2, H. Darch.

CORNISH.—1, H. Francis. 2, Mrs. Thynne.

HAMBURGHS (Golden-pencilled).—1, F. Barrett. 2, J. F. Delmar.

HAMBURGHS (Golden-spangled).—1, J. F. Delmar. 2, J. Woodley.

HAMBURGHS (Silver-pencilled).—1, J. Walter. 2, J. Penwarden.

HAMBURGHS (Silver-spangled).—1 and 2, W. M. Lancester. *Chickens.*—1, W. M. Lancester. 2, J. Banbury.

POLANDS (Golden-spangled).—1 and 2, H. P. B. Sly.

POLANDS (Black, White Topknots).—1 and 2, W. L. Trewin.

BARNDOOR.—1, D. Barrable. 2, J. Heal. 3, W. Sleeman. 4, H. Francis. 5, W. J. Lyle.

EXTRA.—1, F. Barrett. 2, Rev. W. Jones.

ANY BREED EXCEPT DORKINGS.—*Cock.*—1, W. L. Trewin. 2, H. Darch. 3, W. Bromell.

BANTAMS (Gold-laced).—1, R. Harris. 2, Withheld.

BANTAMS (Black).—1, J. Heal. 2, P. Heal.

BANTAMS (White).—1, H. Francis. 2, L. Fry.

GUINEA FOWLS.—1, W. M. Lancester. 2, W. H. B. Coham.

DUCKS (Aylesbury).—1 and 2, J. Heard. 3, W. Bines. *Ducklings.*—1, R. Hoskin. 2, J. Bines.

DUCKS (Common).—1, T. Pickard. 2, J. Heal. 3, — Cotton. 4, Miss Burton. *Ducklings.*—1, Miss Knight. 2, J. Medland. 3, Miss Burton.

DUCKS (Rouen).—1, Miss Wright. *Ducklings.*—1, W. Barrable. 2, E. Hockin.

GEESE.—1, 2, and 3, J. Heal.

TURKEYS.—1, J. Galsworthy. 2, G. Risdon. 3, Miss Burton.

PIGEONS.—1, D. Francis. 2, T. Modland. 3, D. Francis. *Barbs.*—Prize, J. M. Braund. *Pouters.*—Prize, J. M. Braund. *Fantails.*—Prize, Miss Radcliffe. *Jacobins.*—Prize, J. M. Braund. *Trumpeters.*—Prize, J. M. Braund. *Turbits.*—Prize, J. M. Braund.

RABBITS.—*Long-eared.*—1. Master H. Sanders. 2, Master J. Pickard. *Common.*—1, H. Pickard. 2, M. Olde.

JUDGES.—Mr. H. Leeworthy, Barnstaple, and Mr. Oatway, Bideford

LINCOLN POULTRY SHOW.

THE first Exhibition of the Lincolnshire Agricultural Society took place on the 29th, 30th, and 31st ult.; and though the entries of Poultry and Pigeons did not much exceed a hundred, some good birds were shown. The following is the prize list:—

DORKINGS (Any colour).—1, J. Hornsby, Grantham. 2, T. Marris, Ulceby. 3, W. Hutton, Gainsborough.

GAME (Any variety).—1 and Cup, B. Jarvis, Mansfield. 2, Rev. T. O'Grady, Ashbourne, Derbyshire. 3, E. Hubbard, Nether Langwith, Mansfield. *hc*, F. Watson, Kelvedon, Essex.

SPANISH.—1, T. C. & E. Newbitt, Epworth. 2, T. Marris. 3, G. Jackson, Newark.

BRAHMAS (Any colour).—1 and 2, C. Layland, Warrington.

COCHINS (Any variety).—1, J. N. Beasley, Pitsford Hall, Northampton (Buff). 2, J. Elgar, Osmanthorpe Hall, Newark (Buff). 3, C. Layland.

HAMBURGHS (Any variety).—1, J. F. Loversidge, Newark (Golden-spangled). 2, W. Ghest, Barlings, Lincoln (Silver-pencilled.

BANTAMS (Any variety).—1, J. W. Dudding, Howell, Sleaford. 2, T. Marris.

BANTAMS (Any other variety).—1, W. H. Tomlinson, Newark (Black). 2, J. Elgar (Black).

POLANDS.—1, T. C. & E. Newbitt.

FRENCH.—1 and 2, W. O. Quibell, Newark. 3, Col. Stuart Wortley.

ANY VARIETY.—*Cock.*—1, B. Jarvis. 2, W. O. Quibell (Brahma, Dark). 3, E. Hubbard.

GEESE (Any colour).—1, J. Elgar. 2, F. W. Brook, Branncewell, Sleaford. 3, F. Dawson, Sixhills, Market Rasen.

DUCKS (Aylesbury).—1, J. Hornsby, Grantham. 2 and 3, T. Fox, Lincoln.

DUCKS (Rouen).—1, W. H. Robson, North Reston, Louth. 2 and 3, J. W. Dudding.

DUCKS (Any other variety).—1, J. W. Dudding. 2, Hon. A. L. Melville, Brannston Hall, Lincoln (Decoy). 3, H. Freshney, jun., Grimoldby, Louth.

TURKEYS (Any variety).—1, J. N. Beasley. 2, J. B. Hides, Wisbeach Fen.

SELLING CLASS.—1, T. C. & E. Newbitt. 2, J. Hornsby (Aylesbury). 3, B. Jarvis (Game). *hc*, J. Hornsby; E. Hubbard. *c*, S. Spencer, Housham, Brigg.

PIGEONS.—1, W. Massey, Spalding (Carriers). 2, T. C. & E. Newbitt. *hc*, H. Snushall, Fleet Hargate, Wisbeach (Black Carriers, Turbits, and Hyacinths). *Extra.*—Extra, S. Sawyer, Lincoln (White Indian Fantails)

The Judges of Poultry and Pigeons were Mr. Thomas Chaloner, and Mr. W. B. Tegetmeier.

FULFORD POULTRY SHOW.

THE eighth Exhibition of this Society was held at Fulford, near York, on the 29th of July. The Show of this year has been better than any former show at Fulford, and the *Spanish*, *Dorkings*, *Game*, and *Hamburghs* would have been creditable to any show.

SPANISH.—1, W. Bearpark, Ainderby Steeple. 2, J. Cook, Bishop Wilton.

DORKINGS.—1, W. Bearpark. 2, Rev. G. Hustler, Stillingfleet.

COCHIN-CHINA.—1 and 2, Sheriff of York.

GAME (Any variety).—1, W. Bearpark. 2, J. Mollett, York. *hc*, G. Carter, Sand Hill, Bedale.

HAMBURGH (Spangled or Pencilled).—1, W. Bearpark. 2, Miss Sutton, Fulford.

HAMBURGHS (Silver-spangled or Pencilled).—1, W. Bearpark. 2, Sheriff of York.

ANY OTHER VARIETY.—1, C. Walker, Boroughbridge. 2, Miss Ward, Acomb Grange.

THREE CHICKENS (Any breed).—1, R. Swann, Acomb. 2, W. Bearpark.

BANTAMS (Any variety).—1, — Wheatley, Ilworth. 2, G. Hutchinson, Prospect House.

SELLING CLASS (Any variety).—1, G. Carter. 2, C. Triffitt, Cattal.

GEESE.—1, Rev. G. Hustler. 2, — Harrison, Acaster.

TURKEYS.—1, A. S Perfert, Fulford. 2, Rev. G. Hustler.

DUCKS (Any variety).—1, Rev. G. Hustler. 2, A. S. Perfert.

The Judge was Mr. A. Cattley, York.

EDINBURGH POULTRY SHOW.

The following awards were made at the Show of the Highland and Agricultural Society held at Edinburgh on the 28th, 29th, and 30th of July:—

DORKINGS (Siver-Grey).—1, D. Annan. 2, G. Lyon. *hc*, Sir J. D. Wauchope. *Chickens.*—1, Lady Montgomery. 2, A. Campbell. *hc*, A. Carswell.

DORKINGS (Coloured).—1, J. Allan. 2, J. Logan. *Chickens.*—1, Sir. G. Grant. 2, J. Clark. *hc*, T. Raines.

DORKINGS (White).—1, J. Logan.

COCHINS (Coloured).—1, G. Murray. 2, A. Campbell. *hc*, R. E. Brown. *Chickens.*—1, R. E Brown. 2, A. Campbell.

COCHINS (White).—1, W. Gibb. 2, G. Murray. *Chickens.*—1 and 2, Mrs. Ford.

BRAHMAS (Dark).—1, R. Brownlie. 2, T. Raines. *Chickens.*—1 and *hc*, J. Stuart. 2, J. A. Dempster.

BRAHMAS (Light).—*Chickens.*—1, J. A. Dempster.

SPANISH.—1 and 2, R. Somerville. *hc*, Mrs. Gracie. *Chickens.*—1, Mrs. Gracie. 2, R. Somerville. *hc*, Mrs. Dart.

SCOTCH GREY.—1 and 2, J. Meiklem. *hc*, R. Blair. *Chickens.*—1, J. Meiklem. 2, J. Logan.

HAMBURGHS (Gold-pencilled).—1, H. W. Pople. 2, W. R. Park. *hc*, J. Logan. *Chickens.*—1, W. R. Park. 2, J. M. Harvey. *hc*, J. Logan.

HAMBURGHS (Silver-pencilled).—1, J. Logan. 2, A. Crosbie. *Chickens.* 1, J. Logan.

HAMBURGHS (Golden-spangled).—1, J. F. Loversidge. 2, J. C. Miller. *hc*, Mrs. Brown. *Chickens.*—1, J. H. Macnab. 2, Mrs. Brown.

HAMBURGHS (Silver-spangled).—1, J. Logan. 2, J. H. Macnab. *Chickens.* 1, J. Logan. 2, J. H. Macnab

POLISH (Black).—1, J. Logan. 2, R. Smith.

POLISH (Silver-spangled).—1, J. Logan.

GAME (Black or Brown Reds).—1, J. Logan. 2, J. Waddell. *c*, D. Hardie. *Chickens.*—1, H. Goodall. 2, W. Sprout. *hc*, J. H. Macnab.

GAME (Duckwings).—1, J. Waddell. 2, J. Logan. *Chickens.*—1, H. Goodall; 2, J. H. Macnab.

GAME (Any other variety).—1, D. Harley.

GAME BANTAMS.—1, J. Gow. 2, H. W. Pople. *hc*, J. Waddell. *Chickens.* —1, Sir G. M. Grant. 2, J. Gow. *hc*, H. Goodall.

BANTAMS (Gold-laced).—1, W. Gibb.

BANTAMS (Silver-laced).—1, R. Frew.

BANTAMS (Any other variety).—1, 1, S. S. Mossop (Black). 2, S. H. Stott (Japanese). *hc*, J. Archibald. *Chickens.*—1, H. Goodall. 2, D. Forrester (White).

ANY OTHER VARIETY.—1, W. R. Park (Crêve-Cœur). 2, J. Logan (Black Hamburghs and Crêve-Cœurs). *Chickens.*—1, J. Logan (Black Hamburghs).

DUCKS (Aylesbury).—1, Mrs. Hendrie. 2, G. F. Lyon. *Ducklings.*—1, Lady Montgomery. 2, Mrs. Hendrie. *hc*, T. L. Livingstone.

DUCKS (Rouen).—1, D. Hardie. 2, J. Sharp. *hc*, J. Logan. *Ducklings.* —1, J Sharp. 2, J. Thomson. *hc*, J. Gibson.

DUCKS (Any other Distinct Breed).—1 and 2, J. Logan (Grey and White). *hc*, J. Thomson. *Ducklings.*—1 and 2, J. Logan (Black).

TURKEYS (Norfolk).—1, J. Gibson.

TURKEYS (Any other breed).—1, J. Stenhouse (Cambridge). *Poults.*—1, J. Stenhouse (Cambridge).

GEESE (Grey).—1, D. Hardie. 2, S. H. Stott. *hc*, J. Logan. *Goslings.* —1, D. Hardie. 2, S. H. Stott.

GEESE (White).—1, Duke of Buccleuch. *Goslings.*—1, Duke of Buccleuch.

JUDGES.—Mr. R. Teebay, Mr. Gelmore, Lord Binning, and Mr. H. Beldon.

THE INTRODUCTION AND PROPAGATION OF LIGURIANS.

(*Continued from page* 72.)

PRESUMING that the inteuding propagator of the Italian race has by the mode which I have already described, been enabled to establish one or more stocks of common bees in moveable-comb hives, I shall aseume that he has ordered some Italiau queens which he is anxious to substitute for the reigning monarchs. Let me then lay it down as an axiom, that *young bees receive an alien queen much more readily than old ones*, and that, therefore, the illustrious stranger runs comparatively little risk if she can be introduced to a population consisting entirely of juveniles. Supposing, therefore, that it is summer time when advice is received of the approaching advent of the Ligurian queens, a similar number of artificial swarms should be formed by removal in the following manner:—

During the middle of a fine day, when the bees are in full work, look over the combs until the queen is discovered upon one of them*, which place in the centre of an empty hive, and, if possible, support it on either side by a spare worker-comb. Then bring the combs of the old hive together so as to leave the vacancy on one side, closo it, and put it in a new position a short distance off, placing the new hive with the queen on the old stance. Every bee which has once taken wing will in the conrse of a day or two return to the old place, and thus make up a swarm, which, having a fertile queen and a comb full of brood, will probably do exceedingly well, whilst the old hive remains in the exclusive possession of the rising generation. On the eighth or ninth day (or sooner, if the Italians come to hand), the latter should be carefully examined by lifting the combs out one after the other, shaking off at the same time most of the bees so as to make sure that no royal cell escapes notice, and then carefully excise every one of them. If the arrival of the Italians be still longer delayed, this operation must be repeated a few days afterwards, so as to make sure of the extinction of the recent dynasty. When the alien queen arrives she must be first introduced to her future subjects under the protection of a queen-cage, in which she should be confined with two or three of her own workers until the next day, when she may be liberated, and when it is tolerably certain she will be well received. With regard to queen-cages, I may add that I always use an ordinary wire pipe-cover pressed into the surface of a brood-comb until its edges come in contact with the "partition wall," in the manner recommended by Kleine.

* Examine this comb carefully, and see that there are no royal cells upon it. If any are discovered, they should be at once excised.

On the 13th of July, and after the foregoing part of my article was written, I was unpleasantly reminded that there was yet another contingency which had not previously occurred to me. Being then with my family by the seaside, I was telegraphed for, and on my arrival in Exeter, found that a consignment of Italian queens had come to hand without any previous notice whatever. The remainder of the day being taken up with examining the condition of the royal travellers, and despatching most of them to different parts of the kingdom, I was obliged to defer operations on my own behalf until the next morning, when not having any colonies in a fit state to form artificial swarms, I was compelled to attempt the direct substitution of one queen for another, which was effected in the following manner:—

Looking over the combs I discovered and captured the queen, which with a few of her workers, I confined in a small box with a bit of sealed honeycomb, until the fate of the pretender should have been determined. Two days afterwards, I examined the hive, and slitting open every royal cell picked out its diminutive occupant with the point of a penknife. I then caged the Italian queen on a brood-comb, and next morning had the satisfaction of finding that no more queen-cells had been founded, and that, as far as could be judged by the demeanour of the bees, they were likely to accord a favourable reception to their new sovereign. I lost no time in putting their amicable disposition to the test by releasing the captive queen, and had the pleasure of finding that she was accepted without demur. It is not a little singular, that most of those to whom I sent queens in this unexpected manner, seem to have had but little difficulty in introducing them, and I hope ultimately to learn that all have been successful.

Imported Italian queens are, however, cheapest in the autumn (about October), when it is no longer practicable to form artificial swarms and thus to introduce them to juvenile bees only; but fortunately at this season the elders of the hive seem no longer to entertain an insuperable objection to a new sovereign, and the exchange may be effected with little or no risk, if only the requisite degree of caution be observed.

The hive must in this case be examined as soon as advice is received of the approach of the Italians, and the queen having been captured, should with two or three score of her subjects be placed with a bit of sealed honeycomb in a small, well-ventilated box, and carefully preserved as a *dernier ressort* in case of failure. Extinction of her dynasty having been afterwards effected in the manner before described, the Italian pretender to the vacant throne must in the same way be first introduced to her intended subjects, under the protection of a wire cage, which having been secured between two of the brood-combs, the hive should be closed and left undisturbed until the next day, when the cluster of bees surrounding the royal prisoner should be critically examined, and her liberation or continued incarceration determined on in accordance with their demeanour. If this cluster assumes the appearance of a dense knot of workers intertwined and clinging closely together with all the strength and energy of which they are capable, and momentarily increases its dimensions by the accession of numbers of bees which rush impetuously towards it from all parts of the adjacent combs, the regicidal frenzy continues in full force, and its hapless object must still remain within her prison-bars, in order to be protected from the fury of the raging multitude without. If, on the other hand, the bees which surround her cage are so few in number as to permit a glimpse of the movements of the royal prisoner and her companions in captivity, whilst none cling "like grim death" with curved and threatening abdomens against the wires of the cage, but rather assume the quiet and respectfully attentive demeanour which marks the ordinary deportment of workers in the presence of their acknowledged sovereign, the imprisoned queen may be at once released with every prospect of success, and if she be allowed to traverse the combs for a few seconds in view of the bee-keeper, he will be enabled to judge of the character of her reception. Should she obtain the respectful homage proper to the royal progress of a liege sovereign among her loyal subjects, the hive may at once be closed with every hope of a successful issue; but if she be seized and detained, she must again be restored to the protection of her prison, there to await the return of her rebellious subjects to a more dutiful frame of mind. There are, of course, almost infinite gradations and degrees of difference between the dense knot of would-be regicides which I have first described, and the comparatively few watchful attendants who wait with respectful patience to welcome their future sovereign on her release from captivity, and it requires some practice to enable the bee-keeper to determine with certainty when it is best to release an imprisoned queen, since, if she be left too long incarcerated, the outsiders seem at length to come to regard her with indifference, and she ultimately perishes either from lack of food or from the effects of her unnatural and constrained position.—A Devonshire Bee-keeper.

(To be continued.)

ENTHRONING LIGURIAN

I received two queens from Mr. Woodbury on the evening of the 14th July. The following morning I took the queens from two stocks which I had prevented from swarming, and made two swarms from the old bees, and then placed the two Italian queens on the top of the old stocks, putting perforated zinc between for them to fraternise through until the morning of the 16th, when I bored a small hole in the zinc, so as to allow one bee to pass through at a time; and when four or five had passed, finding that they joined the few workers in the box peaceably, I allowed a few more, until I had a good many mingled together. In about an hour I removed the perforated zinc and allowed them to ascend. They set up a joyful hum, and to-day (Saturday, July 17th), they are working cheerfully, and I believe I have not lost a single bee from fighting; so that I have been successful with both queens, having placed them at the head of two good stocks, with full combs and plenty of honey to keep them through next winter.—C. B. H.

OUR LETTER BOX.

Turkeys Roupy (*M. H.*).—Turkeys, like Pheasants, want much painstaking bestowed on them when young. They are very subject to the incipient roup from which yours are suffering. Keep the old hen shut up till the sun has dried the grass and the country, and there is no appearance of dew or frost. Choose a very dry place for the hen to be under the rip, and let it be tolerably open to the sun. Wash with cold water and vinegar the heads of those affected. Give them ale to drink, and administer to all two pills of camphor the size of peas. If you do this, shelter them from draughts, and let them out only when all is dry, they will recover.

Chickens Dying (*A Subscriber*).—Something disagrees with your chickens. They have too much of something, or they lack something. As we cannot tell which it is, we shall endeavour to give you some general rules, which, if followed, should prevent such a visitation. Keep the hen always confined; let her rip face the sun; see that the chickens are fed at daybreak; let them have dust to bask in; give them beer to drink; feed frequently on chopped egg, bread and milk, bruised wheat, meal slaked with milk, and cooked meat chopped fine. Let the rip in which the hen is confined be shifted to a fresh spot every day. If she is not on the grass, let her be supplied daily with a large sod of growing grass, cut with plenty of mould; she will tear it to pieces, and the chickens will find food and health from it. These are only necessary cares while the chickens are young or sickly, and it is because yours are suffering we advise it. You may give each a pill of camphor the size of a small pea.

Black Hamburghs' Plumage (*Black Hamburgh*).—We shall be very glad to give you our best advice. All the black breeds are prone to throw coloured feathers. Our best Spanish breeders can tell you the plague of white feathers in the hens and red in the cocks. You say the white feathers have appeared only in the cockerels. It is common. The Black Cochins were given up for this reason. The pullets were always black, the cocks never were. They were sometimes white, sometimes red. There is the same in Black Polands—the cocks very frequently throw red feathers. The Spanish chickens are all hatched black and white, and frequently keep white feathers till after the first year. If all the chickens come as you describe we should doubt the purity of the parents; if only the cocks are faulty we do not doubt it at all. The Black Hamburghs are a manufactured breed like the Black Cochins, and subject to the same vagaries. Tell us whether the parents are black, also whether the chicken pullets are black.

Paddock Poultry Show.—We have received complaints of letters to the Secretary having been returned to the writers, in consequence of insufficient address.

Feeding Cygnets (*M. C.*).—The proper way to feed cygnets is to give them bran, oats, and meal in a large flat vessel, the bottom of which should be covered with gravel or a sod of growing grass, the food placed on it, and the whole covered with water. Cygnets, and even grown-up Swans, love to make "little dirt pies."

Keeping Ducks (*Idem*).—Ducks as a rule do not require water. In the breeding season a tub or small pond about 4 feet square and 2 feet deep is necessary.

Gapes (*D. K.*).—Give each chicken daily a piece of camphor the size of a pea. Rail off the sewage gutter; let them have none but clean water to drink, and give them bread soaked in ale once daily.

General Treatment of Parrots (*E. Fell*).—Bread and milk should be the principal food, but not too much milk. Give also biscuits broken small, grain, nuts, and ripe fruit, also boiled Indian corn. Let them have water to drink, and sometimes a bath. Keep them very clean and warm.

Aged Parrot (*Trevor Dickens*).—We believe the paralysed bird is utterly incurable.

Bee-keeping (*T. P. F.*).—We know of no shorter or plainer pamphlet on the subject than "Bee-keeping for the Many." You can have it free by post if you enclose five postage stamps with your direction. It is often given away among cottagers.

From observations taken near London during the last forty-two years, the average day temperature of the week is 73.5°; and its night temperature 50.4°. The greatest heat was 92°, on the 18th, 1842; and the lowest cold 36°, on the 18th, 1866. The greatest fall of rain was 1.14 inch.

STRAWBERRY CULTURE—WATER SUPPLY.

THE stern ungenial weather of the past spring, and the very late time of the year at which real summer weather commenced, so retarded vegetation and injured the fruit crop as to make the present season a singularly marked one.

The past and present seasons would, if it were necessary, prove incontestably the advantages of high culture for the Strawberry, not only as regards the production of fine fruit, but also in enabling the plants themselves, by their robust constitution, to pass through such summers as that of last year with undiminished vigour. Wherever a full crop of Strawberries has been obtained this year, it is certain that proper means must have been diligently applied; for, after all, in the hands of a practical and energetic man, the production of Strawberries is simply a question of ways and means. In respect to success, there can be no fair comparison between A, who has heaps of rich manure, water in abundance at a convenient distance, above all, plenty of assistants to carry out his plans, and B, who is equal or even superior to A in skill and energy, but who, having but a scanty supply of those materials so necessary to success and so lavishly supplied to A, knows full well how futile and unavailing his efforts will be to produce any approach to a first-class crop. I would strongly urge upon all those who may be contemplating the formation or improvement of a garden, to keep in view an abundant supply of water. The soil, situation, and aspect are, it is true, important considerations, but however favourable they may be, if there is a deficient supply of water the crops must at times suffer. My own idea of a good water provision is one or more cisterns open at top, so that the water may be thoroughly soft and of the same temperature as that in which the crops are growing; and these cisterns should be sufficiently elevated to force the water through pipes and a connecting hose to any part of the garden. This method may appear at the first sight rather expensive, but if the saving of time and labour be taken into consideration it will be found to fully counterbalance, if not to exceed, the cost of an apparatus so thoroughly efficient.

Not very long ago I visited a garden in which the importance of this mode of distributing water appeared to be fully recognised; almost every glass house had its own elevated cistern with pipes attached conveying the water into the houses, in which, when necessary, other cisterns were placed. Watering at such a place must be a very different affair from what it is at others where the water has to be taken from a distance in water-pots.

I fear the Strawberry crop of the present season has, generally speaking, been poor. A friend, whose pleasant articles frequently appear in these pages, once observed to me that a really good gardener ought to be able in most instances to combat and to overcome the bad effects of an ungenial season. Although there is much truth in this remark, yet, as I have before observed, it is just a question of ways and means; for instance, where do we find a fair crop of Strawberries this summer? On those sturdy one or two-year-old plants whose unchecked vigour has been fully sustained by a plentiful application of rich stimulants; and it is amongst old plantations where the plants have become weakened in constitution by the combined effects of a parched soil, very little manure, and, in fact, a general starvation system that the principal failures have occurred.

The treatment of Strawberries during certain periods of their culture requires great promptitude and care: immediately after the crop of fruit is gathered the alleys should be cleared, and as much rich fat manure forked in as possible. Then, when the plants put forth their new roots into the rich food awaiting them, what is the result? Strong healthy foliage, plump well-developed crowns, in the hardier kinds an almost evergreen habit, and fine fruit in abundance in the following season. But if, after the crop is all gathered, the plantations are permitted to remain untouched for a month or more, and then, just as the fresh young roots are trying to force their way through the trampled and starved soil, the manure is forked in, the fork tearing up the young roots, and thus seriously checking the young growth at the very time it ought to be receiving every encouragement—in such a case failures are not to be wondered at; for by the time the plants have fully recovered from the effects of the ill treatment and are again fairly growing, the heat of summer is passing away, cold autumnal nights are setting in, the earth heat is dimiuishing fast, and consequently the thin weak tissue of the foliage succumbs to the inclemency of winter, and towards spring the plants become so denuded as to be hardly visible.

In forming new Strawberry beds, attention should be given to planting suitable kinds on various aspects, so as to obtain fruit early, also to have crops forming a succession to each other for as long a time as possible. Thus, for the earliest pickings such poor kinds as Black Prince and Keens' Seedling become really valuable when planted on a warm sheltered border facing the south or south-west. Princess Alice Maude, too, is a useful kind, following the others well, and is slightly earlier than Marguerite. With the ripe fruit of Marguerite the season for good Strawberries may be said to commence in earnest; for the first three, although very useful to the gardener for an early supply, would probably be esteemed worthless by those who care for nothing but large high-flavoured fruit. The general crop growing in any of the more exposed parts of the garden may be very usefully supplemented by a bed growing under the shade of standard fruit trees. For the last few days I have been supplying two dishes of Trollope's Victoria daily from a bed overshadowed by the branches of an old Pear tree, and I have thus been enabled to satisfactorily prolong the season of this favourite fruit.

In an article on this subject published last summer, I stated that a little rich soil stirred in with a trowel was all that was necessary to give the young plants or the runners a start, but last season caused an alteration in my plans in this respect. This year every young plant has had a small pot; the pots are filled with very rich cool soil, and are plunged to the rim, and in each pot one

offset still attached to the old plant by the runner is fixed and kept steady by means of a peg placed close to the outside of the pot. The plants are watered daily, and quickly become established; they are then separated from the old plants, and are at once turned out in the beds prepared for them. Plants so treated sustain no check, as each has its own compact ball of soil; and as care is taken to turn them into soil as rich as possible, and to give water when necessary, they make a rapid growth, and become stout thriving plants by autumn.

Of kinds that have produced fair crops this year, I may mention Sir Charles Napier, John Powell, Alice Maude, Newton Seedling—a hardy sort, very prolific, the fruit high-coloured and very firm, keeping better than that of most other varieties, but it is deficient in flavour and juiciness—Eliza, and, most vigorous of all, Trollope's Victoria. Duc de Malakoff has produced a fair crop, but the fruit did not attain its usual enormous size. Amongst newer varieties planted for the first time last season, I like the appearance of Lucas, President, and Cockscomb; especially that of the first two, which have proved very robust and prolific. Wonderful is not quite so free in its growth; its fruit, so far as I have seen, is in shape quite distinct from that of any other kind, but I have not yet seen enough of it to form a fair opinion of its merits.—Edward Luckhurst, *Egerton House Gardens, Kent.*

A FEW ROSE NOTES.

I believe jottings, however few, on this our favourite flower, are always acceptable, and I make no apology for adding a few to those I have already given.

Mdlle. Marguerite Dombrain.—It is always pleasant to have one's opinion confirmed by competent judges, and as, when Mademoiselle Marguerite Dombrain was brought out, I gave it a good character, I was very pleased the other day to receive a note from one whom all will acknowledge to be a really good judge, Mr. Rivers, commencing thus—"I have gathered to-day three blooms of Marguerite Dombrain, the most magnificent Roses I ever saw—it is La Reine spiritualised."

Maréchal Niel.—It is quite clear that this is a Tea-scented Noisette, and not a Tea Rose, and that like all of that class, it does best on the Briar. Then there is no question of its flowering, and no need of a wall, although it succeeds, perhaps, best there.

Marie Sisley.—This is one of the most lovely Tea Roses that we have received of late years, the colour of the petals is a very delicate primrose, with a deep border of rich pink. Even during the hot weather it has been lovely, and when the temperature becomes cooler I can well imagine that its beauty will be increased; in the meantime I would strongly advise all who grow Tea Roses to get it, and propagate it, for I venture my Rose reputation on its being a general favourite, and I congratulate my friend, M. Guillot fils, on having raised it. It is more rotund than Tea Roses generally are.

Adrienne Christophle.—Another very beautiful Tea Rose. The colouring is very rich; sometimes the centre is of a beautiful deep peach, at other times coppery yellow, while the outside petals are deep rich yellow. At present there is a slight degree of looseness about the flower, wanting the fine firm petal of Madame Margottin. This may improve, but under any circumstances the Rose is beautiful, and will, I am sure, be generally grown.

Souvenir de Monsieur Poiteau.—The second crop of bloom has shown some very large flowers; they still retain the peculiarity of colouring which marked the earlier ones. It has the defect of being somewhat rough in the centre; but withal it is a Rose that must be grown.

Madame Thérèse Levet.—A Rose that was missed when it came out, but is now in the class of deep pink flowers. A most prominent flower.

Charles Verdier.—I have this year been disappointed in this flower, so very few of the flowers have opened, showing, in fact, too much of the La Reine blood; but a friend who was visiting me the other day, says that with him it is very fine.

Baroness Rothschild.—No doubt one of the greatest acquisitions we have had of late. The flowers are large, of a lovely pink colour, and it is altogether a first-rate variety.

Monplaisir.—This is, doubtless, a Gloire de Dijon, having exactly the same habit, and foliage, and form of flower: the colour is different, much paler, more like what Gloire de Dijon is when exposed to the sun.

La France fully maintains the good opinion I had formed of it; it is especially good early in the season, and late in autumn; the buds are at all times most lovely.

Jean Cherpin.—I have been greatly pleased with this Rose this year. It is not full, I know, but there is a richness of shading about it that I cannot call to mind as equalled by any other Rose, and as I do not grow for exhibition, but for my own pleasure, and that of my neighbours, I can afford to have flowers which are not exactly show flowers, if they possess some one good quality.

Thyra Hammerick.—I have again to express a favourable opinion of this new Rose. It is quite in the Duchess of Sutherland style, but a great improvement on that old Rose.

Miss Ingram.—Never was there a greater disappointment than that occasioned by this new Rose. It was hailed by us all as a grand addition, believing as we did that it was a Hybrid Perpetual. It would then have been valuable; as a summer Rose it is useless, being a reproduction a *leetle* improved of the old Lady Stewart.

Margarita (Noisette).—A regular rambler, but as yet showing no sign of bloom; if it is going to partake in this respect of the qualities of Cloth of Gold, it will not do for us; but it is too early yet to judge.

Duke of Edinburgh.—A splendid high-coloured Rose, deep shaded crimson, good in habit and constitution, and sure to be in every winning stand.

I have here mixed together new and old, and have merely given such notes as struck me in looking over my Rose trees, thinking that such notices may be of assistance to others. My locality is a sheltered one, my soil is good, and my Roses are all on the Manetti stock.—D., *Deal.*

UNHEATED ORCHARD HOUSES.

The present unusually unfavourable season for fruit culture seems to have caused owners of unheated orchard houses a degree of discouragement which is hardly called for. In a former article on the subject I mentioned one cause of failure which I believe to be universal, and that is overcropping, with its concurrent evils of overcrowding, shading, or in any way obstructing the free access of sunlight and air to all parts of these structures. By any or all of these means the true use of unheated orchard houses is set aside. I shall here mention very briefly the principal causes of the short crops of this season—in my opinion, at least, for many different theories are afloat.

And first, in the case of trees in the open air. These could hardly have suffered, even in light soils, from the excessive heat of last summer. We can understand an increase of red spider and mildew, but not sufficiently severe to neutralise the good effects of the sun's rays in thoroughly ripening the shoots. At Montreuil, where there are few Peaches this year, the extremely light colour of the calcareous soil is easily remedied by layers of mulching and dark earth. The mild winter which we had was eminently suited to the Peach and other crops; but there can hardly be a doubt that the excessive and continuous downpour of rain, with the lowered temperature, completely and mechanically washed away the pollen, so that scarcely a bloom could set. Against this penetrating and prolonged drenching slight screens of tiffany must have been quite useless, and nets of woollen material no better. What we must eventually come to for the open wall, are screens of stout calico, of the same texture as a soldier's "shelter tent," or as the French say, *tente d'abri.* Such a tent, when placed at a greater angle than 45°, will throw off many hours of rain, but is not to be relied on at a less angle. Having myself made many such, and also used them for sketching, I can speak with certainty. This calico would also prevent the lodgement on the young leaves or blooms of fruit trees, of sleet or snow, which, melting under a sudden gleam of sun, are fatal to vegetation. Either rolled up, or with sliding rings, which I think Mr. Radclyffe, an excellent authority, now uses, these cheap calico screens would have saved much of the out-door fruit crops this year. Of course, they require attention to take advantage of casual sunshine and arrest radiation, and give to some extent the same trouble that orchard houses do.

In the case of orchard houses, it is evident that neither this downfall of rain, nor the low and damp temperature, can quite account for failure, as they can be guarded against in a great measure. I shall, therefore, dismiss these as sole causes of the evil, and endeavour to trace it elsewhere. The chief reasons of ill-success have been already asserted in this paper to be overcropping and overcrowding; and it is evident that an un-

heated orchard house, in which the trees have stood too thickly together for several seasons, can have but a poor chance in unfavourable springs for setting the blooms. The trees must gradually have become full of dwarfed shoots, and the foliage been a prey to insects, whereby the energies of the tree were diminished. It would be impossible to regulate the shoots in such a house, or to obtain a free circulation of air, or even to renew the dressing of the pots. When, therefore, the exhausting blooming process was at hand, there was no reserved vitality in the trees; they had acquired a feeble habit of growth, and had nothing for an emergency. If to such a state we add the presence of Peach trees trained up the rafters, or worse than this, of luxuriant young Vines obstructing the sun's precious rays, can we wonder at the crop either not setting or not stoning?

Where the demands of a large establishment require a supply of early salading, or young Peas and Beans, or early Potatoes in pots thickly placed between the fruit trees, and a row of promising Strawberry pots lines the front, not to speak of a large stock of valuable bedding plants of all sizes and kinds, all of which require abundant supplies of water at the very period when the evaporation from it is fatal to the bloom—where these and such exist, why need we accuse the climate of failing to set our fruit without fire heat? Again, it is a theory with some, that ventilation cannot be too free in orchard houses, and often we are glad to escape from these into the open air, on account of the deadly cold draughts. Many orchard houses are most injudiciously placed, and all low and ill-drained localities are prejudicial to the setting of bloom. For the same reason stagnant and damp air is fatal when enclosed within glass. Another, and to my mind an especial cause of failure in cold localities, or generally in such springs as the present, is the faulty construction of many orchard houses. On this large subject I will here only say that a few such experiences will show that lean-to houses with solid back walls are far more favourable for Peach culture than span-roofed houses. The latter, though handsomer, are unfit for the colder counties. They cool down more thoroughly than lean-to's, and lose far more of the earth heat during the winter. By means of extra thick walls, and judiciously husbanding winter gleams of sunshine, a good lean-to is a week or two in advance of a span-roof at all seasons, and can better carry the bloom through the period of risk, being warmer at night, and more equably warm at any time. The use of a stove would also be more economical in a lean-to. A short brick flue, not very expensive to make nor to use, would save any crop in a very large lean-to, and by a judicious selection of very early Peaches, the crop would be weeks in advance of that in an unheated span-roof. In the last, I may here say that late Peaches should not form any large proportion.

But not to dwell on this portion of the subject, I here wish to add, that I am still of opinion, in spite of that clever writer "Archambaud's" adverse criticism, that "trees can really be made to acquire a habit of production which shall render them independent of atmospheric changes"—that is, of course, when under the artificial condition of culture in glazed structures. I have this season a very fine crop, abundant, well-coloured, and of unusually good size. Some sorts which I was on the point of discarding are wonderfully resuscitated this season. Golden Purple has its old rich lake mottles and pink ground, while Canary has become a 9-inch-round Peach, dissolving, and rich, but its fault, alas! is that it is a shy bearer. I can fancy my good friend Rivers sitting in his arm chair, with his usual pipe, and laughing at my "clerical error," in stating Early Rivers to have been 8½ inches "in diameter," but in the next paragraph he says that I have "correctly described it."(!) It is, without doubt, the best very early Peach I have seen. The stones were quite perfect, and have been sown already.

Is it too much to consider that having my usual amount of crop in this year of general shortcoming, it may be due to the habit of the trees themselves? It is they, after all, which have done it, and it was because for so many years having been regularly thinned down to much below their powers of production, they had a reserve of vitality (favoured, no doubt, by last year's sun), which store of energy they have used up in a gracious effort to oblige their master. A plant will, year after year, be made to produce about the same number of flowers, provided in no one year any extraordinary demand shall be made on its strength. Should my trees be weaker next season, it will only be because this year the crop is unusually large.

Nevertheless, I have much faith in my tried cordons, which have never yet failed. Nor do I consider that potted trees or standards could compete at all with these at any time, and on occasions like this would have no chance. Potted trees have their exclusive merits, and so have standards, but the bulk of my crop has been, and shall all the more in future be taken from cordons in the borders. As to pyramidal trees planted out, the less we use them the better for profit. Diagonal cordons on the back walls, or parallel with the houses; spiral cordons in the borders intermixed with pyramids in pots; a row of potted trees near the glass, and some vertical cordons, single, double, or triple, for the sides and corners; the whole house kept free from bedding plants or such like; the roof perfectly clear; ample means judiciously used for ventilation; careful thinning of the crop; no overcrowding; adaptation of the form of the house to the site and climate—these form what are chiefly required in unheated orchard houses.

Next season, let us hope, will find our trees refreshed by rest from production; not, however, that such irregular cropping is advisable. By not expecting too much from unheated houses, we shall arrive at a fairer standard. I have had visitors who looked with evident disappointment at excellent results, as I thought. Almost the first idea of cultivators is to grow a little of everything, by doing so they shortly arrive at growing nothing at all.

The above remarks apply, of course, to beginners, of whom there are many; but there is no doubt whatever that orchard-house culture has made wonderful progress, and much sound knowledge is current among amateurs.—T. Bréhaut.

RUBUS ARCTICUS.

I observe in a recent number an inquiry by "G. S." as to whether any of your correspondents ever fruited this elegant but neglected plant, which he has seen thriving in the open air so far south as Warwickshire, and the fruit of which was stated by Linnæus to be delicious, and commonly preserved in Sweden. I grew a bed of this diminutive Raspberry for eight or ten years at an altitude of about 450 feet in Midlothian, on an easterly exposure where the sun never shone after 9 o'clock A.M. The soil I used was good sandy peat, such as would do well for growing Heaths in, and which was laid about a foot deep over a bed measuring 4 by 8 feet. The Rubus spread in it rapidly till the bed became densely filled, and yielded a profusion of its pretty red flowers in spring, which were succeeded in due course by about a third of their number of pretty bright red Raspberry-like fruit, of which I had no difficulty some mornings in gathering a handful, which were really delicious. I have noticed that it will not thrive, or at least fruit well, if shaded by overgrowing trees or shrubs. My bed was shaded from the midday sun, as before stated, by a wall, but was otherwise perfectly exposed; and I have often thought that the Arctic Raspberry would form an excellent and appropriate fruiting plant if cultivated in the gardens of Highland shooting lodges, where it would be an estimable rarity to sportsmen about the 12th of August, after leaving the Strawberry season in the south.

I may also mention that alongside of the Rubus I had a similar bed of that pretty namesake of the immortal Swede, Linnæa borealis, which in May or June was profusely covered with its tiny, drooping, delicately-scented, flesh-coloured flowers; and throughout the year its prostrate, creeping, leafy stems formed a beautiful verdant carpet, vastly superior to many of our modern fashionable bedding plants. Having on one occasion been favoured by a visit from a Swedish agriculturist, he became quite ecstatic on seeing it in full bloom, jumping and bawling out at the extreme pitch of his voice, "Linnæa! Linnæa! our Linnæa!"—W. G.

SUPERIOR BEDDING PELARGONIUM.

Among a rare collection of Scarlet Pelargoniums by far the most beautiful bedder I have this year is Bayard, raised by Mr. Pearson, of Chilwell. In a trying situation, and through two months of a trying season, whether in heat or cold, wind or rain, it has been in brilliant beauty, the trusses many and large, and the intense crimson unimpaired. My gardener finds it equally good for forcing, and, indeed, like its namesake of old, I think it *sans reproche*.—Sans peur.

Roses on their Own Roots.—I would fain remind those who wish to try Roses on their own roots, that now is the best

time to plant; they will make good growth, and form fresh roots, and almost a season will be gained; at any rate, a much finer display may be secured next season.—D., *Deal.*

PAPERS READ AT THE HORTICULTURAL CONGRESS AT MANCHESTER.

COVERING WALLS WITH GLASS FOR THE PROTECTION OF FRUIT TREES.

The uncertainty of securing good crops of our finer fruits, such as Peaches, Nectarines, and Apricots, owing to the injuries from spring frosts, makes some kind of protection almost a necessity in our climate.

Lately orchard houses have been prominently advocated by Mr. Rivers and others, and when properly managed they have been a source of interest and profit to amateurs and gardeners with limited means of growing fruit on walls or in hothouses. Where there are walls with a southern aspect in gardens, a covering of glass will, however, be found the cheapest and most certain way of securing crops of our finer fruits. Where Peaches, Nectarines, and Apricots are only required to ripen by the natural heat of the season the expense of heating such structures artificially need not be incurred. The spring frosts likely to occur in March and April will not injure the blossoms, for I have proved this here on an Apricot wall temporarily covered with glass lights. Last year on the 12th of April the temperature was 8° below freezing, yet the fruit trees in bloom, and young Apricots as large as filberts, were uninjured under the glass covering, but on the open walls the crop was quite destroyed even where protected by branches and nets. For the last seven years the crop has never failed on this wall until the spring of the present year, for some varieties of Apricots are only thinly set with fruit. The season, therefore, may be called an exceptional one, and the failure in the crop accounted for by the excessive warmth in February followed by a dull and cold March. The trees showed plenty of healthy blossoms, but the pollen seemed glued together and did not disperse, and even the fruit where set dropped off from the sudden cessation of the flow of sap. Some varieties of Apricots on this wall, however, have set a good crop, such as the Kaisha, Breda, and Musch-Musch. In the midland districts all unheated orchard houses have very thin crops this year, showing that artificial heating is requisite in such structures in springs like the past.

When the new kitchen garden was planned at Welbeck, a range of south wall nearly 800 feet long was covered with glass on a novel principle. All the framework is of iron, and the roof made on the ridge-and-furrow mode, and glazed with strong plate glass cast on purpose to suit the curve of the roof. The openings for top ventilation are made in the back wall, and every alternate light in front is opened and shut by machinery worked from the inside. The height at the back wall inside is 13 feet, in the front 7 feet 6 inches, and the inside width 7 feet 4 inches. The structure is heated by hot-water pipes, and they were found very useful this spring. Good crops of Peaches and Nectarines have been secured, as well as plenty of Cherries, Plums, and Pears grown in pots. Fire heat is only used in the blooming time or in the autumn to ripen the wood, as the object is to get a succession of Peaches and Nectarines after the hothouse ones are over. In such structures, if unheated, it is advisable not to exceed 5 or 6 feet of inside width, so that the heat stored up in the back wall may have sufficient power to expel any frost when the trees are in bloom. In March and April the sun heat in clear frosty weather is often very strong, and when the house is shut up early in the afternoon there is quite heat enough reflected from the back wall to keep the blossoms safe.

The long range of glass-covered wall here has a very light and imposing appearance from the absence of any timber in the construction, and from the ornamental iron bays placed every 22 feet in the inside. These bays are for growing hardy Grapes on, and some varieties have this spring shown plenty of bunches to festoon the tops of the bays. All the iron work in the interior is painted of a light sky-blue tint, and the effect is very pleasing. The walk inside is a stone pavement laid on brick-on-edge walls, so that the roots of the fruit trees may run between them.

Besides the advantage of furnishing a promenade in bad weather, this extremely long range is useful for so many purposes that I must detail them at length. In the front, where the two rows of 4-inch pipes are placed, there is an iron grating covering them. Its width, 2 feet, is sufficient for a long row of three hundred fruit trees in pots to stand on. In April and May bedding plants in immense quantities can be placed between the pots, in order to harden off for planting out in June.

The fruit trees grown in pots consist principally of Cherries and Plums, and a few of the best varieties of Pears and Apples. No Apricots are required here for pot culture, as a sufficient supply is obtained every year from a wall protected by glass lights. The Cherries grown in pots come in about two weeks before those grown on the walls, and consist of the following kinds according to their time of ripening—Belle d'Orleans, Early Purple Gean, Werder's Early Black, May Duke, Waterloo, Black Tartarian, Cleveden Bigarreau, and, for the latest, Florence and Late Duke. The following kinds of Plums are grown in pots in quantities—viz., Early Favourite and Mirabelle Brahy's Green Gage, Jefferson, Cox's Emperor, Kirke's, Oullin's Golden Gage, Magnum Bonum, and Golden Drop. The Pears and Apples grown in pots are confined to a few varieties esteemed for their earliness, fine flavour, or colour. Pears.—Citron des Carmes, Doyenné d'Été, Yat, Jargonelle double-grafted on the Quince, which bears freely; Williams's Bon Chrétien, Marie Louise, and Beurré d'Amanlis Panaché, a variety beautifully striped with red; Doyenné du Comice, and Beurre Clairgeau. Apples.—Cox's Pomona, beautifully coloured when grown in pots; Cox's Orange Pippin: Melon and Northern Spy, both American Apples; and a beautiful Russian sort named the Red Transparent.

The selection of Peaches and Nectarines planted against the back wall comprises some of the new kinds raised by Mr. Rivers and the best of the old varieties. The Peaches, according to their time of ripening, are—Early Beatrice, Early York, Early Alfred, Dr. Hogg, Early Mignonne, Grosse Mignonne, Noblesse, Malta, a delicious-flavoured and medium-sized Peach of the Noblesse section; Stump-the-World, Barrington, Late Admirable, Walburton Admirable, Gregory's Late, Téton de Venus, and Salway. The Nectarines, in the order of ripening, are—Fairchild's Early, a very old small red kind; Hunt's Tawny, Rivers's Pine Apple, Violette Hâtive, Elruge, Murrey, Downton, Rivers's Albert Victor, and Victoria.

Another great use of this glass-covered wall is for producing salads in the winter months, for without much trouble a succession of fine succulent Lettuces and Endive can be had every day when wanted. The Endive is lifted with balls of earth and put into covered boxes in the Mushroom house, where it becomes sufficiently blanched in three or four days. The Lettuces are planted in the border in the autumn, and a slight covering of hay preserves them from severe frosts should the hot-water pipes not be used. A good supply of blanched Chicory is likewise had by sowing it in July on a north border, and lifting it, when wanted, to plant in large covered pots, where it soon blanches, and forms the *barbe de capucin* of the French salads.—William Tillery, *Welbeck.*

ON THE RESULT OF A FEW EXPERIMENTS WITH SUBTROPICAL PLANTS AT BATTERSEA PARK

DURING THE WINTER OF 1868-69.

Although subtropical gardening has found a home up to the present time only in the affections of the few, and consequently any remarks upon the subject can have only a partial interest; yet horticulture having planted one of its earliest standards in Lancashire, and met with signal and the most flattering support in and around the great city of Manchester, it is felt that no apology need be offered for introducing the subject I have chosen on this occasion, feeling that whatever is connected with the advancement of horticulture will not be without interest.

That the season referred to was a remarkably mild one, preceded by one of the finest English summers on record, is a fact that will be fresh in the recollection of all present. It may, therefore, with some force be argued that the same results would not follow a severe and unpropitious winter as those which have called forth these remarks—which, however, is a point we may reserve for the present, to be answered by future experience—suffice it to say that the experiments carried out at Battersea last winter were based upon similar tests made on a smaller scale during the last five years; and as regards Cannas, Erythrinas, Aralia papyrifera, and other plants, it may be asserted that if a covering of dry litter, or other loose non-conducting material, such as leaf mould, cocoa fibre, &c., of sufficient thickness to exclude frost, be employed, the plants beneath the covering would not be injured by cold, no matter how severe the frost. We have a parallel case described in reference to a plant of a totally different habit from those before alluded to—namely, Musa Eusete, the great Abyssinian Banana. The stem and roots having been effectually protected from frost and wet by similar means, it was preserved in perfect health during the winter of 1866-7 in the open air in a garden near Paris, producing a most luxuriant growth, and being admired by all who saw it, in the following summer (1867): and it is probable that the stems of Eucalyptus, and similar tender trees, which readily produce vigorous shoots from the stem, may be preserved in the open air in this country by similar means.

A covering of dry litter is the most simple means we possess for the protection of plants, and in adopting it a principle is involved that may be made subservient to the tastes and requirements of cultivators of subtropical plants, by employing such non-conducting material to exclude frost from the plants to be protected, as may enable the cultivator to nurse up evergreen shrubs, and so mask and render ornamental the otherwise unsightly subtropical beds during winter.

By means of the covering of litter alluded to, a bed of Canna peruviana, edged with C. expansa, 80 feet by 8 feet, has been preserved for the last two winters from injury, the former having attained the height of 12 feet last year, and it is now growing luxuriantly, and 5 feet high. A bed 45 feet by 7 feet of Canna Annei, another of the same variety, 70 feet by 8 feet, the former bed having stood one winter, the latter two—in these the plants grew 12 feet high last year, and are now over 5 feet. Other beds of Canna, varying in size from 60 feet by 8 feet to 20 feet by 6 feet, have been preserved out of doors by the same means, and are now equally vigorous. They are planted

in part with the following varieties, all of which have been found to stand well under this treatment—viz.,

Canna zebrina	Canna rubra superbissima
zebrina coccinea	floribunda
picturata fastuosa	aurantiaca splendida
peruviana	Annei rosea
limbata, now 5 feet high, four winters out	indica rubra
	grandiflora floribunda
nepalensis	Warscewiczii
Sellowii	Madame Année
grandis	expansa

The kinds of Canna named below, having very fleshy succulent roots, have not stood so well; the beds, of which they formed part, have required to be made good to some extent, and they cannot, therefore, be relied on for out-door winter work—viz.,

Canna edulis	Canna metallica
discolor	gigantea
robusta	nervosa
nigricans	

Erythrina.—Two round beds, each 9 feet in diameter, and one oblong bed, 42 feet by 5 feet, have stood out last winter uninjured, including

Erythrina ornata	Erythrina profusa
Marie Bellanger	Madame Bellanger
laurifolia	ruberrima
crista-galli	Hendersonii

The continental hybrids of these showy Coral Trees were expected to prove very tender; all the varieties, however, are growing very luxuriantly, and abundance of flowers is looked for. Only one plant in the three beds has sustained any injury, and this through field mice eating the bark.

Aralia papyrifera, the Chinese Rice-paper plant, is very justly regarded by many as one of the very finest ornamental-foliaged plants used in subtropical gardening. This plant, in a bed 13 feet in diameter, attained 5 feet high from cuttings struck in the spring of 1868. The plants were left out last winter, and although killed to the ground, the thick fleshy roots have this season produced numerous strong shoots or suckers. These are produced irregularly, and require to be thinned out, so as only to retain a crop; and a few spaces have required filling up to render the bed complete.

Aralia Sieboldii.—This differs from the foregoing in habit and appearance, and is of equal merit as a fine-foliaged plant; indeed, it is more valuable from its proving quite hardy, which we may be justified in stating after five winters' trial.

Echeveria secunda glauca.—This Mexican succulent, useful for the margins of beds and other purposes, is more hardy than is generally supposed. Having heard last year from Mr. Rogers, gardener at Bury Hill, Taplow, that it had borne 22° of frost the previous winter with him, a margin of one of the circular beds at Battersea was left out last winter. The plants on the southern half of the bed were uninjured, while every plant on the northern side was killed.

Solanum laciniatum elegans.—This elegant-foliaged plant has borne the past winter, and is now producing its neat pale blue flowers. This species, together with S. betaceum and S. pyracanthum, bears the winters at Rose Hill, Exeter, and, although sometimes killed to the ground, seldom fails in shooting up from below. In the same garden at Rose Hill, Cannas are grown out of doors, and never taken up in winter, except for the purpose of thinning and re-arranging the roots.

I must now conclude these remarks with the enumeration of the following plants, which have held their place out of doors last winter, and although not of sufficient importance to demand each a separate notice, are, nevertheless, useful adjuncts in subtropical arrangements—viz., Gunnera manicata, Polymnia maculata, Polymnia canadensis, Hibiscus palustris.—J. Gibson, *Battersea Park*.

VARIOUS METHODS OF GRAFTING.

WITH AN ATTEMPT TO INQUIRE INTO THE INFLUENCE WHICH THE STOCK EXERCISES UPON THE SCION, AND *vice versâ*.

"You see, sweet maid, we marry
A gentler scion to the wildest stock,
And make conceive a bark of baser kind
By bud of nobler race: this is an art
Which does mend nature, change it rather; but
The art is nature."

By the above quotation from "The Winter's Tale," it would appear that Shakespeare (whose profound knowledge of human life in all its phases has been, and will long continue to be, the wonder and admiration of succeeding generations of mankind), was by no means ignorant of the art of grafting. It is even reasonable to suppose that he would hardly have written the above lines had he not practised this art himself, or, at least, been thoroughly conversant with, and fully aware of, the desired objects for which the operation is usually performed. This art would, indeed, appear to be of the greatest antiquity, and the date of its discovery, like the name of its earliest practitioner, is hidden in the mists of countless ages. The practice is alluded to in Holy Writ, and Pliny and other ancient writers have also referred to the subject. In some of their writings fabulous descriptions are given of extraordinary fruit trees so grafted as to produce sundry and very dissimilar kinds of fruit, such as Apples, Plums, Figs, Grapes, &c., upon the same tree; but it will readily be supposed that if any such trees ever existed, they must have been produced by similar means to that said to be sometimes resorted to on the Continent at the present day, where trees are occasionally produced and offered for sale, on which appear to be growing the Orange, the Myrtle, the Pomegranate, &c., all upon one stem. All this, however, as may be supposed, is merely a deception, accomplished by boring out the centre of the stem of the largest variety used, and drawing the smaller stems of the other sorts through the hollow tube thus formed, each individual plant retaining its roots, and in this state a struggling existence is supported for a time. By the adoption of similar means the Strawberry plant has been represented as growing from the stem of a Rose tree. This, too, is accomplished by taking the runner through the Rose stem, which had previously been hollowed out for the purpose, while the roots occupy the same soil as that in which the Rose tree is growing.

It may, I think, be reasonable to suppose it possible that nature or accident may have first suggested the practice of grafting, as instances are frequently to be met with in woods and thickets where branches of trees happen to cross and press upon each other; and the friction caused by the action of the wind in time displaces the bark, and as the branches increase in strength this friction is resisted and the pressure increased until the result is a permanent and organic union. This may be considered as grafting by approach, a practice which cultivators have imitated in the method known as inarching.

Various modes of grafting are practised, all of which under certain circumstances have their respective advantages, but of these methods the limits of this paper will only allow me to glance at those which are found to be the most applicable to general purposes; and many other so-called methods may be considered as merely modifications of them.

In all methods of grafting it is of the greatest importance that similar parts should be placed as much as possible in contact with each other, and on this account the method known as Saddle-grafting may be considered amongst the best, as presenting the largest possible surface to receive the ascending fluid or sap. This method, however, does not appear to be so generally practised as might be expected—possibly on account of time being required to perform the operation, and it is also necessary that the stock and scion should somewhat nearly correspond in size. In performing the operation the stock must be cut into the form of a sharp inverted wedge; the scion split up the middle, and its sides pared down until it exactly fits the stock. By this method the leading shoots of Conifers and other trees can be grafted with great facility, performing the operation while the wood is only partially ripened, and this will usually be found to be the case about the middle of August.

Whip-grafting is probably the commonest method of grafting, and that by which fruit trees, such as Apples, Pears, &c., are usually increased. The *modus operandi* is to head or cut down the stock to within 2 or 3 inches of the ground, a piece is then sliced from the side of the stock, and the scion is similarly sliced. An oblique cut is made near the upper part of the stock, and a corresponding cut is made in the scion, forming what are called tongues, and these fit into each other. The barks of the scion and stock are carefully adjusted; they are then bound together, and clay or grafting-wax applied, to which the soil is usually drawn until all is covered except the scion.

Crown-grafting is usually resorted to in the case of aged trees, when it becomes desirable to change the variety. This mode of grafting is performed by cutting the stock horizontally across at the desired height, then cutting through the bark in a vertical line or lines, in number according to the size of the stock, slightly raising the bark, introducing the prepared scions between the wood and the bark, with their cut sides fitting to the wood, binding all together tightly, and applying grafting-clay in the usual manner.

Cleft-grafting is performed by cutting the stock horizontally across, and making a vertical cut to the depth of 2 or 3 inches. Introduce a wedge to keep the cleft open until the scion is fitted in, when the wedge must be withdrawn, a bandage applied, and the parts covered with clay or grafting-wax.

Side-grafting is practised in cases where it is not expedient to head-down there stock, but where it is desirable to keep up or to restore the regularity of the branches or fruit spurs. Choose scions in form somewhat arched or bent, cut the lower part in a long slant, and in those parts of the stock where it is desired to produce a branch or spur, cut a horizontal notch penetrating the wood to some extent. From this notch downwards make a vertical incision some 2 inches in length, penetrating to the wood; slightly raise the edges of the bark and introduce the scion, with the cut surface next to the wood of the stock; then bind carefully round, and apply grafting-wax or clay.

Shield-grafting or Budding.—This method is so universally understood and practised, that to attempt to minutely describe the operation would be a waste of time. By this method many sorts of fruit trees, Roses, &c., are increased, and it may be successfully practised from the beginning of July until the end of September. Moist and sunless weather, however, is most conducive to the success of the operation, which is performed as follows:—Take a young shoot—that is, a shoot of the current year, of the variety intended to be budded, having visible buds or eyes in the axils of the leaves; cut off the

greater part of the leaf, cut off a slice of bark and wood about 1½ inch in length, with the bud intended to be used in the middle; carefully separate the bark from the wood, avoiding at the same time in any way injuring the bark which contains the bud, and which, from its form, is usually called the shield; and insert the latter in the stock as follows:—Make a vertical slit through the bark, about 1½ inch in length, and a cross cut at the top; then with the sharp end of the handle of the budding-knife raise the bark on each side, and carefully insert the shield, cutting off that part of the top which does not rest upon the alburnum, or newly-exposed wood of the stock, by again passing the knife over the cross cut at the top; bind firmly with soft bast or cotton, and shade from bright sunshine.

Inarching, or Grafting by Approach, has already been alluded to as sometimes taking place accidentally. It is not always convenient to adopt this system, but when it is practical to do so, it is justly considered as the most certain method of grafting, as it is not necessary to sever the scion from its parent, from which it continues to draw its support, until it can be ascertained that a union has taken place with the stock. Inarching is very easily performed, by merely paring away a portion of the scion down to the alburnum or wood, and making a corresponding wound upon the stock; fit the cut surfaces accurately, and bind them tightly together. Grafting-wax may then be used, but this is not always necessary. By this means Camellias are usually increased; the single-flowered variety, which is readily grown from cuttings, being used as stocks. This is also found to be an expeditious method of proving newly-introduced varieties of the Grape Vine, taking for stocks young growing shoots of an established Vine. After carefully paring away corresponding portions of wood from the stock and the graft, both being in a green or unripened condition, fit them exactly, and bind them tightly together, taking care at the same time to avoid crushing or bruising the immature shoots; as soon as a union is formed let the ligature be slackened or removed, and the stock cut back to within an eye or two of the junction, in order to direct as much as possible the flow of sap into the scion.

To the celebrated Mr. Thomas Andrew Knight is due, I believe, the credit of being the first to recommend and to practise the system of Root-grafting; having, no doubt, observed that the roots of many plants retain their vitality long after being separated from the other parts of the plant, and evidently only require the presence of buds to enable them to develope perfectly organised plants. Root-grafting is now extensively practised, and is found to be an excellent and very expeditious mode of increasing newly-introduced plants, such as Roses, Clematises, Passion-Flowers, &c., inasmuch as a very small portion of the kinds to be increased can be readily grafted on a corresponding portion of the roots of some of their more common or hardier congeners, and under favourable treatment they very quickly form healthy plants.

In addition to the various methods already referred to, must be mentioned the system of double grafting, from which great advantages have been derived. It is found that some of our most delicious varieties of Pears succeed but indifferently when worked upon the ordinary Pear stock, also when grafted upon the Quince; but when the system of double grafting is adopted, a vast improvement is effected in the healthy development of the delicate varieties, and a corresponding improvement in the quality of their fruit. The method usually pursued is to graft the Quince with some of the stronger-growing varieties, such as Beurré d'Amanlis, &c., as a "go-between" or intermediate stock, and on this to bud or graft the more delicate but desired varieties. An eminent English pomologist has claimed to be the inventor of this system of grafting, but it is unfortunate for the establishment of this claim, and rather a realisation of the adage, "that there is nothing new under the sun," to find that this system has been recommended by a French pomological writer of a somewhat remote period, and even practised in that country as early as the year 1700.

I am unable to say whether or not double grafting has been successfully practised with the varieties of Cherries and Apples in cultivation, but the stocks in general use for the former are the Wild Cherry and the Mahaleb. The latter, on account of its surface-rooting properties, bears a similar relation to the wild Cherry that the Paradise does to the common Crab as stocks for the Apple. For the last-named, when intended to be cultivated as standard or orchard trees, the common Crab is, doubtless, the most suitable stock; but for the more delicate dessert varieties, more particularly when the trees are intended to be grown as espaliers or cordons, the best-adapted stock is, doubtlessly, the Paradise or Doucin, or Pommier de Paradis of the French. There would appear, however, to be more than one variety of the Paradise stock in use, and there would even appear to be some diversity of opinion as to which is the true variety, "and when doctors disagree who shall decide?"

So great, however, is the influence which the stock exercises upon the scion, and the scion to some extent upon the stock, and so vast is also the influence of soil and situation on both, that the subject of stock and scion opens up so wide and extensive a field for research and inquiry, that an excellent practical pomologist, writing lately upon the subject, says that our threescore years and ten hardly afford sufficient time to thoroughly explore and investigate it.

That the stock to a very great extent influences the scion as regards vigour of constitution, and in fruit trees productiveness and quality of fruit, is not to be doubted; and that the stock and the scion cannot in any degree influence or alter the specific character of each other may also, I think, be taken for granted. But the problem yet remains to be solved as to whether or not other conditions or peculiarities than have yet been alluded to, can or cannot be produced by the influence of the one upon the other; and should it be found that the scion and the stock are really capable of producing or developing certain conditions or peculiarities in each other, it will also be interesting and necessary to ascertain whether or not these peculiarities are of so permanent a character as to be retained by a part separated from the individual plant upon which they were first produced. If this should be found to be the case, then this production may, I think, with propriety be regarded as a "graft hybrid"—that is, a distinct variety, the united production of two other distinct varieties, partaking more or less of the nature and character of each of these varieties, and produced without sexual union.

My attention was drawn to this circumstance some time since by reading some extracts from an essay "On the Circulation of the Sap," by Professor Bradley, of the University of Cambridge, and dated so early as the year 1757. This learned professor says, "We find by inarching or inoculating a variegated common Jessamine, whose leaves are edged with white, into either the plain common sort, or the Spanish Jessamine, or the Indian or Brazil kinds, that the malignity which causes the whiteness in the leaves of the first mixes itself in such a manner with the juices of the plant it is engrafted upon, that their leaves become infected or tinged in some places with white colour. If we put only a bud of the variegated sort into a plain Jessamine 10 or 12 feet above the ground, the poison will reach the branches next the root, as well as those which are at a great distance above it." It is certain, from what the learned professor says, he believed the condition of variegation, at least, could with certainty be communicated from the stock to the scion, also from the scion to the stock; and on reading these extracts, the conclusion I came to was that experimenters of that period must have been similar to their brethren of the present day—viz., somewhat inclined to jump rather hastily at conclusions, and I regarded this leap on the part of the learned professor as a somewhat remarkable performance. At the same time, it really does appear that there are authenticated cases to be pointed out, where the entire stock appears to have been infused or inoculated with the condition of variegation by the simple insertion of a variegated scion or bud. As cases in point, mention may be made of the Broadalbane Ash, the Chelsea Jasmine, &c., and also the case of a green-leaved Abutilon which had been grafted with a variegated variety, and which appears to have induced the stock to throw out variegated shoots. This plant was shown before a meeting of the Royal Horticultural Society only a few months since, and M. Lemoine, of Nancy, has also lately published an account of similar occurrences taking place after grafting Abutilon megapotamicum and A. venosum with the same variegated variety as was used in the former case—viz., A. Thompsoni.

Some time since a statement also appeared in some of the horticultural periodicals to the effect that similar results to those narrated above, had been obtained by grafting the variegated Pelargonium Mrs. Pollock upon one of the many plain or green-leaved sorts, and thinking that I might be excused for taking liberties with this family of plants, I some time since instituted various experiments with them, in order to test as far as possible the influence of the stock upon the scion, and *vice versâ*. Unfortunately, however, these experiments up to the present time have been negative as to results, or not yet sufficiently advanced to warrant the forming of decided opinions upon the subject. Allusion, however, to them at the present time may not be altogether uninteresting, and may possibly induce other experimenters to direct their attention to the matter. The field for investigation is sufficiently extensive for any amount of inquiry which may be brought to bear upon it, and in proportion to this amount will be the probability of dispelling the cloud of uncertainty which at present rests upon the subject.

In my endeavour to produce the condition of variegation in the stock, I have grafted several varieties of the plain or green-leaved Pelargoniums with sundry sorts of the Gold and Silver-variegated kinds, and to try to produce variegation in the scion I have grafted green-leaved sorts upon different varieties of the Gold and Silver-variegated kinds. To try the possibility of transmitting or reproducing the quality of *scent*, I have grafted the highly-perfumed sorts, such as tomentosum upon green-leaved Zonals, and also upon variegated Zonals; likewise many of the plain and variegated Zonal varieties upon sundry sorts of the highly-scented Cape species. Anxious, also, to ascertain what might be the influence of the stock upon the scion in a family of plants not usually treated in the manner I am about to describe, I intruded my inquiries into the family of Leguminosæ. I have in various ways experimented on sundry members of that esteemed family, grafting green Marrow Peas upon the early white varieties, and early white sorts, such as Sutton's Ringleader, upon green Marrows, such as Yorkshire Hero, &c.; the white Mazagan Bean upon the Large Green Windsor variety, and the Green Windsor upon the Early Mazagan; Fulmer's Early Dwarf Kidney Bean upon the common Scarlet Runner, and the Scarlet Runner upon several varieties of the Dwarf Kidney Bean, and all of these grafted legumes are at the present time growing freely, with possibly a perceptible diminution of vigour on the part of the Scarlet Runner, which also evinces a disposition to emit roots immediately above the point of union with the stock. The seeds which

may be produced by these grafted legumes I shall carefully preserve, with a view to hereafter sowing them at the same time and in juxtaposition with seeds of the respective sorts not so treated; and I shall carefully note any deviation, if such there should be, from the normal type, as regards the period of maturity, habit of growth, colour, and quality of seeds, &c. It will be observed that these detailed experiments have been instituted mere with a view to obtain, if possible, visible or easily-recognised results, should any such be produced, than in expectation of developing improved varieties.

To successfully perform the operation of grafting upon such fragile subjects as the common garden Pea, Kidney Beans, &c., requires a steady hand and a very sharp penknife, and I will in as few words as possible describe my mode of proceeding. About the middle of March seeds of the sorts intended to be operated upon were sown in very light soil, in seed-pans, and placed in a temperature of about 60°. In six or eight days most of the sorts were sufficiently advanced to be grafted, and on freeing the young plants from the soil in which they had vegetated, the plumules or stems were found to be some 2 or more inches in length, and the radicles or roots of similar, or rather of greater length. The latter were left intact, care being taken in no way to injure them. Selecting two varieties intended to stand to each other in the relation of stock and scion, with a sharp penknife a slice was cut from the side of the stem of each, to the depth of nearly one-half the diameter of the stems, and about an inch or mere in length, commencing the slice at about half an inch from the cotyledons. The wounded sides of each plant were fitted to each other as accurately as possible, and bound together with a thread of soft bast, and the plants immediately potted in small pots, and placed in the same temperature as that in which they had been started into growth. They did not appear to have received any check or injury from the operation, but continued to progress rapidly, and at the end of five days they were placed in a cold pit; at the end of another five days they were again shaken from the soil in which they had been growing, the ligature was carefully removed, and in most instances a union was found to have been formed. It was now necessary to decide as to which variety should act as stock and which as graft or scion, and with a sharp knife the stem of the plant intended to be the scion was severed just above the cotyledons, thus entirely preventing it from deriving any benefit from its own roots, and rendering it wholly dependant upon the roots of the stock for its support. The stem of the stock was also pinched back to the leaf immediately above the union, in order to throw as much as possible the flow of sap into the scion, without, however, entirely depriving the stock of its foliage for a short time longer. The plants were again repotted and placed in a close atmosphere, in a temperature of about 60°, where they remained for a few days, when the stocks were cut back close to their junction with the scion, and any attempts on the part of the latter to emit roots into the soil were effectually checked, and the plants were now placed for a time in a cold pit before being finally planted in the open border.—P. Grieve, *Culford*.

HORTICULTURAL EXHIBITIONS: THEIR INFLUENCE ON GARDENING.

Everyone who attentively observes the current of passing events must have noticed that the present is essentially the age for exhibitions, whether we take those wonderful productions of the mechanician which, on the one hand, are composed of parts so minute and delicate as almost to rival the web of the spider; or, on the other hand, those ponderous machines, such, for instance, as a thousand-horse-power marine engine, the contemplation of whose gigantic powers is almost enough to take away the breath. In fact, almost everything that is in request, whether an object of use or of luxury, has to undergo the ordeal of competitive exhibition. And who is there who has not noticed the progress that has been made under the all-powerful incentive of this commendable and friendly rivalry which these exhibitions, of whatever description, have awakened, not only in those who take an active part in them as exhibitors, but in the far greater number who go either to gratify a feeling of curiosity, or with a disposition to learn? If we take a broad view of the matter, we see the wonderful influence that the Great International Exhibitions of 1851 and 1862 have had upon almost all things in everyday use. If these views are correct as to things in general, they are equally true as applied to matters connected with horticulture.

The cultivation of the fruits of the earth being the first occupation that man was engaged in, it follows that in remote ages some cultural knowledge must have existed, at least in so far as related to those things connected with his immediate wants. Of this we have evidence in the knowledge of the cultivation of the Vine possessed by the inhabitants of ancient Greece and Rome. Nor was their knowledge simply confined to the essentially useful, for we have evidence of their appreciation of the beautiful in vegetable forms, from their adoption of the wreath of Laurel to crown their greatest warriors and the champions in their athletic games. And here I may observe that no greater tribute could possibly be paid to horticulture than that, even amongst heathen nations—as evidence, pagan Greece and Rome in past ages, and the Chinese of the present day—the more civilised they are, the greater their knowledge and love of horticulture. The more humanised, civilised, cultivated, and refined an individual or a nation may be, the greater will be his or its love of horticulture, which in its turn is a most powerful means of improving, expanding, and elevating the minds of all who come within its influence.

There are two things necessary for the advancement of horticulture in any country—peace and prosperity. For the last fifty years with little interruption we have enjoyed these blessings, and during the time the advance made in most of the branches of horticulture has been very great. This in a great measure is traceable to the establishment of horticultural exhibitions, not only as seen from a cultural point of view, but also as causing the introduction of great numbers of new plants from every country where any could be obtained, which can be grown either in the open air, or with the assistance of these appliances in horticulture which have so greatly increased and improved in the present generation.

There can scarcely be a culinary vegetable named but has, by discriminate seed-saving, or skilful crossing or hybridising, been so far improved as to be vastly superior to its progenitors. Considerable improvement has also been effected in some varieties of fruits. In what are known by the name of florists' flowers, great numbers of plants that in their normal condition were quite insignificant, have, under the skilful manipulation of the hybridist, been so much improved as in many cases to leave little more than a faint trace of their origin. Many of these plants represent the most beautiful forms and colours, are of the easiest possible culture, and proportionately cheap, consequently within the means of thousands who love flowers but cannot afford to spend large sums in their purchase.

Within the last thirty years the demand for new plants has been so great, that almost immeasurable tracts of both the eastern and western hemispheres have been explored by plant-collectors, whose exertions have been rewarded by the discovery of great numbers of plants. In the Celestial Empire, Japan, India, Central America, and the far-distant regions of Australia and California, thousands of miles of territory previously unexplored by the botanist, have rewarded his labours by yielding up hundreds of plants of the most useful or beautiful description, from the mighty monarch of the Californian forest—the Wellingtonia gigantea, to those exquisitely beautiful Orchids which have been introduced of late years in such numbers from the eastern and western hemispheres. These and other advances which have been made, especially the wide extension of the most approved methods of cultivating almost every variety of fruit, flower, and culinary vegetable, are mainly due to the influence of horticultural exhibitions, which, on a comprehensive scale, were first brought into existence by that Society which we ought all to look upon as the parent of horticulture as it exists in this country—the Royal Horticultural Society of London. The example set by the Royal Horticultural Society has spread far and wide to almost every provincial town and village in the kingdom, until horticultural gatherings have become, especially in many of the great manufacturing centres, equal as examples or exponents of the horticulture of the present day to the great exhibitions held in London; and the numbers of people who attend at and profit by them greatly exceed those who attend the exhibitions held in the metropolis.

In looking at the actual state of anything, we are apt to lose sight of the means by which such a state has been brought about. As I have previously stated, the general prosperity of the country for a considerable time has favoured the advancement of horticulture. The introduction of cheap glass, and the application of the hot-water system to the heating of plant structures, have had an influence on the progress that has been made. The discoveries in chemistry, as given to the world in our time by Liebig, Lawes, and others, have opened up a wide field for the consideration of the horticulturist, and have materially influenced and assisted his progress. The general diffusion of knowledge in horticultural matters through the horticultural press, and innumerable cultural treatises on special subjects—this, with a better knowledge of vegetable physiology and the geographical distribution of plants, has placed the gardeners of the present day in a position to make great progress; and I think it is not too much to say they have shown themselves worthy of the opportunity. It would ill become us by unduly lauding the horticultural progress of the present day, to reflect on what has been achieved by those who have preceded us. Such men as a Speechly, Knight, and numbers of others, would be an honour to the profession at the present or any future day; but it is in the great numbers of the present day who are able to accomplish something meritorious wherein the decided advance has been made; for with the single exception of landscape gardening, which was well known and carried out in times past, all other branches of gardening have made great progress. But when we have awarded to each of the causes named its fair share in promoting the present condition of horticulture, still it is to the influence of horticultural exhibitions that we must look for the great progress that has been made; it is there that hundreds of people possessing means first acquire those tastes which lead them to become votaries at the shrine of Flora. It is there that the experienced gardener can always see something better grown than hitherto, and which awakens in him a determination to equal or exceed that which is before him. It is there that the young men of the present day, and in whose hands will rest the horticultural reputation of this kingdom when they who bear the burthen and the toil of the present time shall have been removed from the scene of their labours—it is there that both old and young can compare notes, exchange ideas, and observe the improvements in culture, the improvements in the thousand-and-one subjects of the vege-

table kingdom which come under the charge of the gardener. It is there that the gardener will always see something calculated to remove those little conceits which we all, perhaps, entertain for our own performances, and where all in common can contemplate the most beautiful of Nature's productions.

I have noticed that there is a danger of exhibitions in some places becoming mere floral displays of a few specialities. As such, they are all that could be desired; but, seen from a more essential point of view, they are a great mistake. There is one thing that ought never to be lost sight of: that although it is desirable to render them sufficiently attractive for the greatest number, still it is of equal or greater importance to render them thoroughly comprehensive by including all varieties of plants, flowers, and culinary vegetables that are worthy of cultivation. If these views are correct, it behoves every well-wisher of horticulture to assist by all the means in his power the encouragement and promotion of these exhibitions.—T. Baines, *Summerfield, Bowdon, Manchester.*

DOUBLE PELARGONIUMS.

I shall be glad to know if any one is trying this new class of Pelargoniums for bedding purposes this season, and with what success.

Gloire de Nancy was well spoken of by the authorities at Chiswick last year, but now that we have dwarfer kinds, that variety must necessarily give way. I have a long line of the Double Tom Thumb (Madame Rose Charmeux), and am greatly pleased with it. I consider it even dwarfer than the old Tom Thumb, and much more free-blooming; its colour, however, is not so bright, but, nevertheless, very rich and effective. It is, in fact, a very good semi-double—for it is by no means a full double—counterpart of its popular namesake. Its blossoms, as in the other double kinds, instead of falling, dry on the truss, and require picking over every day or two. Finally, they do not suffer in the least through being battered about by the rain.

A few days ago I was told by an excellent authority that by judiciously thinning-out the flower buds forming the trusses of double Pelargoniums, the blooms become much larger, and the heads of flower attain Hydrangea-like proportions; this is quite feasible, and I have put aside a plant of each kind to experiment upon.—Gulielmus.

GARDEN versus SHOW ROSES.

The Rev. W. F. Radclyffe has rendered an essential service to rosarians in drawing a broad thick line between "beautiful Roses for garden ornamentation" and "exhibition Roses." Our writers on the Rose have of late been playing too much on one string—treating the Rose as if exhibition were the sole aim of cultivators. Now, I should estimate that not more than 1 per cent. of Rose-lovers are exhibitors, the 99 per cent. valuing the Rose for its beauty on the tree in the garden. It is well known that many of the flowers seen at the shows are brought into that state by an amount of labour and garden disfigurement, by gross feeding and shading, that few but exhibitors would submit to. If the non-exhibitor should choose his varieties from the stands at the flower shows and expect to get such Roses, or anything like them without the aforesaid appliances, he would be wofully disappointed. Experienced rosarians are well aware of this. Such generally choose their Roses from the trees in the Rose nurseries, or in the gardens of their friends. Further, it would be an essential aid to non-exhibitors if Rose-growers would mark in their catalogues such kinds as are only exhibition Roses.—William Paul, *Paul's Nurseries, Waltham Cross, N.*

THRIPS ON AZALEAS.

Having read Mr. Baker's paper on the Azalea, I felt rather disappointed to find that he said nothing about the insects which infest it, and keeping it free from these I think is one of the greatest points in Azalea culture; for where is there a plant that is more subject to thrips?

When I came to my present situation, which was in September, I found about four dozen Azaleas in a new vinery, but what objects they were—young Vines and all! I found Gishurst compound just on the shelf, and I soon sent off for some tobacco. I dissolved the compound as directed—viz., 4 ozs. to the gallon, in a large tub; I then dipped the plants in it, and was careful to wet every part of them. I then syringed the Vines with the same solution between three and four o'clock; in the evening I well filled the house with smoke. On the third day I repeated both processes again, and am happy to say they produced a complete cure. I smoked on each occasion as long as we could stand in it—about five minutes at a time. The plants were kept in the same house for perhaps two months afterwards, and then put in a large airy conservatory. Just as they begin to swell their buds for blooming I apply Standen's Gardener's Friend, which has done wonders with them. It has enabled them to produce a fair quantity of bloom; the flowers were very large, considering that there was originally scarcely a leaf on the plants which was not eaten all over by thrips. After blooming, the plants were replaced in the same house where I found them at first, and I treated them just as Mr. Baker recommends, with the exception that I use Standen's Friend once a-week.

I had better state that the treatment described must not be carried out until the plants have completed their growth, as they will be likely to cast their buds, nor when they are making it, otherwise the young shoots will be killed.—J. T.

MESSRS. BARR & SUG..EN'S TRIAL GROUNDS.

There is a process technically known as "rogueing," which is indispensable to the preservation of true stocks of flowers and vegetables to be perpetuated by seed, and it cannot be carried out too severely in order to attain the desired result; for even with the greatest of care exercised in seed-saving, and where the seed-bearing plants are grown in large breadths, there is always a danger of cross-fertilisation, and the appearance of plants varying from the form to be preserved. The circumstances which have given rise to variations from a certain type may give rise to other variations either of advancement or retrogression, and it is the object of rogueing to remove all plants having the latter tendency, whilst it is the interest of the seed-grower to preserve all having the former. With this view, whenever anything promising is discovered, it is marked and taken care of; when, on the other hand, a plant does not come up to the standard, though it is still the interest of the seed-grower, and more so that of the seed-buyer, that it should be removed, this is not always done, or if done not with sufficient care, and the result is deterioration. Many good varieties have doubtless disappeared from this cause; at the same time, there is no question that with every care it is a difficult matter to preserve for a number of years true stocks, especially of such plants as Broccoli and Cabbage, which are so apt to sport and intermix. However great the disappointment which is caused by plants raised from seeds not answering, in consequence of want of care in seed-saving, to the characters which are ascribed to them, it is still worse to find that out of some fifty continental varieties not more than six or seven are distinct from each other. For this there can be no excuse; it can only arise from gross carelessness or something worse. Seed lists are already far too much cumbered with varieties which are either worthless, or so little distinct as not to be worth preserving, without increasing the multitude of names by the addition of those indicating a difference where none exists. The Royal Horticultural Society, by their trials from time to time at Chiswick, have done much good by ascertaining the comparative merits both of flowers and vegetables; and the trials being carried out with great care and strict impartiality, the results deserve, and have been received with confidence. Extensive, however, as the garden at Chiswick is—and that is the proper place to carry out trials such as those referred to—there are so many subjects all claiming attention, that it is not possible, and would not be possible even with a much larger staff, to experiment in every branch year after year; while, therefore, one mass of confusion is being cleared away another is accumulating, ready in its turn to be searched, sifted, and put in order. Seedsmen, however, are anxious to know the merits of what they sell to their customers, who are frequently, and with good reason, dissatisfied with what they receive, and accordingly some of them have trial grounds of their own to test the quality of the seeds supplied to them by growers, and to ascertain the merits of novelties. One such trial ground we visited three weeks ago—that of Mr. Barr, of King Street, Covent Garden, who has taken for the purpose three acres of ground at Tooting, and some remarks on the annual and other flowers, as seen there, may be useful. Besides these, he is testing Lettuces, Peas, Potatoes, and many other things. So numerous, indeed, are the subjects grown, that only a small proportion of the whole can be noticed here.

Taking the floral department first, among the Viscarias cardinalis is pre-eminent from the brilliancy of its colour, far surpassing the older V. oculata, pretty as it is, and being without doubt one of the most effective of all annuals. The new variety of oculata called perfecta nana, with lilac and white flowers, is a neat dwarf kind; a variety of Viscaria, or Agrostemma, cœlirosa, with rose-coloured flowers having a brighter eye and presenting a fringed appearance in consequence of the petals being variously indented, was also pleasing, but it was largely mixed with V. oculata. Of Candytufts that called Very Dwarf White answered well to its description, not exceeding 6 or 7 inches high when in flower, and being of very close habit, with neatly cut leaves. A continental novelty named the New Dwarf Lilac appeared to be a mixture of the ordinary purple and lilac; and several of the white Candytufts under various names scarcely differed from each other. Not unlike Viscaria cardinalis, and rivalling it in brightness of colour, is the splendid scarlet Linum grandiflorum. Linum narbonense, with pale blue flowers; L. Lorei, which Mr. Barr describes as having been covered with flowers of an intense blue throughout May and June; L. Lewisii variegatum, L. perenne, and perenne roseum, the last with rosy lilac flowers, are also very desirable Flaxes. Mr. Barr prefers sowing the seed of these perennial kinds in autumn. Of those beautiful everlastings, the Rhodanthes, R. Manglesii is so well known that it requires no recommendation; and there is a variety, R. Manglesii major, which, though probably of somewhat stronger growth, as grown here did not materially differ from the older kind; but R. maculata and R. maculata alba, the latter a beautiful white everlasting, may be confidently recommended to every one. Instead of coddling them in pots, Mr. Barr recommends sowing the seed in prepared beds in the open ground any time after the middle of April, either where they are to remain for flowering, or to be transplanted. Atrosanguinea, darker in colour, is also very pretty, and is not so robust in growth as maculata. Another everlasting which can be recommended is the golden-flowered Helichrysum brachyrhynchium. There were several others of the same family, but not in flower, as also of Xeranthemums. The latter are sown in autumn to stand the winter, and are then much finer than those from seed sown in spriog. Waitzia aurea is a rather new and pretty everlasting, but it appeared anything but flourishing. Acroclinium roseum, one of the prettiest of everlastings, must not be omitted.

The Dianthus family are grown in considerable numbers, and the older varieties of the Indian Pink appear destined to give place to those of Heddewigii, japonicus, &c., which are much superior in size and brilliancy of colour. Those who do not possess the means of wintering bedding plants, might with the different kinds of Dianthus alone form a good display, especially if the seed were sown in the previous autumn, and the plants transplanted to the beds, for then the flowers are produced earlier in the season, and are much larger than those from plants sown in spring. Among the showieet were the varieties of imperialis, laciniatus, characterised by their much-cut petals, and Heddewigii. Of the last, the subvarieties atropurpureus and striatus were very pretty, so were some of the double forms, and D. dentosus hybridus, purple and lilac, with a regularly marked centre. Dianthus deltoides, red and white, is a pretty plant for rockwork. The various forms of Dianthuses which have been recently introduced deserve more attention than they have hitherto received. Some of them are of exquisite beauty, others are most brilliant in colour, and they offer the advantage of being easily raised from seeds, and grown in any good garden ground.

Among Campanulas, Lorei and Lorei alba, pentagonia and pentagonia alba, and strigosa, were the most effective; and there were several varieties of Chrysanthemum tricolor, which from the size of their flowers and diversity of colouring, are amongst the most showy of hardy annuals. Of these aureum, Burridgeanum, atrococcineum, atropurpureum, and venustum, are very effective. Of Clarkias, the single and double integripetala varieties, rosy crimson or white, integripetala marginata, and the Tom Thumb varieties of dwarfer free-flowering habit, are good. Another good annual bearing considerable resemblance to the Clarkias, is Eucharidium grandiflorum, of which there are white and rose-coloured sorts. The following are also very desirable—viz., Eutoca viscida and Wrangeliana, blue; Fenzlia dianthiflora, very pretty, but apt to fail unless the seed bed be kept damp till the seedlings appear; Palava flexuosa, with beautiful pink flowers having a dark eye; Oxalis valdiviana, with bright yellow flowers, forming a good associate for Oxalis rosea—the last two are recent introductions by Messrs. Veitch, and the Palava will be a pretty plant for pot culture as well as for beds; Gilia laciniata, dwarfer than achillæfolia, lavender blue; Shortia californica, yellow, and free-flowering, especially if sown in autumn; Kaulfussia amelloides, and amelloides atroviolacea, both with fine blue flowers, but the latter preferable; Lasthenia californica, good for spring flowering, but not so desirable for summer; Leptosiphon androsaceus and densiflorus, of both of which there are lilac and white varieties; luteus, yellow, very dwarf and free-flowering; and hybridus, of various colours; Centranthus macrosiphon nanus, a pleasing little rose-coloured-flowered plant; Erysimum arkansanum, sulphur-coloured; E. Peroffskianum, well known; Calliopsis Drummondi and coronata; Sphenogyne speciosa aurea and sulphurea; Schizanthus oculatus atropurpureus and grandiflorus albus, the one purple, the other white; double Sanvitalia procumbens; Zinnia mexicana, yellow flushed with orange, dwarf and spreading, and besides this a number of other varieties will shortly be in flower. Lupines, Salvias, Statices, Daturas, Petunias; Ten-week, Intermediate, and Brompton Stocks; and Balsams are grown in numbers, but for the most part were not in bloom. There are also collections of different kinds of Salpiglossis, Sweet Williams, new dwarf Scabious, which is useful for bouquets, and of French and African Marigolds. Of the French Marigolds, the Superior Striped Single is very distinct. In a collection of Poppies, only a few of which were in bloom, Marseilles splendens was large and very fine.

Mr. Barr justly complains of the same plant being frequently supplied under different names, as well as of stocks of seeds being so mixed that they cannot be depended upon. An an instance of the former evil, in a large collection of Lathyrus, all supplied by one firm, he has found the plants under the names of Lathyrus azureus, hybridus azureus, and magellanicus, the same; L. Clymenum and tingitanus striatus the same; tingitanus and mauritanicus the same; and Napoleoneneis and species nova so like the preceding, as not to be worth distinguishing. As an instance of the latter evil, out of a bed of 224 Tropæolums, only 153 were true, and 71 were a mixture of various other kinds. Of the Tom Thumb varieties, cœruleum roseum, of which there was a fine bed, is quite distinct from any other in colour, and is very free-flowering, whilst of scarlet kinds, Pyramidal Tom Thumb, and Lilli Schmidt, are excellent dwarf scarlet varieties. Among very dark sorts, King Theodore was conspicuous. Of Antirrhinums, several varieties are grown, but the Tom Thumb race of various colours, the plant bushy and a foot high, was by far the most desirable for beds. One plant which we noticed formed quite a bouquet of flowers. Geum atrosanguineum and coccineum superbum, apparently the same, are good plants for rockwork; so, too, are the pink-flowered Crucianella stylosa, which continues in bloom a long time, and Tunica saxifraga. Gaura Lindheimeri, with white flowers and a pink calyx; Œnothera macrantha, with large yellow flowers; and Statice pseudo-armeria, the latter producing rosettes of rose-coloured flowers, are also good border plants.

Of plants grown for the ornamental character of their foliage there was a quantity of Golden Feather Pyrethrum, which is even more golden in its hue in winter and spring than in summer; but the object being to save seed, the flower stalks had not been cut over, as would be the case if it were grown in a bed; but it is almost unnecessary to mention a plant like this, for it is now to be found in most suburban gardens, and scarcely anything can be neater or more graceful as an edging. Solanums for subtropical effect had just been planted out, but small as they were, the characters of some of them, as in S. pyracanthum, citrulifolium, marginatum, glaucophyllum, and Balbisii were becoming apparent. Several of the Artemisias, as A. gracilis, A annua, and A. argentea, from their graceful elegantly divided foliage are suitable for the same purpose as the preceding; and Cosmos atropurpureus and bipinnatus, plants belonging to the same natural order, might even be employed for table decoration.

Mesembryanthemums were not in flower, with the exception of tricolor, rose-coloured with a dark disk, nor were the Martynias, which are here treated as half-hardy annuals; but the orange and white-flowered Thunbergias were, the plants having been raised under glass and planted out in June.

Among those showy but rather coarse annuals, the Eschscholtzias, Mr. Barr pointed out a new continental kind sent out under the name of Eschscholtzia crocea rosea, not one flower out of a thousand of which he considered came within 50 per cent of the description given. How this might be we could not say, for the bed had been "rogued" out in the morn-

ing, as many plants having been taken out as those left, the flowers of which, though certainly pretty enough, fell considerably short of the description, being of a creamy rose colour in the interior when open, and the outside of the petals rose-coloured. Linaria bipartita striata, another novelty, he states proved one-third purple like L. bipartita, one-third white, and the remainder were striped, some delicately, some more strongly. Between Centaurea pseudo-depressa, blue with a reddish centre, and Centaurea depressa no difference could be perceived here, except that the latter had somewhat larger flower heads.

Of Lettuces the samples were very numerous and interesting; and though several of them had commenced to run to seed, that circumstance could not be regretted, for it showed what kinds did not possess that undesirable tendency. Of the Cabbage Lettuces Tom Thumb stands the summer well, and would probably be a good frame Lettuce. The Malta, known also as the Drumhead, and the Neapolitan, the one light, the other of a dark green, are two of the best of summer Cabbage Lettuces. Bossin is remarkable for its great size, and is a large crisp-leaved form of the Silesian or White Batavian. The Brown Batavian is also a solid kind resembling the Malta, but the brownness of its leaves is objectionable for the salad bowl when green-leaved kinds are to be had. Longstander forms a large heart, and is slow in running to seed. Imperial is also a large firm-hearted Lettuce having the same property. Cos Lettuces are even more numerous than the Cabbage varieties, the most prominent for its quality being the Paris White Cos, generally considered the finest of all the summer Cos Lettuces. The names of the varieties or selections of it are too numerous to repeat here, and in some instances they are improvements. From the hooded character of its leaves it blanches very well without tying, but the London market gardeners generally tie it two or three days before sending it to market, more as a matter of form to please the Londoners than anything else. Covent Garden Giant Green Cos is similar to the large forms of the preceding, an excellent variety, differing from it in the leaves being greener. London White Cos is a narrow-leaved Lettuce, which turns in quickly, and is a favourite with the London market gardeners for the first crop, but is not to be compared for quality to the Paris Cos. Moorpark, a large variety closely allied to the latter, is very late in running to seed, and is altogether one of the best of the hardy Cos Lettuces. Of the black-seeded Bath or Brown Cos there are several forms, but many consider the old one the best of all. Its great recommendation is its hardiness, but when tied up it blanches well, and has a grateful nutty flavour. Wheeler's Imperial, Duckett's Perfection, Holme Park, Bearfield's Hardiest (white-seeded), Geldring's Bath Cos, and Sugarloaf are good selections of the Bath Cos, slow in running to seed, and blanching well. Sugarloaf is somewhat lighter in colour and narrower in the leaf than the others. It is an excellent variety.

Time would not allow of an examination of the Peas and other vegetables; but it may be mentioned that Laxton's Supreme Pea fully justified the high character given of it in these columns, the pods, notwithstanding the previous dry weather, being very full, and the Peas large. There was also a very prolific Longpod Bean and a collection of Beets, some ornamental by their foliage, others grown for culinary purposes, and to which the test of baking should be applied. Of the former, Henderson's Dwarf Waterloo and the Crimson-leaved were two of the best, the foliage being highly coloured and not coarse.

Among plants deserving of cultivation for their fragrance Matthiola bicornis with pale lilac flowers deserves especial mention for its delicious fragrance in the evening; and Schizopetalon Walkeri, with white flowers, is also possessed of the same property, though in a less degree. Lilium longiflorum Liu-Kiu, a superb Lily, is also highly scented, and has very large flowers.

SOIL FOR GRAPE VINES.

Mr. Cramb's paper, read at the Manchester Congress, and printed by you in page 96, is valuable as recording an observed fact—namely, that Grapes succeed in soils of the old red sandstone, but fail in magnesian limestone. I wish Mr. Cramb had contented himself with this short statement, and not added that "the caustic property of the lime has worked all the mischief, and that the nearer it approaches the state of carbonate, the more fatal its effect."

Now, in the first place, lime in a caustic state does not exist in nature. It is made caustic only by an artificial process. Secondly, carbonate of lime, or chalk, so far from being more fatal in its effects than caustic lime, is perfectly mild and harmless. It is well known that some of the best vineyards in France are on calcareous soil. From this I should infer that any injury which Vines receive from magnesian limestone must be attributed to the magnesia rather than to the lime.—G. S.

ROYAL BOTANIC SOCIETY.

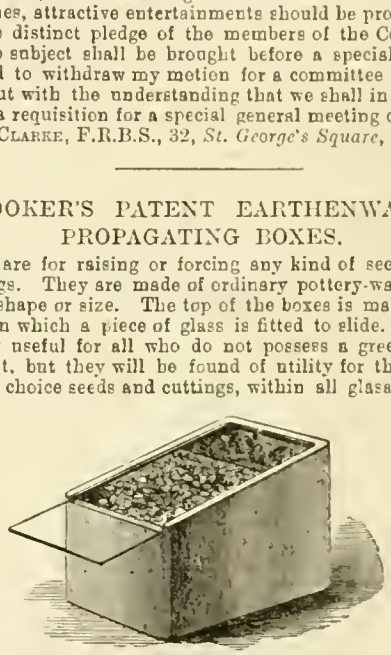
I was one of the very few who did honour to the birthday of Linnæus to-day (August 10th), by attending the anniversary meeting, and I beg your permission to state to the large body of Fellows absent, what assuredly will not be published otherwise.

Some of the Fellows perceived from the report the consequences of continuous maladministration—the falling-off on the subscriptions from £3,558 to £3,196, on the exhibition receipts from £3,100 to £2,827; the increase of the liabilities; and the diminution in the reproductive expenditure. Some comments were made on the delay, year after year, in completing the conservatory, objecting to the attempt to carry out a paltry addition by voluntary subscriptions, when it is desirable the whole work should be at once carried out by raising the amount on loan. The memorable "Special Fête" or "Reception" by H.R.H. the Prince of Teck was not forgotten, nor the way in which, by bad arrangements, the members of the Royal Family were mobbed, and it was urged that instead of a renewal of such scenes, attractive entertainments should be provided.

On the distinct pledge of the members of the Council that the whole subject shall be brought before a special council, I consented to withdraw my motion for a committee of investigation, but with the understanding that we shall in the spring draw up a requisition for a special general meeting of Fellows. —Hyde Clarke, F.R.B.S., 32, *St. George's Square, S.W.*

LOOKER'S PATENT EARTHENWARE PROPAGATING BOXES.

These are for raising or forcing any kind of seeds, plants, or cuttings. They are made of ordinary pottery-ware, of any required shape or size. The top of the boxes is made slightly sloping, in which a piece of glass is fitted to slide. They are especially useful for all who do not possess a greenhouse or forcing-pit, but they will be found of utility for the separate growth of choice seeds and cuttings, within all glass buildings.



For propagating in rooms by window-gardeners, they will be particularly serviceable. The prices do not increase in proportion to the increase of size. The air is let in at the top and is easily regulated. The glass if broken can be replaced at about a sixth of the cost (or even less), of a new bell-glass. The rainfall or other moisture cannot enter the box.

PROPAGATING THE CARNATION AND PICOTEE.

The following remarks are intended more for the amateur than the professional gardener. There are two modes of propagation—by layers and by seed. Layering is performed at the end of July or early in August. The shoot intended to be layered should have the leaves near its base removed; then make an incision with a knife from a joint in an upward direction. Many gardeners make it a rule to shear off the points of the leaves, but doing so I consider is merely following a method, and is unnecessary for the well-doing of the future plant. Soil consisting of three-fourths of good turfy loam and one-fourth of well-decayed manure, with a fair dash of silver sand, should be placed round the plants for the shoots to be pegged down upon. Keep the tongue or incision open,

before covering with the soil, so that the roots may be freely emitted. Watering must be resorted to occasionally during dry weather, till the layers are well rooted.

By the beginning of September the layers will be ready for removal, and should be carefully lifted and planted in a dry border, well drained, and if possible facing the south or south-west. Any good garden soil will suit them; but if some loam and manure be applied to the border, the application will repay the labour, &c. Wireworms must be diligently looked after when disturbing the soil at any time, as these pests often destroy many plants.

On the approach of winter, and before the frost becomes too severe, mulching with short litter to protect the plants will greatly assist them.

In propagating by seeds, they should be sown during the first week in May, in some fine soil in pans well-drained, and placed in a light cool frame. When the plants are large enough they should be planted singly out in 3-inch pots. Well-drained soil, such as recommended for layers, will do for this potting. Replace the plants in the frame for a short time to take hold of the soil and make a few roots; afterwards transfer them to an open border with a northern aspect, plunging the pots in ashes. When the pots become full of roots the plants may be planted where they are intended to bloom, protecting them during the winter in the same way as plants from layers.—Henry C. Ogle, *Welwyn.*

THE FINDERNE AND OTHER MEMORIAL FLOWERS.

The Journal of Horticulture for July 29th contains an interesting paper, entitled "Finderne Flowers," which has attracted much notice here, where several of us are cultivators of "memorial flowers."

Burke's account is a remarkable one, and having spent my early years near Needwood Forest, and within sight of Tutbury Castle, the story has a peculiar charm. Mickleover, too, and Derby are familiar names; but that which induces me to write to you on this subject is the mention of "Garden flowers grown wild, brought by Sir Geoffrey from the Holy Land," which cannot be exterminated. We should be glad to know the names of these faithful flowers, sown or set by the good Sir Geoffrey. Perhaps some of your readers at Mickleover or Derby may through the medium of your Journal be able to furnish them, and thereby help us to discover whether or no amongst our Syrian treasures we possess the "Finderne Flowers."

In 1852 my sons returned from a tour through Syria, and brought me dried specimens of flowers and seeds from the Holy Land. These seeds were sown early in the spring of 1853 in our garden at Liscard, in Cheshire, and proved to be Malva sylvestris, Medicago maculata, Convolvulus arvensis, Anagallis arvensis, Echium vulgare, Wallflowers, and a small Gnaphalium. The Wallflowers and Medicago flourished for years until we left Cheshire for the neighbourhood of London. This spring I again received a packet of seeds from the Holy Land, which were immediately committed to a prepared border; they have come up well, despite of the dry season, and are healthy, though they have not yet flowered. Wallflowers, Marigold, Trefoil, Larkspur, Mallow, Coreopsis, and a small plant I cannot yet identify—probably a Pimpernel, are now my mementos of the sacred soil whence they came, and also of the love which makes the smallest gift a perennial treasure.—Anna Harrison.

SUPPLY FROM A KITCHEN GARDEN.

I am a gardener with a small kitchen garden. The area is 52 poles; the family which I am expected to supply are eleven in number, besides company. Through June and part of July I have had enough, but lately, owing to my garden being entirely surrounded by trees which have drunk up all the moisture, my vegetables are smaller than they were a fortnight ago. Perhaps I may as well mention that the garden contains 354 fruit and other deciduous trees from 3 to 20 feet high: therefore I find that if they were distributed regularly they would make a very nice plantation at about 5 square yards for each tree, which I consider would be much too close to thrive.

What I want to know is, Is it possible for me to satisfy the wants of the family? I am always in trouble concerning my vegetables; I cannot satisfy my master, the cook, nor myself. Had I better give it up in despair, and seek a more comfortable situation, for I cannot perceive anything more comfortless than my present situation?—A Persevering Gardener.

[We cannot see how in such a limited space you can keep up a regular succession of vegetables if used at all plentifully. We think your case is just one of those referred to by "R. F.," in which it is impossible that any party can be satisfied. It is a mistake altogether to have vegetable ground encumbered with trees, as the shade in general prevents the free healthy growth of the vegetables, besides extracting, as you say, the moisture from the soil.]

RUBUS LEUCODERMIS.

In addition to the novel appearance presented by this plant through its wood being seemingly whitewashed, it is valuable as a fruit-producing shrub. My plant has occupied the same spot for a number of years without protection; it is planted on the edge of a coach-drive, at the back of which are Conifers and various shrubs, and, tied to a stout stake, it has now attained a height of 12 feet. From the base upwards it is covered with branches bearing bright orange fruit of the size of the common Blackberry, which hang in the greatest profusion. These berries are juicy and of a rich flavour, somewhat between that of the Melon and Pine Apple, and are pronounced "excellent" by the many persons who have partaken of them within the past fortnight.—Gulielmus.

THE LATE MR. WHITING.

With regret I read in the Journal of the demise of Mr. Whiting, having been acquainted with him for more than thirty years. He was, if I remember aright, a native of Weobley, in Herefordshire, and commenced his gardening career at Garnston Park, near Weobley, the seat of Captain Peploe. There can be no question as to Mr. Whiting standing high as a horticulturist, and deservedly so. While he was at Kipling, I have no hesitation in saying that I saw some of the finest Grapes that were ever grown, especially the Canon Hall Muscats: some of them, I believe, were exhibited at one of the Horticultural Society's meetings, and for which he received a medal.

After he left Kipling he went to the Duke of Leeds, at Hornby Castle, Yorkshire, but I believe he did not remain there very long. Soon after that he went to Deepdene, and there he has had a long and honourable career. He has gone to his rest lamented by a large circle of sorrowing friends.—M. H.

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

Griffinia bryades (Wood Griffinia). *Nat. ord.*, Amaryllidaceæ. *Linn.*, Hexandria Monogynia.—A native of the seashore forests near Rio de Janeiro, in Brazil. Flowers blue-lilac with white centre.—(*Bot. Mag.*, *t.* 5786.)

Phaleria laurifolia (Laurel-leaved Phaleria). *Nat. ord.*, Thymelaceæ. *Linn.*, Tetrandria Monogynia.—An evergreen stove shrub. Native of Timor. Flowers yellowish white, and very fragrant—(*Ibid.*, *t.* 5787.)

Steriphoma paradoxum (Paradoxical Steriphoma). *Nat. ord.*, Capparidaceæ. *Linn.*, Octandria Monogynia.—Native of the Caraccas and New Grenada. It is a stove shrub. Flowers orange and pale yellow; stamens very long and pale yellow. (*Ibid.*, *t.* 5788.)

Aphelandra acutifolia (Pointed-leaved Aphelandra). *Nat. ord.*, Acanthaceæ. *Linn.*, Didynamia Gymnospermia.—Native of many parts of South America. Imported by Messrs. Veitch. Flowers vermilion.—(*Ibid.*, *t.* 5789.)

Myrcia amplexicaulis (Stem-clasping-leaved Myrcia). *Nat. ord.*, Myrtaceæ. *Linn.*, Icosandria Monogynia.—A stove evergreen shrub. Native of Rio de Janeiro. Flowers white.—(*Ibid.*, *t.* 5790.)

Begonia Sedeni.—"We learn from the Messrs. Veitch and Sons, of Chelsea, who are its fortunate raisers, that it was obtained by crossing B. boliviensis with an unnamed species not yet offered for sale. It was raised in 1868, and was exhibited on June 2nd of the present year at South Kensington, where it obtained a first-class medal and certificate; and on June 30th at the Regent's Park, where the highest honours were also awarded to it. We believe that this new Begonia will prove one of the most ornamental and valuable of our decorative plants, for not only are its blossoms large, abundant, and highly coloured, but its habit is in every way irreproachable; and as it thrives well

—so we are informed on the best authority—in a temperature of 55° to 60°, which suits B. boliviensis, there can be no difficulty on the score of cultivation.

"Begonia Sedeni is a softwooded plant, with erect hairy purplish red stems. The leaves are obliquely ovate-lanceolate, tapered to a long point, duplicately serrate, of a dull green, with pale-coloured veins, and red hairs which show as a reddish fringe at the edge. The cymes are three-flowered, axillary, on reddish peduncles 4 inches long, bearing a pair of bluntly-ovate bracts subtending the three pedicels, which are about 1½ inch long. The central or larger flower is male, and has two ovate sepaline divisions an inch long, and two oblong ovate petaline ones 1½ inch long, while in the centre is a tuft of yellow stamens. The two lateral flowers are female, somewhat smaller, with five oblong segments, and three contorted yellow stigmas, surmounting a three-winged ovary, which has one of the wings prolonged. It is most floriferous, the young plants, when only 6 inches high, developing blossoms freely."—(*Florist and Pomologist*, 3rd s., ii., 169.)

COMBE ABBEY.

The Seat of the Earl of Craven.

This fine place, which has taken such a high position in the gardening world by the splendid fruit which has been exhibited by Mr. Miller, occupies a position in the midst of that level tract of country which surrounds the ancient and interesting city of Coventry. The visitor after leaving Coventry finds himself in a district purely rural in all its features, corn fields waving with the breeze alternating with pastures, with here and there a plantation of well-grown trees, showing that the fertility he perceives in the cultivated grounds results from natural influences as well as from the industry of the occupiers. Good roads bounded by hedges carry him in a south-westerly direction until he is told he has travelled upwards of four miles, and this without encountering any eminences worth mentioning. He then finds indications of his being in the immediate neighbourhood of the mansion of some wealthy gentleman; in fact, tokens of that have been visible before in the shape of schools, extensive workshops, &c. By-and-by a glimpse of the mansion is obtained on the left, and here, it must be confessed, the first impression is not good; the expectation of meeting with some monastic building, altered only internally to meet the requirements of its present occupants, is not fulfilled, neither is the site such as in most cases was chosen for religious edifices. A low secluded position in a hilly district was common enough, perhaps more so than an elevated one; but a low place in a flat neighbourhood presents but little that is enviable. On a nearer approach, however, it has a better appearance; for the eye on discerning the base of the building perceives that the position is only on a level with the ground in the neighbourhood, and the trees and rich pasture land in the extensive park attract the attention elsewhere, and confirm in some degree our notion of the prudence of the monks of old in pitching their abode where the produce of the earth would be at all times bountiful. The mansion, though not outwardly attractive, is large, and I believe fitted up with every luxury and convenience that can be desired.

In giving a rough idea of the features of this remarkable place, it may be said the carriage front of the mansion faces west, or rather the main entrance through the park is from that direction, while dressed grounds occupy the other three sides. The kitchen garden and the forcing houses are a short distance to the east of the mansion, but united to it by dressed grounds, shrubberies, &c., while extensive pleasure grounds also extend to the north and north-west sides, where a large piece of ornamental water forms the boundary between them and the park. Pleasure grounds, including a very fine croquet ground, also stretch from the mansion along the southern side of the kitchen garden, where the latter is bounded by some trees of older date, screening and sheltering the whole from the violence of the south-westerly gales. Large trees also serve the same purpose on the east and north sides; in fact, it may be said the whole is nearly surrounded by trees, excepting that a portion of the pleasure ground on one side juts out into the park, and is, consequently, more open. It must not be inferred that the shade and other influences of the old trees referred to extend where not wanted; on the contrary, they are at a sufficient distance to cause no injury to the more delicate objects they protect, while they must be of infinite service, and give the whole a clothed and sheltered appearance.

By the foregoing it will be seen that the kitchen garden is at a convenient distance from the mansion, being only separated from it by a breadth of dressed ground and shrubbery. With the exception of the large trees and some old shrubs near the mansion, the whole has the stamp of quite a new place; and so, in fact, it is. A small garden of no great importance occupied a part of the site of the new one, but that was done away with, and the present garden formed, which has in point of excellence few equals anywhere. It is of an oblong shape being longest on the east and west sides. The principal entrance is in the centre of the west end, where a singularly constructed edifice forms the gateway. Possibly this may be in harmony with some other things, but it differs from all similar openings. By it we enter upon a fine broad walk, 12 or 16 feet wide, leading straight to the east end, where Mr. Miller's cottage is, and which with some other buildings forms a portion of the east-end wall of the garden. A fine range of vineries and other forcing houses occupies the whole, or nearly so, of the north wall, and at the east end of the garden near Mr. Miller's house is a series of houses running north and south, their ends or entrances facing the broad central walk alluded to. Some of these houses stand back to back—that is, one faces east and its fellow west—and are devoted to various purposes. One house was full of flowering plants, and others were employed in forwarding plants for succession, or contained those whose flowering was over. There was a good crop of Melons in a house, which, no doubt, did much service in winter. The two structures facing the west entrance were of a somewhat imposing appearance. Peach houses, or what some call glazed walls, the glass being as high as the wall, and about 6 feet or more from it, with a sort of span-roof of an ornamental kind, presented a striking appearance from the entrance. Very fine Peaches were ripening in one of them at the time of my visit, but Mr. Miller said the crop of the later Peaches was not nearly what he expected; he, like many others, trusting to the trees setting their fruit without artificial heat, and this few have done in the present year. As it was the crop was good for the season, and the early kinds had produced most abundantly; but as your readers are likely to be most interested in hearing of Mr. Miller's Grapes, I shall at once advert to these.

On taking a cursory survey of the vineries occupying the north wall, the external appearance is not very different from that of similar houses elsewhere, only they are larger and more lofty than many, have improved means of ventilation, and are glazed with somewhat larger squares of glass than are often met with, although not by any means remarkable in this respect. The heating is by hot water, with a smaller number of boilers than in many places, but not on the one-boiler system. The glass and painting seemed in excellent order, and external neatness prepared me for the sight which met my gaze on entering, for having seen samples of Mr. Miller's Grapes at the metropolitan shows, I was expecting to find a house but thinly cropped, as is frequently the case where show Grapes are the order of the day; on the contrary, the crop in all the houses was heavy, and had I witnessed such a crop under the care of a less experienced cultivator than Mr. Miller, I should have entertained grave doubts respecting the future; but as Mr. Miller says he has had several such crops from his Vines, I must take it for granted that the present crop will be followed by others of a like kind. The crop, not of one kind of Grape only, but of all, was most abundant; even that shy bearer, the Barbarossa [Gros Guillaume] had a plentiful supply of bunches on it, and these, as might be expected, were very large.

For the information of those who are anxious to know the details of Grape management at a place in which good fruit has been supplied every day during the last six years or more, I hope Mr. Miller will give us some further information than could be gleaned by a rather hasty visit; but I may here state that Mr. Miller is no advocate of giving bottom heat by artificial means; on the contrary, he condemns it, and having for so long furnished good Grapes all the year round, he has strong grounds for his views. Other matters have also to be taken into consideration in the production of good Grapes, and there is one on which, perhaps, more depends than on bottom heat to ensure fine well-grown fruit, and that is the character of the border, which in some cases is determined by circumstances over which the cultivator has little control; but Mr. Miller's borders have been formed entirely by himself, and with a result which is well known. Let us, however, speculate how far local circumstances may have aided judicious management in producing such results as those which have been achieved.

Taking a casual survey of the district, its appearance where

cultivated, and in some measure the character of its herbage when left to nature, or, in fact, we may say the weeds, I am led to the conclusion that one of the elements said to have an important influence on fertility is certainly not very abundant, and that is lime, or what the learned call calcareous matter. This material, which at one time was thought so essential in the cultivation of the Vine, has of late years been thought not so well of; in fact, it has been broadly hinted that many of the failures in Vine management may be traced to an undue proportion of it. Now, as most people are expected to make their Vine borders of the materials to be obtained at home, mixed or amended in some way, we may fairly conjecture that Mr. Miller's borders were in a great measure so composed. Although I have known the ingredients for a Vine border brought eighteen miles, yet generally it will be found that when a district consists of a soil naturally favourable to the growth of this fruit, it is much better than when an artificial mixture has to be prepared; in the latter case we have a poor chance of so evenly balancing the ingredients which compose it, as to constitute a whole capable of meeting all the requirements of the plant it is intended to support, and in the case of Vine borders I am inclined to think the lime or lime-rubbish mania has in many cases overrun its mark; certainly, to outward appearance, the soil which constitutes the kitchen garden at Combe Abbey is not overcharged with lime, and I concluded that the Vine border was not overdosed either. Assuming it to resemble in some degree that of the kitchen garden, I would regard it rather as a stiff loam than a too open one; at least, sand did not prevail to the extent it does in the rich deep soils which border many of our rivers, the Mersey for instance, the valley of which is composed in a great measure of a dark sandy soil of considerable fertility, but possibly less enduring than the soil at Combe Abbey; in fact, there seems by Mr. Miller's report to be great "staying" powers in the soil of which the Vine border is composed. Let us now take a peep into the inside, and judge for ourselves how far the border, and the management the Vines are subjected to, are in accordance with their wants.

The vineries, as already observed, are large, as far as height and width are concerned, and some of the most important seem devoted to Grape-growing only; others, as is often the case, have a bed inside, and Pines or plants are grown as well. In the latter case the roof is not so heavily covered with Vine foliage as where Grapes only are cultivated. Separate houses are devoted to Muscats and Lady Downe's, but most of the other varieties are more or less mixed, Black Hamburgh, of course, predominating. I must again remark, that in every instance the Vines were heavily cropped, certainly more so than I should have advised, and the bunches were at least one-third more numerous than in the generality of places where good Grapes are produced; yet Mr. Miller assured me they had been as heavily cropped every year, and with the same successful result. Even the Barbarossa was yielding such magnificent bunches that I refrain from making any suggestion as to their ultimate weight, in the hope I may learn it hereafter. Other Grapes were equally good. A noble house of Muscats was well worth seeing, and scarcely less interesting was one of Lady Downe's, which, however, I should like better to see in January than in July, but in the latter month it seemed all that could be desired, though in general it is not attractive as long as Hamburghs and similar varieties are to be had. The propriety, however, of having it in a house by itself was here manifest, and a healthy, clean foliage insured a good finish-off. Even the foliage in the early house was clean, and there was a plentiful supply of laterals in robust health, less juicy, perhaps, than those in the later house, but the foliage equally green. Of course the Black Hamburghs that were just coming on were the centre of attraction; bunches large and well-shouldered, with berries as large as would be convenient for those who had to eat them, were advancing fast to maturity. Occasionally a bunch of extraordinary size presented itself, one of those aptly described as all shoulder. This feature in an overgrown bunch of Black Hamburgh is, perhaps, too much admired, as indicating extraordinary vigour; but a more shapely bunch is certainly more agreeable to look upon, and there were plenty of such in the Grape houses at Combe; in fact, plenty of both kinds.

Other kinds of Grapes were also well represented, Mr. Miller having a partiality for a white one, not so much cultivated as it deserves to be—Foster's White Seedling, which has a prettily-shaped bunch, with globular rather than long berries, and in appearance ranks high as a white Grape, of course not so large as Trebbiano, or its synonyme The Child of Hale, but much superior in flavour. Trentham Black was also in good trim; but this Grape is not a general favourite elsewhere, although good where well managed. The Alicante and West's St. Peter's were also well grown, and what were equally interesting, were some good bunches of Red Frontignan—a Grape which, by the smallness of its bunches, many growers think spoils the appearance of their other productions. New kinds were also being tried, and I believe canes of Mrs. Pince's Black Muscat Grape were in bearing; but I forgot to inquire for it. The Vines and their bunches were all in most excellent order, clean and healthy, no shanking, and any insidious attempts of red spider or other enemies to gain a footing were at once counteracted. The fruit from the earliest houses had all been cut, that in the others affording a succession, and Vines in pots were being prepared elsewhere for early forcing next year. Many of the houses contained stove and other plants, which, as specimens, might have appeared at a metropolitan show with advantage. Amongst the latter were some excellent plants of a good variety of the Willow-leaved Croton.

The flower garden proper is situated between the mansion and kitchen garden, or rather to the north of the mansion. Some excavations elsewhere had given Mr. Miller material with which to throw up banks. These were taken advantage of to plant shrubs, and lay out a series of beds, partly irregular and partly forming a regular design. At the time of my visit they were well filled, while a long border in front of the south wall of the kitchen garden was converted into a handsome ribbon border by lines of very choice plants, its height and width giving it more importance than most similar borders. I cannot state the exact length, but it could not be less than 800 feet, and the surface being level, the extent produced its full effect. In this neighbourhood was the croquet ground, almost large enough for a cricket ground. Some specimens of Conifers were also here, including some memorial trees, but the trees and shrubs were mostly at the margin of the dressed ground, leaving the large space alluded to for bowls, croquet, and other games.

The kitchen garden, it is scarcely necessary to observe, was well cropped; good order and cleanliness everywhere prevailed.

The gardener's cottage at the end of the central walk or avenue entering from the west, presents nothing remarkable in its appearance, but it is a comfortable and convenient dwelling, and I hope it may long form the home of its present energetic and intelligent occupier. Suitable apartments for the young men also exist, as well as the other offices required for a large garden establishment. Mr. Miller drew my attention to one place, and it is one to which visitors are rarely invited, yet it is as indispensable as the flower bed or forcing house, and that is the rubbish heap. The worthy writer of the "Doings of the Last Week," "R. F.," very often calls the attention of his readers to the due management of this unfashionable department; but Mr. Miller goes many degrees further than "R. F." contemplates, and I should have much liked him to have been of the party who inspected Mr. Miller's rubbish heap. Instead of an out-of-the-way place being reached, where barrowload after barrowload of the garden refuse lay scattered over the ground in endless confusion, awaiting a sort of a clearing-up day, there was a tidy, well-proportioned yard, with cow shed and milking house in it, and a milch cow and two young heifers stared us in the face, while two pigs, on whom the good things of this world had told their tale, seemed less inclined to recognise strangers; a suitable domicile for them was found at one corner, and comfort and contentment seemed to pervade the happy family, which was not complete without a due proportion of fowls. Here, then, was the rubbish; here the basketfuls of short grass from the lawn, the waste Lettuces, Cabbages, and other garden refuse were transformed into the best of manure, ready for the garden again. To say nothing of the other good things the fowls and four-footed animals furnished for the use of their careful tenders, the economy of material is highly creditable to Mr. Miller and his better half.

Coventry is the most convenient railway station for Combe.—J. Robson.

NOTES AND GLEANINGS.

One of our contemporaries is angry with us because of some observations we made last week on the Horticultural Congress held at Manchester. In making these observations it was not our intention to give offence to anybody. The Horticultural Congress, like any other horticultural subject, was one

fairly open to criticism in our pages; and if we, in common with a great number more, did not regard it with the same favour that our contemporary did, that is no reason why he should take offence. We would not have noticed the matter were it not that we are called on to answer several charges. One is that we have called the meeting a Congress when it is nowhere officially called so. If we have erred in this we have done so in good company, for our contemporary uses no other designation. Even in the paper in which he makes the complaint against us he publishes some of the essays "read at the Manchester Congress"! The other charge against us is that we opposed "the larger scheme of a Congress, which was the original proposition." We must respectfully ask our contemporary to reconsider this statement. When, in December last, we announced the meeting of a Congress, we said, "We hope it may be well attended and prove satisfactory." We are not conscious of ever having published a word that was opposed to the movement.

—— At a meeting of the English Sub-Committee of the Hamburg International Horticultural Exhibition held at the offices of the Royal Horticultural Society, South Kensington, on the 3rd inst., a letter was read from the Hamburg Committee intimating that exhibitors competing for the Queen's prize for Grapes would be required to contribute at least three bunches each. Mr. T. Fingens, a member of the Hamburg Committee, has arrived in London for the purpose of aiding the English Committee. Already several entries have been received, and among the most important are the following:—Grapes—Mr. Meredith, Mr. Hollingsworth, and Mr. Thomson, of Dalkeith; Cut Flowers—Messrs. F. & A. Smith, and Messrs. Downie, Laird, & Laing; Coniferæ—Messrs. Barron & Sons, of Elvaston Nursery; Implements—Mr. Le Butt; Boilers—Dennis & Co.; Terra cotta work—Mr. Hudspith. Another long list of extra prizes was also received from Hamburg, and it has been arranged that after the prizes have been awarded exhibitors will be allowed to affix their names and price lists to their contributions. Dr. Oscar Gossler, of Hamburg, has, at the request of the Committee, kindly undertaken to secure apartments for visitors, who may write to him direct or through the English Sub-Committee. The official distribution of prizes is fixed for the 13th of September, and a sale by auction will be held in the grounds on the 14th of September, to enable exhibitors to dispose of their goods. The English Sub-Committee have appointed as their shipping agents the well-known firm of Weatherly, Mead, & Hussey, of Great Tower Street and Chamberlain's Wharf. The Exhibition is to be opened on the 2nd of September, so that contributors have no time to lose.

—— The Metropolitan Board of Works have added another new park to the metropolis in Finsbury Park, which was opened on the 7th inst. by Sir John Thwaites, the Chairman of the Board. After performing a tedious circuit of the park, with two Rifle bands "stepping short" nearly all the way, the members of the Board, and those who took part in the procession, entered the enclosure. Sir John Thwaites then declared the park open, and, after doing so, remarked that though the space around had little to do with the district after which it had been named, it was impossible, on account of the expense, to make an open space where the ground was covered with houses; all that could be done was to preserve open spaces, where these exist, before they became covered with houses, as the whole neighbourhood of this new park soon would be. The Board had been watching with the greatest care the places which had been long enjoyed by the public, and in their efforts to preseve them he hoped they would have the support of the public. The day had long gone by when it was necessary to advocate parks and similar places as a means of improving health and of bracing up the mind and body; and he hoped that in time yet more would be added to those at present existing.

The new Finsbury Park is about 120 acres in extent, and occupies a somewhat elevated position between Wood Green, the Seven Sisters' Road, the Green Lanes, and the Great Northern Railway, and fine views are obtained northwards towards Muswell Hill, the Alexandra Park Palace forming a conspicuous object in that direction. The grounds have been laid out by Mr. Vulliamy, the architect of the Board of Works, and Mr. Alexander McKenzie, the latter carrying out the whole of the groundwork and planting. The trees and shrubs, with the exception of a few previously existing, are as yet small, but, doubtless, the ultimate effect will be good. The memorandum relative to the formation of the park, issued by the Board of Works, states that a favourite suburban recreation ground, known as Brown's Wood, or Hornsey Wood, and Hornsey House, also formerly called Copt Hall, was selected as the site for the park. The ancient designation of the estate is the Prebendal Manor of Brown's Wood, in the parish of Harringay, otherwise Hornsey. The ground has a gentle southern slope from Highgate on the west, and towards Stoke Newington on the east, and is skirted on the south by the Seven Sisters' Road, and on the east by the Green Lanes. The Great Northern Railway bounds it by a cutting and embankment on the western side; and latterly the London, Edgware, and Highgate Railway has been made, with a station adjoining the park. Certain public footpaths had to be preserved for the use of the adjacent lands, and the course of the New River is through the northern portion of the land. Since the park was formed, Parliament has permitted the East London Water Company to form a great reservoir, of some acres in extent, under the surface, for the storage of water on a high level; but as the ground will be turfed over and belted with shrubs, the public will not be losers by the arrangement. Contracts were made in 1866 for the drainage of roads, &c., the formation of roads, footpaths, and ornamental water, the erection of the entrance lodges and the gateways, inclosure palings, &c. Last year, also, the planting of the trees and shrubs was completed. The expenditure for the park up to the 30th of June, has been £97,275 3*s.* 3*d.*, or, deducting £2,577 0*s.* 9*d.* received for old materials, &c., £94,698 2*s.* 6*d.* Of this the cost for parliamentary expenses was £975 3*s.* 1*d.*; property and compensation, £54,847 18*s.* 8*d.*; professional and office charges, &c., £11,252 0*s.* 10*d.*; works, £26,814 9*s.* 2*d.*; trees, shrubs, planting, &c., £2,384 8*s.* 2*d.*; wages for supervision of works, £351 12*s.* 10*d.*; incidental expenses, £619 10*s.* 6*d.*

WORK FOR THE WEEK.

KITCHEN GARDEN.

Stir the surface of the soil among all growing crops, as it is now caked by the action of the late heavy rains. Trench or dig every spare piece of ground for winter crops. Earth-up all the Cabbage tribe sufficiently advanced, and make succession plantations of *Brussels Sprouts*, *Buda Kale*, and *Broccoli*. Prick-out the *Cabbage* plants intended for spring use in nursery beds, that they may become sturdy previous to their final planting. See that *Celery* as it advances has every attention as regards weeding, the removal of offsets, and earthing-up; but in no case let the earth be raised so high as to injure or choke up the heart of the plant. Sow a small quantity of *Cauliflowers* for hand-lights; those to be wintered in frames may be sown eight days later. Plant a considerable breadth of *Endive* and *Lettuces*, and make a sowing of the latter for standing the winter. The black-seeded Brown Cos and Hardy Green are very good for this purpose. Sow Tripoli *Onion*. *Ash-leaved Kidney Potatoes* intended for seed may now be taken up, and exposed to the sun till they are green. Should the disease attack the other early sorts, let them be taken up at once, dried, sorted, and packed in dry earth or charred material. Now is a good time to make a good-sized plantation of *Savoys* for late-autumn use. Trench, manure, and dig a piece of well-drained soil for *Winter Spinach*.

FRUIT GARDEN.

Commence layering Strawberry runners in small pots for forcing. Pot for early forcing as soon as they are well rooted, and place the plants in a situation fully exposed to air and light, setting the pots on coal ashes to prevent worms entering. The following are among the best kinds for forcing:—Black Prince, Keens' Seedling, and May Queen for early forcing; Ingram's Prince Arthur, Sir C. Napier, and Oscar for later crops. Gather Pears and Apples as they ripen.

FLOWER GARDEN.

The propagation of all the more important bedding-out plants must be pushed on as quickly as possible. Late-struck cuttings are difficult to keep through the winter, owing to their having an insufficient amount of roots, and the wood being badly ripened. Let Scarlet and other Pelargoniums struck in the open ground be taken up and potted as soon as they have made roots; they will require a close frame for a week or two, when they should be placed on a dry bottom in a southern exposure to harden them for the winter. For the same purpose Verbenas, Petunias, &c., struck in pans and intended to be wintered in these, should be placed in a similar situation, at the same time stopping the points of the shoots. It should, in fact, be a point to keep them as hardy as possible by fully exposing them until they are placed in their winter quarters.

Mignonette, for winter and spring flowering, may yet be sown. Phloxes and other herbaceous plants will now be making a tolerably good show. Hollyhocks are in general great favourites, but they do not afford cuttings freely, and are in general over-plentiful at most places. These should, therefore, be examined often in search of any cuttings which they may afford, as those rooted about this time will make strong plants for next season. Attend to the tying-up of these and Dahlias, and go over the masses of Verbenas frequently for the purpose of regulating the growth, so as to keep it orderly and neat. Sow Ten-week and Intermediate Stocks for spring flowering; transplant Brompton and Queen Stocks, and if the situations in which these are to flower are not at liberty, prick them out in nursery beds, allowing them plenty of room to prevent weakly growth.

GREENHOUSE AND CONSERVATORY.

Examine the stock of pot plants in the conservatory, in order to see that none is suffering from want of pot room or other attention necessary to assist them in making young wood for flowering next season; also see that proper care is bestowed on late-growing plants in borders, for while in active growth more water will be necessary, and insects will be more troublesome than on plants at rest. Look after Luculias, and keep them clear of their great enemy black thrips; give them plenty of water at the root, and an occasional supply of clear weak manure water may be given to old plants not growing freely, until they have made plenty of wood to ensure a good display of flower. Manure water must not, however, be given to young specimens in vigorous growth, as in that case it would induce too gross a growth, a condition in which they seldom flower profusely. In order to secure fine heads of bloom from this plant it should be allowed a few weeks of comparative rest, after, say, about the middle of next month, keeping the roots rather dry, and exposing the plants as freely to air as can be done without injury to the foliage or the health of their neighbours. Brugmansia sanguinea is also a useful plant for flowering in winter and early in spring, when managed so as to have it pruned, rested, and starting into growth about this time. See that large specimens are not allowed to become too dry at the roots after they have set their buds, for the shedding of the latter is due to this cause. Young vigorous plants, however, frequently require to be watered rather sparingly at this period to prevent their making a second growth. Cinerarias for early flowering should now be growing freely, and should be shifted when necessary, for if they are to form large specimens for flowering in winter they must not be permitted to sustain any check. Remove suckers whenever they can be obtained, and pot them for spring flowering. Calceolarias will now be beginning to demand attention. Have cuttings of favourite sorts rooted as soon as possible. Seed may also now be sown in pans placed on a gentle hotbed. Let the stock of Begonias have another shift, if not already in pots sufficiently large. Keep the pots at a sufficient distance from each other, in order that the foliage may be kept from injury. Crowea saligna and Plumbago capensis are both valuable autumn-flowering plants, and the latter is almost indispensable for cut flowers. Attend to Chrysanthemums; water freely with liquid manure; good specimens should be aimed at rather than a few fine blooms. The earliest winter-flowering Heaths and Epacrises should now, or soon, be placed under cover, as it will forward their blooming. Give air, however, freely. The potting of Hyacinths, Narcissuses, &c., for forcing must soon occupy attention. About equal portions of good fibrous loam and decayed leaf mould, with silver sand, will be the best soil for them if for forcing, but well-decomposed cow dung must be substituted for the leaf mould when the bulbs are intended for late flowering. After potting place them on a dry bottom, and cover the pots 2 or 3 inches deep with old tan or ashes, preserving them at the same time as much as possible from heavy rains; under this treatment they will fill their pots with roots, and be in readiness for forcing when wanted.

PITS AND FRAMES.

Take every opportunity to collect soils of different sorts for winter and spring use; for although a few sorts of soil will suffice for all operations, yet in spring, when early Potatoes, Kidney Beans, Cucumbers, Melons, early Peas, and a number of other crops have to be grown, if a good quantity of dry soil is at hand it is of the utmost importance. A back shed may be filled with different soils put together at this season in a dry state. Collect everything that will make a compost, and have the different heaps numbered, so as to know in spring what they are—such as old Cucumber and Melon soil, plenty of decayed leaves, rotten dung, deer dung, rotten cow dung, road and river sand—indeed everything which can be collected.—W. Keane.

DOINGS OF THE LAST WEEK.

Allotment Gardens.—Writing last week of Potatoes and Peas reminds us that now and onwards are trying times for testing the neatness and continued energy of holders of small pieces of ground. We think but little of good cropping and neatness everywhere observable in the spring and early summer months. The neat clean path up to the cottage door, the well-trimmed flower border, the neatly-staked Peas, and the well-rounded rows of Potatoes, and well-thinned Onion beds, are only in keeping with the budding of the year, the singing of the birds, and the sports of the tambkins. But as autumn comes on, it too often brings with it an enervating influence. The bread-winner of the house comes home wearied and tired, and he has not such a keen eye for the weeds and what is decaying as he had in the spring—more need that others at home, however young, should put their little hands to the work and be taught to do so. As there is something joyous in what is progressing, so there is something melancholy in looking on the decaying. Too often in autumn the path choked with weeds takes the place of the bright one in spring, and withered tops of Potatoes, and dead and dying Pea haulm meet the eye, instead of something making progress and growth for future usefulness. Now, such sights should rarely be seen, and for as short a time as possible, as no sooner is such a crop taken than it ought to be followed by another.

Here, again, we would notice the superiority of the garden near the house over the allotment at a distance. In the garden near the house every drop of dirty water, dish-washings, &c., all come in useful, and for fresh-planted crops are much better than clear water, and the earth is so grateful for what is thus bestowed upon it, that it soon absorbs all those qualities that might be noxious, becoming thus the best of all disinfectants. Stronger waters must be mixed with pure water, that the roots may absorb them without injury. A puddled hole, or an old barrel sunk in the farthest-off part of the garden may thus be most useful and profitable, when it is not convenient to use the liquid at once; and all solid matters should be kept in a heap, and sprinkled frequently with a little earth to keep in all the nourishing, fertilising properties. Every withered Cabbage leaf, every bit of Potato haulm, may thus be made to return to the soil what it has taken from it, and there are few cottages from which these valuable manure-dressings may not be accumulated. Now, much as we approve of moderate-sized allotments, even though these be at a distance from the homestead, they will never compare with the garden close to the cottage, as much cannot so easily be made of the refuse of all kinds that comes from the home. We are much pleased with two things connected with cottage gardens and allotments. First, that these are better kept and managed throughout the year than they used to be, so that want of thrift and want of tidiness are less observable in the autumn than formerly; and secondly, where societies are established for promoting well-managed gardens, it is beginning to be a more general system not to examine these plots once or twice, but three or four times in the course of the year. The natural flagging energy of the autumn is thus kept up to something like the buoyant energy of the spring. All of us cultivators need a little of this reminder, otherwise it will insensibly creep upon us. We would also suggest that in all competitions between the holders of allotments and gardens, rather more should be expected from gardens near the house than from those considerably removed from it. The next time we are a few hours from home, we shall be glad to see no festering Potato tops and no withered Pea haulm, but the ground turned over afresh and filled with something that will help to fill the pot in winter.

Some time ago we made remarks on the allotment system, and now, as then, we hold that allotments are useful to a working man, chiefly when they are as large, and not larger than he and his family can cultivate well without losing time at the regular daily labour. Except in the case of jobbers, whose time is to a considerable extent at their own disposal, a piece of ground so large as to require the occupier to be several days or weeks from his usual day labour, is a very questionable advantage. The earth is still a good paymaster, but we have long been convinced that to make the most of it, a man must either have enough of it to keep him constantly employed, and

thus become a small farmer, or he must have no more than can be managed without breaking in on his usual avocation. When days or weeks are wanted, there generally springs up a feeling of dissatisfaction, as the man might be the most useful to his general employer just at those times when he would wish the most to be on his own holding. Granting, too, that when a man reaches his home and is refreshed, he will work with a zest for himself and family, such as he could hardly be expected to do in such long hours for an employer, and more especially if the garden or the allotment furnish employment different from that of the day; still, the feeling is apt to arise, that the man who is extra industrious for long hours night and morning is not in the best position for putting forth due physical energy during the day. As a general principle, very long hours of labours are a mistake. A great amount of work may thus be gone through in a short time when the practice is resorted to but seldom; but where it becomes a matter of custom, as in the hay and corn harvest, the advantages are very problematical. When, in an emergency, we have had two or three hours extra labour and paid for it, we always found that if long continued the advantage ceased. The human machine, like other machines, can only with advantage do a certain amount of work. Hence, in relation to the case in hand, we have known an allotment of a quarter of an acre prove of great value to a man and his family, but it ceased to be an advantage when he had half an acre or more, as then he had either to hire labour, or lose time himself, and that led to unpleasantness between him and his regular employer.

Who is an amateur gardener? This question, apparently a simple one, is frequently a cause of much unpleasantness in country horticultural societies. It is well in all such cases that the outlines of classes should be clear and distinct, so as to prevent all dispute. The holders of the smaller allotments, and of cottage gardens, generally compete together as cottagers, in whatever occupation they may be employed during the day; but in places where gentlemen's large gardens abound, it is found desirable that the labourers in these gardens should compete by themselves, and not with other day labourers, as many of these garden labourers from long practice may well be looked on as gardeners, and, therefore, as having greater advantages than other labourers. Mechanics and artisans also sometimes form a separate class, as they are presumed to have greater means at their command than the agricultural labourer. Very often all these compete together under the name of cottagers, and it will at once be apparent not quite on equal terms, but if in one class, the judges can look at nothing but the merits of each case. The disputes on this, however, are seldom so keen as about the amateur class. This is partly owing to the fact, that our great metropolitan societies chiefly recognise two classes, nurserymen or tradesmen, who cultivate for sale, and amateurs, including gentlemen and gentlemen's gardeners. In most country shows there are the classes for nurserymen, gentlemen and gentlemen's gardeners, amateurs, and cottagers, and it is this amateurship that creates the difficulty. Not long ago, some gardeners who exhibited successfully as gentlemen's gardeners were very much annoyed because their superior productions were disqualified from taking a prize in the amateur class. It would be well, then, if a broad deliverance were given on the subject, and then exhibitors and judges would never come into unpleasant collision. Were we to define the term amateur as generally understood, we should say that an amateur was a person having a taste for a particular art or science, yet not professing nor being dependant for a livelihood upon it. In this general definition our large societies include all who have gardens and gardeners, from noblemen to bankers and wealthy tradesmen. But when in the country societies there is a distinct class for all the above, and a separate class for amateurs, we are forced to add something to the above definition as applied to gardening, and our opinion is, that under such circumstances a man, however fond he may be of gardening, ceases to be a mere amateur when he employs another person *constantly* to assist him in his favourite pursuit. So long as he lives by other means, makes gardening a hobby, does the work himself, or merely obtains occasional assistance, he is an amateur; but when he employs a man constantly, no matter whether he calls him labourer or gardener, then he changes the class in which he must exhibit. We ourselves should be inclined to keep so much to the general definition as given above, as to take out of the amateur class the man who made a marketable affair of his hobby. According to country practice, he would then cease to be an amateur. We either want to do away with this class, or have a more defined nomenclature, and we propose for consideration that where such distinct classes exist, an amateur shall be a person who prosecutes gardening chiefly for his own enjoyment, and without any except occasional help. When he employs a man constantly, he must compete with other gentlemen and their gardeners. We shall be glad if our readers will state their opinions.

KITCHEN GARDEN.

The work has been to a great extent a repetition of that of previous weeks—planting Greens, &c., in every piece of vacant ground, the showers being a great advantage, as the ground where hard-cropped is exceedingly dry. Cleared the stools of Celery, removing every incipient sucker, tying-up previously to earthing-up the earliest. Though not allowed to be dry, owing to mulching, the bulk of the Celery has not grown very vigorously, but it is now pushing rapidly in the cooler days and longer nights. The worst of the dry season is now past, and we may now be tolerably certain of having enough of moisture. We took up a lot of the last of the autumn-sown Onions, and exposed the root ends to the sun before housing. We expect that our spring Onions will yet grow considerably, though they made no progress in the dry weather. A few tops are acquiring a yellowish tinge. Could we have flooded the beds six weeks ago, the crop would have been splendid; as it is, it will be good. Cauliflowers we never had finer; a few only of the earliest had greenish, loose, flowery heads, and the cause was wholly unknown to us, as all were treated alike. At the present season there is often apt to be a glut, and sometimes a short interval between the successions; this can be prevented by taking up some of the plants when the heads are firm and not fully swelled, removing all the leaves, except a few small ones round the head, and cutting the stems so as to leave 6 or 8 inches below the heads, and inserting the stems upright in damp sand in a dark place. In this way the late Mr. Crockett, of Raith, used to keep Cauliflower during most of the winter. Even now this is a much better plan than taking up the plants, and either hanging them up or laying them in "by the heels."

FRUIT GARDEN.

Continued summer-pruning wall trees, dwarfs, and standards. The fruit of the Apple where at all thick falls considerably, though we think a good crop will be left. We find that the roots are not so moist as we could wish, but as yet we have not ventured on watering them, and we trust they will soon have enough rain water. Our Raspberries, though bearing freely, have suffered from last summer's drought, as the canes were much smaller than usual, and some died away. We never wish to pass such another summer as that of 1868 in a garden, and feel powerless from the want of water. Even some hardy trees show the effects of the parching, though in general the foliage of forest trees has been fine, especially of all deep-rooting trees, as the Oak.

Besides attending to Peach houses, vineries, and especially orchard houses, with water, we have potted a number of *Strawberry plants for forcing*. A few details may be useful for beginners. 1st, Of pots, we prefer what are called 40's and 32's—that is, 5 or 6-inch pots, to larger pots, which are apt to encourage too luxuriant growth. These pots, if new, should be soaked, and then allowed to dry before using them. All old pots should be well washed and dried before being used. 2nd, The soil should be loamy rather than sandy, and enriched with about one-sixth part of rotten dung that has been well aired and sweetened before mixing. 3rd, At potting the crown of the plant should be little below the rim of the pot, as it may be expected to sink a little. 4th, The soil should be made very firm. The fingers will not make it firm enough—a small stick will be necessary to beat it round the plants. Bear in mind it can scarcely be made too firm. 5th, When the plants are potted the pots should be set on a hard bottom, and the plants exposed to all the sun possible. If they flag a little under the sun a slight syringing over the foliage will be better than shading. As soon as the roots begin to reach the sides of the pots rich top-dressings and manure-waterings may be freely given. During a showery autumn a sprinkling of soot on the surface will be advantageous, or any other rich manure; but if good guano is used, a very small pinch of it between the fingers will be enough for a pot.

ORNAMENTAL DEPARTMENT.

Here we have been very busy; potting, fresh-arranging, keeping lawns and walks in order, and trimming and training plants in flower beds, though we generally allow the plants to assume their natural mode of growth. Pegging down, besides the time and labour involved, is often prejudicial to the plants when prac-

tised early. Many a plant will pass a cold night unscathed if its natural upright growth is not interfered with, but which would have been greatly injured if its stems had been exposed to free radiation. We pegged down a line of Purple King Verbenas too soon, and they suffered considerably, when other lines left upright did not suffer at all. The Purple King is now fine, but it would have been finer and earlier if we had either not pegged down at all, or done so a month later when the weather was warm.—R. F.

TRADE CATALOGUE RECEIVED.

W. Cutbush & Son, Highgate, London, N.—*Bulb Catalogue for* 1869.

COVENT GARDEN MARKET.—August 11.

The supply of soft fruit has considerably diminished, Strawberries and Raspberries being nearly over, and hothouse fruit, such as Peaches and Nectarines, becoming scarce. A fair amount of business is being done in rough produce. Potatoes are good, and remain at former quotations.

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Jonrnal of Horticulture, Cottage Gardener, and Conntry Gentleman." By so doing they are snbjected to nnjnstifiable tronble and expense. All communications should therefore be addressed *solely to The Editors of the Journal of Horticulture, &c.*, 171, *Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee snbjects, if they expect to get them answered promptly and conveniently, bnt write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

Market Gardening (*Willoughby Clark*).—We cannot advise you, or give you information. You must go and inquire at Ealing.

Shrewsbury's Heating Apparatus (*Analysis*).—You had better write to Mr. Shrewsbury, and tell him what you need. His mode of heating is good, and he knows better than we do the size you will need.

Garden Pots (*R. S.*).—We cannot recommend one tradesman in preference to another. The potters should advertise. If you refer to Kelly's Post Office Directory you will see a list of them.

Plans of Flower Borders (*Rush*).—You will find a great many plans in "Plans of Flower Gardens." It may be had post free by enclosing 5*s.* 4*d.* to our office, with your address. We cannot furnish plans, though we criticise those sent to us.

Kalosanthes after Flowering (*Idem*).—The shoots that have flowered should be cut down to within an inch or two of their base, and they will push shoots that will not flower next year. There will be other shoots that have not flowered this year, they will do so next; therefore retain them, not shortening, but neatly tying them out. In cutting back the shoots which have flowered, you must have regard to the future shape of the plant, and cut them of different lengths according as the shoots are required. Pot at the end of August, and again in April. In winter keep the plants in a greenhouse from which frost is excluded, and near the glass. We presume they are now out of doors in the full sun, as they ought to be. They should be housed before frost. The Rochea requires the same treatment, only as it has not flowered it must not be cut down, and as you wish it to flower next year the shoots must not be cut back.

Lapageria rosea Shoots Eaten (*W. R. I.*).—The lime, unless it be fresh, is of no use whatever to keep off snails or grubs. Have you looked for them after dark with a lantern? Perhaps you might take the depredators in the act, especially if you were to place a white cloth on the ground and shake the plant sharply. Grubs do not work above the ground line. It must be a weevil, beetle, or caterpillar, and a little patience and research we have no doubt will have a good result. Look on the under sides of the leaves for caterpillars. Snails and slugs may be known by their tracks.

Cutting back Clematis Jackmanni (*Idem*).—It is necessary to cut down when you wish for a greater number of shoots from the base than you have; but if you have as many as you wish, it is well not to shorten the shoots, as they will flower in the ensuing year—that is, the shoots from last year's shoots.

Fuchsia not Flowering (*Ignorance*).—We can only account for the Fuchsia not flowering from its being not near enough the glass, and, perhaps, it has but little sunshine. In a sunny window it is hard to tell how a Fuchsia can be grown without flowering. Give no more water than enough to keep the leaves from flagging, and allow a little air every day without creating too much draught. Move it as near the glass as you can.

Old Garden Neglected (*Idem*).—We presume you have only just come into possession. Being in such a bad state we should not crop it this year, but at once have it cleared of the weeds by hoeing or forking up as may be required, taking up the perennial-rooted weeds, as Couch Grass, Dock, Dandelion, Plantain, and others, with a fork, and burning them. The ground being thus cleaned and stirred you will obtain a splendid crop of weeds again by autumn, and these we would dig in before they seed. Trench the ground early in November, 2 feet deep, or, if the soil is not of that depth, as deeply as you can without bringing too much of the bad soil to the surface. If it is clayey and heavy it would be well to throw it in ridges so as to expose it to the action of frost as much as possible. During dry frosty weather in February, the ridges may be thrown down, and this will contribute much to the destruction of vermin and the amelioration of the soil. In March give a good dressing of lime, and at the end of the month you may crop the ground with Potatoes, and every kind of vegetable you require, manuring well before planting or sowing.

Maréchal Niel Rose (*C. F. O. S.*).—"It is so late in the season that I should not advise you to try and make your rampant Maréchal Niel bloom. Let it alone, and next spring take off the points of the shoots to a good eye in firm wood; and it will break, and bud, and bloom again. I have four plants in front of my house (south aspect) without a single leaf. —W. F. Radclyffe."

Plants for Conservatory Wall and Baskets (*St. Dennis*).—As you wish for evergreens, our selection is curtailed—Rhynchospermum jasminoides variegatum, Hoya carnosa variegata, Lucnlia gratissima, and Habrothamnus elegans may suit you. The former two have variegated leaves and flower in summer; the latter two flower in winter and spring; one of each has sweet-scented flowers. For the baskets, Ferns would perhaps serve you best if the house is shaded, or if there are climbers. The following are suitable—Adiantum setulosum, Platycerium alcicorne, Drynaria pustulata, Niphobolus rupestris, Nephrolepis exaltata, N. tuberosa, and Selaginella cæsia. There are few plants with variegated foliage suitable for baskets, the exceptions are—Saxifraga sarmentosa, S. Fortunei, Sedum japonicum variegatum, and S. Sieboldii variegatum. Pothos argyrea is a good basket plant but requires a stove; it has ornamental foliage, and will do in a conservatory in summer.

Centaurea for Bouquets (*W. T. C.*).—The Centaurea used for bouquets in Covent Garden Market is C. Cyanus, known commonly as the Corn-flower. As you ask for a monosyllabic answer to your other query, we say, "No."

House Sewage (*A. B., Exeter*).—If you enclose four postage stamps with your address and order "Muck for the Many," it will be sent to you free by post. This little pamphlet contains very full directions for the use of sewage and other manures.

Heating a Small Greenhouse (*Peter T.*).—A small brick stove, such as lately described, would heat your house, 18 feet long by 10 feet wide, and so would a small iron stove, which you could remove from April to October. If you wish to combine neatness with efficiency, and can go low enough for a stokehole, we would have a flow and return small flue beneath the floor, and the top of the flue would then form part of a tiled pathway. Such a flue could be formed of a single brick on edge, and a thin tile for the bottom; but for lasting effects we prefer brick on bed—say, two or three in thickness. A single flue, say 6 inches wide, would be sufficient if you took it across the ends, and up a chimney at the farther end. If you merely took it along the front, a double one 4 or 5 inches wide would do, the chimney being above the furnace. We heated a small house in this way, and we know of nothing neater and cheaper, as no flue is seen, and in a cold damp day in winter the warmed paving tiles are pleasant to walk on. The flues were just covered with thin tiles, plastered over, and on them were placed 9-inch paving tiles on the level of the floor.

Vines and Cucumbers Infested with Red Spider (*Walton Hall*).—The whole of the leaves, Vine and Cucumber, are destroyed by red spider. Nothing will set them right for this season, but you may preserve them in the state they are in, were you to heat the flues no warmer than the hand can bear, and paint them, after closing the house, with sulphur brought to the consisteucy of thin paint, by a solution of 4 ozs. of soft soap to the gallon of water. It should be applied whilst the flues are hot, and when the sulphur fumes are given off, sprinkle the flues lightly after painting them with water. The sulphur paint may be applied with a whitewash brush, and another coating should be put on after sprinkling. On the following morning a good syringing should be given. Within a week repeat the process, as yours is a bad case. Pick off the worst leaves from the Cucumbers, and treat in the same way, only syringe every morning and evening, and sprinkle the paths and other surfaces with water twice or thrice a-day. Dress the Vines in autumn as soon as the leaves fall, with 8 ozs. of soft soap to a gallon of tobacco water, made by infusing 4 ozs

tobacco in a gallon of boiling water. Cover up and allow the whole to stand until cool; then strain and add 1 lb. lime and as much sulphur vivum as will give the consistency of paint. With this mixture coat the Vines, rubbing it well into every crevice, but take care of the eyes so as not to rub them off, stripping off the loose bark previously. The application may be repeated after pruning, and the walls washed with lime and sulphur, the house being thoroughly cleaned.

VINE LEAVES SHRIVELLED (*D. H.*).—We examined the Vine leaves closely but could find no insects, though we are tolerably certain that they have thrips or red spider, and probably both. The leaves have also traces of scalding. You must examine closely for the insects, and if you find the small jumping thrips, fumigate with tobacco; if the small red spider, use sulphur on the pipes, and wash all open spaces with soft soap and sulphur. For the burning, more air and ventilation must be given, especially early in the morning.

PROPAGATING OUT-DOOR GRAPES (*J. T.*).—The Vine ought now to be summer-pruned, if not already done. This pruning consists in thinning-out the shoots, not leaving them too close together, but laying in enough to fill vacant spaces, stopping the shoots bearing fruit one joint or two beyond the bunch, neatly tying and securing them to the wall, not only to produce a neat appearance but to give every part its full share of light, air, and warmth. 1, The wood for propagating from should be removed in autumn, when the leaves have fallen. 2, Last year's wood—that produced this year being taken after the leaves fall, and vigorous well-ripened shoots. 3, Cut into lengths of 10 inches or 12 inches. It will be sufficient if the cuttings have two eyes or buds; cut across below the lower eye and slantingly above the upper one, and insert at once at the foot of your south wall, and so deeply that the upper eye may be level with the surface of the soil. The soil most suitable is a sandy loam. Cover the top of the cutting with leaf mould or very fibrous loam to the depth of 2 or 3 inches. You will have shoots from the eyes about this time next year.

SWEETWATER GRAPES CRACKING (*B. B.*).—To ripen them well and without cracking, the air of the house must be kept dry and abundance of ventilation given. The border, too, should not be allowed to become wet after the ripening commences. There does not seem to have been any neglect in the management up to the time of ripening. Keep the Vine drier both as regards the atmosphere and at the roots, and you will probably escape the disaster next year. The red spider would not cause the berries to crack.

FORMING A VINE BORDER (*R. J.*).—The border being entirely outside, you would do well to keep it as much as possible above the ground level, so as to have it dry. The depth should be from 3 feet 6 inches to 4 feet, and the bottom should be concreted, and incline to the front, where there ought to be a drain running lengthwise, and having a proper fall and outlet, so as to take away superabundant water. One foot in depth should be drainage—stones or pieces of brick, coarse at the bottom, and finer at top. The width of the border should be equal to that of the house, but a 12-feet border will answer very well. It may be made at different times. From 4 feet to 6 feet will be quite wide enough to make it at first. This width will serve the Vines three or four years, and you can add to the width at the end of the third or fourth year. The materials we advise for making the borders, are the top 3 inches of a pasture, where the soil is a good light loam, using it fresh, and cut into pieces about 6 inches square—nine single-horse cartloads; five bushels of charcoal, five bushels of bruised bones, five bushels of calcined oyster shells, five bushels of chalk in pieces not larger than a hen's egg, one load of old lime rubbish, and one load of stable droppings, as free of straw as possible. Mix all well together, and put in the border, surfacing with 6 inches of rotten sods, and put in a barrowful of bones to six of rotten sods. The border should be made 9 inches higher than the intended level, to allow for settling. The roots should be confined to the border by a brick wall. We should have liked your border better had you contrived to have the Vines planted inside. Calcareous soils are not injurious, but essential to Vine culture.

TUBEROSES (*Idem*).—The bulbs should be potted in spring as soon as received, in 6 or 7-inch pots, in rich light turfy loam, and be placed in a gentle heat until they have begun to grow, and being well hardened off should be removed to a light, airy position in the greenhouse, where they will flower in due course. They are not difficult to flower. The bulbs are not of much value in the following year. We think the name of the plant you describe is Sempervivum californicum, having thick fleshy green leaves, tipped with purple. It is of very dwarf, close habit; a fine edging plant.

ROSE SHOOTS SHORTENING (*Agnes*).—The very long vigorous shoots should be left at their full length until the pruning season, when they may be cut back as required. If you wish for dwarf plants, then for the sake of appearance they should be cut back now to the height wished for in summer. If you peg down the long shoots in autumn, merely taking off their weak unripe points, they will shoot from almost every eye, and produce numerous blooms next season, and the height will not exceed from 12 to 15 inches. The shoots which have flowered should be cut back to within six buds or eyes of their base, and you will obtain shoots for autumn flowering if the Roses are Perpetuals, or of kinds which flower in autumn.

GRAPES RIPENING *Idem*).—A little fire heat to admit of free ventilation is desirable when the Grapes are ripening, giving it more in the day than at night. The more air they have the better, if the proper temperature be secured, and air should be given at night as well as by day. One-fourth the amount that is given by day will be sufficient at night. The ventilation should be so given that the Grapes may be safe from rain, for if that fall upon them the bloom will be destroyed.

HAND BOUQUETS AT MANCHESTER (*Evergreen*).—You are wrong, no third prize was awarded so far as we are aware. We published the official list in our number for July 22nd.

BERBERRY HEDGES MILDEWED (*A Subscriber*).—The mildew attacking the Berberry is one form, and that attacking Wheat another form, of the same parasitic fungus, Æcidium berberidis. Almost every plant has its destructive parasite. You may cut the hedge as you propose, and place greenhouse plants by the side of it. They, probably, will not have the mildew of the Berberry communicated to them; but we do not say they will be free from the disease peculiar to each genus or species.

ERUGMANSIAS NOT FLOWERING (*Idem*).—The plants are probably too liberally potted, and are not kept near the glass in the full sun, with plenty of room and plenty of air. To flower them early the plants should be placed in gentle heat in February or March, after being well pruned-in. A vinery is a suitable place to start them in. Have the wood well ripened, keep them dry in winter, and do not overpot, using sandy loam moderately rich. Water well when they are growing, and keep them free of red spider by syringing forcibly.

RETARDING FLOWERING (*Bab*).—You may safely cut off all the most forward Lobella flowers so as to encourage the plants and have more bloom in three weeks. In the case of Pelargoniums and Calceolarias we would only cut off all the old fully-expanded blooms, and leave all those beginning to open. The mere blooming does not exhaust the plants much if no seeding is allowed. Still we have no doubt that the beds will be more brilliant three weeks hence, if treated now as advised above.

FLOWER BORDER (*J. S.*).—For a complete change in such a border, it would look very well with a simple arrangement like the following:—Begin at one end and make circles 3 feet in diameter, so as to leave 1 foot in the centre between circumference and circumference. Fill both sides, that foot and the wider space made by the sweep of the circle, with Cerastium tomentosum from your present edgings. This will give you plenty of white as a groundwork; then fill all your circles with Tricolor Pelargoniums, as Mrs. Pollock; and bright colours as Stella, Christine, &c. You might mix or edge Mrs. Pollock with blue Lobelia, and your pinks and scarlets with Purple King Verbena. Arrange your colours regularly. Coleus Verschaffelti would come in well. We once had such a border and liked it much. The circles we think the simplest, but you might have formed squares and circles alternately. Much will depend on the carpeting of Cerastium.

BUDDING ROSES (*Hampshire Highlander*).—The buds make the best growth when they remain dormant until the spring succeeding the budding. We do not think it desirable to force them into growth at this season by cutting back the stock, for the shoots cannot become well-ripened, and in severe seasons they perish; if not, they mostly grow weakly in the succeeding year.

CHALK BANK IN KITCHEN GARDEN (*Idem*).—The bank would no doubt answer well for Vines if you were to cover it with glass. With ground vineries you might grow Vines very successfully, the situation being admirably suited for the purpose. Cucumbers you might grow in summer with the assistance of hand-glasses. The elevation is too great to enable you to succeed without the aid of glass. The north-east cliff might be covered with Morello Cherries and the hardier kinds of Pears. If the object is merely to cover it, plant Virginian Creeper and Ivy, or Honeysuckles and Ayrshire Roses.

PLANTING CARNATIONS AND PICOTEES (*S. H. M.*).—The best time to plant is March, the plants having been wintered in a cold frame. They may also be planted in September. The best compost is two-thirds of old turfy loam, light rather than heavy, and one-third of old cow dung or well-rotted stable manure. Carnations:—Captain Stott, Lord Ranciffe, Dreadnought, Eccentric Jack, Sportsman, and King John. Picotees:—Green's Queen, Admiration, Amy Robsart, Rev. H. Matthews, Miss Wood, and Charmer.

RAIN WATER (*Idem*).—It becomes considerably altered by standing, and though the best possible water at all times for plants, is not so refreshing when taken from a tank where it has been weeks or months as when fresh from the clouds.

CUTTING BACK ARBUTUS AND LAURUSTINUS (*Colchester*).—The best time in the whole year to cut-in all the plants you name is spring, when they are beginning to grow, or a little before. As a rule, the beginning of April is a good time, and cutting-back may be performed up to the middle of May if the growth has not made much progress. Flowering will then be over, and the shrubs will make a good growth, and have time to perfect it before winter. Besides, by cutting-back in spring, the unsightly appearance of hard cutting is removed, before the summer is far advanced, by the appearance of the fresh foliage. Summer and autumn pruning ought only to be practised when they do not render the objects unsightly, as in the case of hedges or shrubs regularly trimmed.

TRANSPLANTING RASPBERRIES (*C. S.*).—They ought not to be removed until the leaves have begun to fall, and the earlier they are moved afterwards the better, giving a good mulching with half-rotten manure over the roots, a short distance from the stem.

LANTANA PROPAGATION (*R. S.*).—They are propagated from cuttings of the growing shoots, taking them off when their bases become a little firm, but not ripe, and if they have three joints and the growing point they are long enough. Cut below the lowest joint, trim off the leaves from that and the next joint, insert the cuttings up to the leaves in a compost of two-thirds sand and one-third fibrous loam, with a little leaf mould, and place in a gentle bothed of 70° to 75°, keeping them close and shaded from bright sun. They will be struck in a fortnight or three weeks. Harden them, and pot off. Throughout the summer cuttings may be put in, and now is a good time to raise plants for next year's blooming.

WISTARIA FLOWERING TWICE (*Subscriber*).—We knew of no process by which the Wistaria can be induced to flower twice. We had it in flower this year in April, and having stopped all the long shoots at the third leaf, and repeatedly to one afterwards, except those required for extension, which are of course trained in at their full length, it has now some racemes of flowers. The production of such is not uncommon. Your plant will, no doubt, flower well next year. The long shoots must be well ripened, otherwise they will not form bloom buds. Grown in 12-inch pots, and kept closely pinched-in, Wistarias make splendid plants for forcing, and are of a colour much wanted among forced plants.

AUCUBA LEAVES COVERING BERRIES (*Idem*).—Why remove the shoots? The berries will look all the better of being surmounted by handsome foliage. The leaves are no detriment to the berries. The latter will attain perfection, and be very attractive in spring.

DESTROYING MUSHROOM SPAWN IN A VINE BORDER (*W. E.*).—The Mushroom spawn would soon disappear if you were to fork the soil over and saturate it with water. The border is much too dry, and could not be made sufficiently moist without disturbing the soil, for the masses of spawn are all but impervious to water. Last winter in very wet ground we found, in trenching for park-planting, several patches of spawn as dry as dust, whilst the surrounding ground was very wet. Fourteen pounds of lime to thirty gallons of water stirred well up, allowed to stand two days, and the clear liquid applied to the border, would destroy all the

spawn it touched; but a good watering after forking over the border would have the same result. Destroy the Mushroom spawn, for fungi are destructive to vegetable fibre, and especially decayed turf.

Coal Ashes as Nonconductors of Heat (*H. W.*).—The finely-sifted ashes will do very well for the purpose of placing below the double wall of boards, provided they be kept dry. If they get damp, from the weight, they will be apt to make the boards bulge. If you could make sure of the joints of the boards being airtight, you might dispense with either ashes or sawdust between, as the hollow space would be the best of all nonconductors, but that space will only act in this way when airtight. We fear that for a rough job you might have trouble in so joisting the boards. The best mode is to groove the boards and join them with slips of plate iron, and the joints never gape. Instead of 5 inches between the boards, we would be satisfied with 2 or 3 inches. Wood is a good nonconductor.

Measurements—Shy-seeding Pelargoniums (*E. J.*).—A foot run is merely a foot in length, such as a rod, line, or string, the foot being simply 12 inches in length. A foot superficial is a square foot—that is, 144 square inches. This is generally used for measuring most surfaces, multiplying length and breadth into each other. Many sorts of work are measured by the square of 10) feet. Solid measure takes cognisance of depth as well as length and breadth; thus a solid foot will contain 1728 cubic inches, being 144 inches multiplied by 12 inches. The funnel-shape has been more or less used in conical-boilers. We have not noticed the seeding of shy-seeding Pelargoniums this year in the open air, but it may be partly owing to the peculiar season in your fine climate in the Isle of Wight.

Ferns Infested with Insects (*An Old Subscriber*).—The Scolopendrium and Asplenium fronds are infested with thrips. There is but one remedy—fumigate the house or case they are in with tobacco, when the fronds are dry. Choose a calm evening, and shut up closely, so as to retain the smoke about the plants as long as possible. The smoke should be so dense that it will be impossible to see the plants from the outside. Keep close and moist the following day, and repeat the fumigation the next night but one, and whenever an insect is seen. The plants have been kept much too dry and warm. Keep them cooler and moister. Pick off the fronds worst affected, and burn them. You will destroy in that way many insects in the egg state. Much may be done by drawing a wet sponge along the back of the fronds, or where the insects prey.

Names of Plants (*W. O., Didsbury*).—1, Adiantum capillus-Veneris; 2, Microlepia novæ-zelandiæ; 3, Adiantum hispidulum; 4, Caladium argyrites. (*A Subscriber*).—Olearia argophylla. Propagate it by cuttings in spring or summer. (*R. Maitland*).—Sterculia rupestris. (*P. T. O.*).—Both varieties of Salvia Horminum. (*J. Taylor*).—We cannot name florists' varieties such as your Begonia. What you call a Moss is Selaginella denticulata. (*K. G.*).—The tree is Salisburia adiantifolia, or Maidenhair tree. (*T.*).—Spiræa ariæfolia. (*Grangefield*).—3, Aspidium capense; 1, Asplenium furcatum. (*A. L. O. F.*).—Nos. 1 and 2 are insufficient to determine clearly; No. 1 might be Cystopteris fragilis, and 2 a Nephrodium; No. 3 is Campyloneuron lucidum; and 4, Selaginella Kraussiana (S. hortensis). (*Devon*).—Mentha gentilis variegata; 6, Mesembryanthemum violaceum. (*H. J.*).—3, Polypodium membranaceum; 4, Stapelia, corolla had been lost, calyx and pistil only remaining; 5, Erica, probably E. pedunculata; 6, Gesnera discolor. (*Devon*).—1, Rhodochiton volubile; 2, Gnaphalium antennaria; 4, Spiræa callosa, also called S. Fortunei; 5, Centaurea depressa. (*T. L.*).—Bromus racemosus. (*H. J.*).—1, Dieffenbachia segnina; 2, Microsorum iridioides. (*Guilielmus*).—Ajuga reptans alba. (*E. H. W.*).—1, Eriophorum polystachyum. (*Bournemouth*).—2, Leycesteria formosa. (*New Forest*).—1, Bignonia grandiflora; 2, Erythræa Centaurium. (*Georgiana*).—Senecio viscidus. (*A. Y.*).—Galium verum. We fear you would not be able to obtain anything of value by hybridising this plant.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending August 10th.

POULTRY, BEE, AND PIGEON CHRONICLE.

BLACK-BREASTED RED GAME FOWLS.

Under this head my friend Mr. Dear has given, at page 90, a few particulars of his doings in obtaining a subscription-cup for Black Red chickens at the approaching Show of the Hampshire Ornithological Association, to be held at Southampton on the 9th, 10th, and 11th of November.

As the breeders of Brahmas have been named, I feel I should be wanting in my duty if I omitted calling your readers' attention to the liberality displayed by various breeders of this description of fowl, who during the past three years have contributed very little short of £20 as extra prizes for Light Brahma chickens, which I need scarcely say has brought together the largest entry of this variety that has ever been previously obtained. The great promoter of this variety of our feathered host, Mr. J. Pares, was the pioneer of this annual cup, and contributed the money in a thoroughly liberal spirit, throwing the competition open—first, with a view to support the Southampton Show; secondly, to place the Light variety on a better standing than was previously the case; and thirdly, to give an opportunity to any new exhibitor who may only recently have entered within the pale of "the fancy" for this breed. Surely this is worth imitating, and I had only hoped that Game fanciers would have contributed their support on equally liberal terms.

Depend upon it if those gentlemen named by Mr. Dear wish for a large competition, they must expand their views, be more liberal in their offers; then, I have no doubt, they will meet with the success which the breeders of the Light variety of Brahmas have done. I should mention that at the large show last year the cup was taken by a gentleman who positively refused to subscribe, but he soon became a convert and handsomely contributed to the cup for 1869, and, I believe, will subscribe as long as the promoters of this cup continue their annual support. Much interest is attached to the cup for this year, the subscription for which has already reached seven guineas. Mr. Edward Hewitt, the eminent poultry judge, was one of the voluntary contributors. This example has been well followed up, and I hope in the course of the next week to learn that others have come forward with equal liberality to support the views of gentlemen who lay down *no restrictions*, but simply ask for aid, that the entry for this variety of fowl may not fall short of that of previous years. Mr. Philip Crowley, of Croydon, an ardent admirer of this variety, has undertaken to collect the requisite material this year, and the success he has met with at once shows no pains have been spared on his part to make the cup worthy of competition.

Several cups are being subscribed for by gentlemen whose wish is, that the next show should outdo its predecessors.—P. Warren, *Hon. Sec., Hampshire Ornithological Association.*

COMPOUND FOODS FOR FOWLS.

The advantages claimed for compound foods by their inventors are, as I understand them, as follow:—In the first place, by selecting the finest of those meals proved by analysis to be richest in flesh-forming and heat-giving principles, and combining them, the greatest per-centage of nutritious and stimulating properties is obtained in a condensed and easily assimilated form. Secondly, that by the use of tonics, and of stimulants which are known to exercise a beneficial effect, combined in quantities which experience and observation have determined, we may obtain a general tone of health and vigour, protection from disease and variability of temperature, rapidity of development, and perfection of plumage.

Now I do not think anyone will accuse me of interested motives when I say that after a fair, honest trial I find Dear's food most satisfactorily fulfil these conditions. I have at the present moment upwards of three hundred chickens all fed on it, and not a sickly or diseased bird among them, whilst their appearance and growth are remarkable. My method, however, of preparing the food differs somewhat from that of Mr. Loe, and I think, perhaps, on trial he will prefer it. I have tried various ways of preparing it, but the best in my opinion is as follows:—

I have a large zinc pan, and put into it one-third of barley-meal, one-third of the best fine middlings (this when good should be almost as white as flour), and one-third of Dear's food. I mix them thoroughly together, running the meal well

through the fingers, then hollow out the centre, pour in rapidly boiling water, stir all the time with a trowel, knead to the consistence of a thick crumbly paste which I press into lumps of the size of a cricket ball, and feed. I commence with my young stock about 6 A.M. I am a great stickler for cleanliness, and I take every precaution that the pan is thoroughly scalded out after each making.

In Mr. Dear's prospectus he claims that the loss of birds reared on his "Food" does not exceed five per cent. My loss this year has not been 2½ per cent., and these were mostly in January and February. My honest opinion is that Dear's food gives strength to early-hatched chickens; they grow fast on it, their heads and faces are of a rich red, and as far as condition and plumage are concerned I would wish for nothing better. I think it is a great help to birds in the moult.

I saw in your number of July 15th, an opinion expressed that the plague of feather-eating fowls now so prevalent "is principally to be attributed to artificial feeding." My opinion is that if every breeder used Dear's food prepared on the system I have mentioned, had his poultry kept clean, and gave pure water placed in the shade, not allowed to heat in the sun, we should hear much less about it.—FREDK. WRAGG, *Stoke Park, Ipswich.*

ALLERTON POULTRY SHOW.

THE fifth Show of the Allerton Agricultural Association was held on the 7th inst. The show of Poultry, Pigeons, &c., was very extensive, though the Society is comparatively young. Every year from its establishment there has been an augmentation of the prize list, and the good management of the birds while in the hands of the Committee has so gained the confidence of the exhibitors, that some of the best birds in the country are shown, many of them being sent from great distances.

In the poultry section, the single *Game* cocks were first, and the first-prize Black Red was nearly perfect; and the same may be said of the first-prize Silver-spangled *Hamburghs*. Adult *Cochins* showed to advantage, but *Spanish* did not look so well. Considering the season the *Hamburghs* were good and in fair condition, and the cup went to the most perfect pen of Golden-spangled we have seen for some time. Many of the *Game* were in bad feather, though there were several excellent pens.

In young poultry the first-prize *Spanish* were most beautiful in face and drop, and the first and second *Cochins* were also good; but, ere long, these two pens will change places, as the birds in the latter pen are the most beautiful in colour we remember, though wanting the size of the first. In *Hamburghs*, the Silver-spangled and Pencilled were very good, especially the pullets in the latter. The *Game* were not equal to those shown last year; though this remark does not apply to their numbers. The *Game Bantams* were good, and the cup was given to an excellent pen of Black Reds; but the Bantams in the "Variety class" were poor.

Some excellent Aylesbury, Rouen, and Teal *Ducks* were shown.

The *Pigeons* were a great feature of the Show, and were of special interest to the visitors. Of Ponters there were but two entries, but the Carriers were more numerous. In the Short-faced Tumblers, the first were Almonds of special quality of head and well broken in the feather. Among the Long-faced Tumblers, the first prize went to a very neat pair of Blue Balds; the second to perfect Red Mottles; and the third to Yellow Mottles, which lost only in size, being a little coarser than the rest. The first-prize Owls were White foreign, and the second Blue English. The Turbits were the strongest class of the Show, there being twenty-one entries, and though there were birds of great beauty, there was not a perfect pair in the lot. Those birds which had the most beautiful characteristics of the Turbit head, were deficient in colour, and those that were most perfect in colour were a little foul-thighed. Five prizes were awarded in this class, and were given as follows:—First, Blues; second, Reds; third, Yellows; fourth, Reds; fifth, Yellows. The Jacobins were a good class, and the prizes were all carried off by Reds. Fantails were of high quality, and the tails of immense size. Of Barbs, the first and second were capital Blacks sent from Sussex; and the third, Yellows. Of Dragoons, there were seventeen entries, and most of them were noticed. The first-prize Reds were a grand pair. Trumpeters were large, well-feathered, with excellent roses; Blacks being first; Fawn-coloured Splashes second; and Black Mottles third. It would be impossible to improve upon the prize-winners in Nuns as regards either quality or condition. That most reprehensible practice of showing two cocks as a "pair," seems to have become quite common of late, and in consequence several suspicious-looking "pairs" were passed over unnoticed in the previous classes; but in that for Antwerps, two birds were exhibited in one pen which were most certainly both male birds, and so palpable was this that it admitted of no excuse whatever. The winning Magpies were Red, Yellow, and Black, all three pens being nearly perfect in all points. Archangels were not good. This beautiful variety of Toys seems to be degenerating rapidly. In the "Variety class," Red Swallows were first, German Ice second, and Black Swallows third, all being first-class.

For *Rabbits* there were but two classes; the first prize pair of Lop-ears measured each 4½ inches in width, and one 21¼ inches and the other 21 inches in length; the second, which were not in good condition, 4¾ inches and 4½ inches in width, with 21 inches and 20¼ inches in length; the third 4½ inches and 4⅞ inches, and 20⅞ inches and 20 inches in length, but not at all matched in colour. In the "Variety class," the first were very good Chinchillas; the second a beautifully-marked pair of common Black and White; the third pure White Angora.

SINGLE COCKS.—*Game.*—Cup, 1, and 2, J. Settle, Manningham. 3, W. Fell, Adwalton. *Hamburgh.*—1, H. Beldon, Goitstock, Bingley. 2, A. Driver, Morton Banks. 3, W. Clayton, Morton Banks. *c*, H. Pickles, jun., Earby. *Bantam.*—1, W. F. Entwisle, Leeds. 2, J. Crosland, Wakefield. 3, J. Walker, Halifax.

SPANISH (Black).—1 and 2, H. Beldon. 3, J. Thresh, Bradford.

COCHIN-CHINA.—1 and 2, W. A. Taylor, Manchester. 3, C. Sedgwick, Ryddlesden Hall. *c*, H. Beldon.

HAMBURGH (Silver-pencilled).—1 and 2, H. Beldon. 3, H. Pickles, jun.

HAMBURGH (Silver-spangled).—1 and 3, H. Beldon. 2, W. A. Taylor. *c*, H. Pickles, jun.

HAMBURGH (Golden pencilled).—1 and 3, H. Beldon. 2, H. Pickles, jun.

HAMBURGH (Golden-spangled).—Cup and 1, H. Beldon. 2, H. Pickles, jun. 3, S. & R. Ashton, Mottram. *c*, J. Rollinson, Lindley.

HAMBURGH (Black).—1, C. Sedgwick. 2, W. H. Illingworth, Idle. 3, J. Smith, Gilstead. *c*, H. Beldon.

POLAND.—1 and 2, H. Beldon.

DORKING.—1, J. Stott, Healey, Rochdale. 2, J. Walker, Knaresborough. 3, Hon. H. W. Fitzwilliam, Wentworth Woodhouse.

GAME (Red).—1, E. Aykroyd, Bradford. 2, H. Jowett, Idle; R. Hemingway, Shelf.

GAME (Any other variety).—1, G. Noble, Staincliffe, Batley. 2, W. Fell; H. Jowett. *c*, J. Sunderland, Coley Hall, Halifax.

SINGLE GAME HENS.—1, H. Beanland, Bradford. 2, E. Aykroyd. 3, T. Bottomley, Shelf, Halifax. *c*, J. Smith, Allerton.

GAME BANTAM.—1, W. F. Entwisle. 2, J. Crosland, Wakefield. 3, Miss K. Charlton, Bradford.

BANTAM (Any other variety).—1, H. Beldon. 2, W. Brotherton, Idle. 3, H. Pickles. *c*, S. H. Stott, Rochdale.

ANY VARIETY NOT PREVIOUSLY MENTIONED.—1, E. Leech, Rochdale. 2, R. Loft, Woodmansey, Beverley. 3, Hon. H. W. Fitzwilliam, *c*, C. Layland, Morris Brook.

CHICKENS.

SPANISH (Black).—1, H. Beldon. 2, W. & F. Pickard, Thorner, Leeds. 3, J. Berry, Silsden.

COCHIN-CHINA.—1 and 2, C. Sedgwick. 3 and *c*, W. A. Taylor.

HAMBURGH (Silver-pencilled).—1 and *c*, J. Walker, Knaresborough. 2, H. Beldon. 3, H. Pickles, jun.

HAMBURGH (Silver-spangled).—1, H. Beldon. 2, Ashton & Booth, Mottram. 3 and *c*, W. Bairstow.

HAMBURGH (Golden-pencilled).—1, H. Beldon. 2, J. Sugden, Thornton. 3, G. J. Taylor, Huddersfield. *c*, J. Walker.

HAMBURGH (Golden-spangled).—1, T. Walker, Denton. 2, W. Driver, Keighley. 3, J. Murgatroyd, Idle.

HAMBURGH (Black).—1, C. Sedgwick. 2, J. Cockroft, Hawkcliffe. 3, T. Hanson, Thwaites Bank. *c*, C. Sedgwick; E. Baxter, Idle.

POLAND.—1 and 3, H. Beldon. 2, J. Bowker, Keighley.

DORKING.—1, J. Walker. 2, T. Briden, Earby. 3, J. Stott, Healey.

GAME (Red).—1, H. Jowett. 2, J. Pearson, Allerton. 3, W. Johnson, Idle

GAME.—*Cockerel.*—1, H. Jowett. 2, H. Hatton, Cleckheaton. 3, T. Dyson, Halifax. *Pullet.*—1 and 3, J. Carlisle, Earby, Skipton. 2, J. Hird, Bingley. *c*, W. Johnson, Idle; J. W. Thompson, Southowram.

GAME (Any other variety).—1, L. Wimwood, Worcester. 2, J. W. Thompson. 3, J. Fell, Adwalton.

GAME BANTAMS.—1 and Cup, W. F. Entwisle, Leeds. 2, J. Crosland, Wakefield. 3, G. Noble, Staincliffe.

BANTAMS (Any other variety).—1, W. A. Taylor. 2, H. Beldon. 3, S. Shackleton, Keighley.

SELLING CLASS.—1, J. Smith, Allerton. 2, J. Bowker, Keighley. 3, H. Beldon.

DUCKS.—*Rouen.*—1, E. Leech, Rochdale. 2, W. Bentley, Allerton. 3, S. H. Stott, Rochdale. *Any other Variety.*—1, E. Leech. 2, A. & J. Trickeld, Waterfoot. 3, W. Greaves, Bradford. *Ducklings* (Any variety).—1, E. Leech. 2, C. Sedgwick. 3, J. Wilson, Farnhill.

PIGEONS.

A Silver Cup, value three Guineas, as an extra prize, given by Mr. Beldon, to the exhibitor who received the most value in prizes.—E. Horner, Harewood.

POUTERS OR CROPPERS.—1 and 2, E. Horner, Harewood.

CARRIERS.—1, J. Hawley, Bingley. 2, E. Horner. 3, A. Smith, Skipton. *hc*, J. Thompson, Bingley.

TUMBLERS (Short-faced). — 1, J. Fielding, Rochdale. 2, 3, and *hc*, J. Hawley.

TUMBLERS (Any other variety).—1, W. Lund, Shipley. 2 and *c*, J. Hawley. 3, E. Horner. *hc*, W. Lund; W. Shelton; J. Hawley.

OWLS.—1, J. Fielding. 2, T. Eggleston, Halifax. 3, J. Hawley.

TURBITS.—1, R. Wilson, Thirsk. 2, W. Green, Keighley. 3, J. Hawley. 4, E. Horner. 5, J. T. Lishman, Girlington. *hc*, J. Holden, Wibsey; W. Lund, Shipley; H. Yardley, Birmingham; J. Booth, Allerton; R. Wilson. *c*, J. T. Lishman; E. Horner.

JACOBINS.—1, J. Thompson. 2, J. Hawley. 3, E. Horner. *hc*, J. Hawley; E. Horner. *c*, J. Thompson; J. T. Lishman; T. Eggleston.

FANTAILS.—1, J. T. Lishman. 2 and *hc*, J. Hawley. 3, E. Horner. *c*, S. A. Willie, Surrey.

BARBS.—1 and 2, J. H. Ivimy, Grinstead, Sussex. 3, J. Fielding, jun. *hc*, J. Fielding, jun.; J. Hawley; E. Horner. *c*, H. Yardley; E. Horner.

DRAGOONS.—1, J. Thompson. 2, H. Yardley. 3, J. Hawley. *hc*, J. Greenwood, Queensbury; H. Yardley; A. Smith, Skipton; E. Horner; T. Forrest, Bradford. *c*, J. Candale, Ripon; J. Thompson; R. Wilson, Thirsk; H. Hanson, Manningham.

TRUMPETERS.—1, E. Horner. 2 and 3, J. Hawley. *hc*, J. Candale; J. Thompson; J. Hawley; E. Horner.

NUNS.—1 and 2, W. Croft, Killing Hall, Ripon. 3, J. T. Lishman. *hc*, E. Horner.

ANTWERPS.—1, J. T. Lishman. 2, E. Horner. 3, W. Lund, Shipley. *hc*, W. Lund; J. Hawley.
MAGPIES.—1, J. T. Lishman. 2, E. Horner. 3, M. Wood. *hc*, J. Hawley; E. Horner. *c*, J. T. Lishman.
ARCHANGELS.—1, H. Yardley. 2, J. Booth. 3, S. Smith. *hc*, S. & R. Ashton; H. Yardley; J. Booth; R. Wilson.
ANY OTHER VARIETY.—1, E. Horner. 2, S. A. Wyllie. 3, J. T. Lishman. *hc*, H. Yardley; E. Horner.

RABBITS.—*Long-eared*—1, C. Gravel, jun., Doncaster. 2, A. H. Easten, Hull. 3, A. Crossley, Halifax. *hc*, R. Leonard, Bradford; J. T. Redman, Bingley; Master T. H. Gresham, Bradford. *Any other Variety.*—1, J. R. Jessop, Hull. 2, A. Preston. 3, T. Mitchell. *hc*, Miss Beldon; J. R. Jessop, Hull. *c*, A. H. Easten; C. Gravel.

JUDGES.—*Poultry:* Mr. James Dixon, North Park, Clayton, near Bradford; Mr. Richard Teebay, Fulwood, Preston. *Pigeons* and *Rabbits:* Mr. E. Hutton, Pudsey.

MORLEY POULTRY SHOW.

THIS was held on the 6th inst. in conjunction with that of the Morley Agricultural Society. For several years this Society has had to contend with unfavourable weather on its show day; but for once it was fine. Owing to another exhibition being held in the neighbourhood about the same time, and many supposing the Morley Show to be of two days' duration, the entries were not so numerous as might have been expected, but it is to be hoped that for the future the date will be so arranged as not to clash with other shows. Every attention was bestowed on the poultry, and the exhibitors were dealt with in a considerate manner.

Spanish were a little out of feather, but the *Cochins* were much better, and the cup for that section was awarded in the latter class. The *Brahmas* were also well shown. Of *Game* there were twenty-four entries, and the cup was awarded to Brown Reds. There was also one excellent pen of Red Piles, and a neat Brown Red hen in the single hen class. The *Hamburghs* were mostly good, but the most noteworthy was a pen of Golden-spangled, to which the cup was given. The winning *Bantams* only were of note, and these were very good.

Of aquatic birds, the *Geese* were large, and the Rouen and Aylesbury *Ducks* almost perfect. The cup was awarded to the Rouens.

The *Pigeons* were good throughout, and in high condition and feather.

SPANISH.—1 and *hc*, H. Beldon, Goitstock. 2, J. Gornall, Little Horton. *c*, G. H. Walker, Slaithwaite.
DORKINGS.—1, J. White, Warlaby. 2, H. Beldon.
COCHIN-CHINA.—1 and Cup, W. A. Taylor, Manchester. 2, J. White, Whitley, Netherton, Wakefield. *vhc* and *hc*, C. Sidgwick, Keighley.
BRAHMA POOTRA.—1, E. Leech, Rochdale. 2, C. Layland, Morris Brook, Warrington.
GAME (Black-breasted Reds).—1, J. Fell, Adwalton. 2, G. Noble, Staincliffe, Batley. (Brown-breasted or other Reds).—1, E. Ackroyd, Bradford. 2, H. Jowett, Idle. (Duckwings or other Greys and Blues).—1, H. Jowett. 2, J. Fell. *hc*, G. Noble. *c*, A. Haigh, Morley. (Any other variety).—1, H. C. & W. J. Mason, Drighlington. 2, R. Turner (Piles). *Cock* (Any variety).—1, H. Jowett. 2, H. Beanland, Bradford. 3, W. Fell. 4, H. C. and W. J. Mason, Drighlington. *Hen* (Any variety).—1 and *hc*, H. Beanland. 2, A. Haigh, Morley. *vhc*, H. C. & W. J. Mason. *c*, E. Ackroyd.
HAMBURGHS (Golden-spangled).—1 and Cup, H. Beldon. 2, S. & R. Ashton, Mottram. *hc*, J. Rollinson, Lindley, near Otley. *c*, J. Pickles, Slaithwaite. (Silver-spangled).—1, H. Beldon. 2, W. Bairstow, Fearncliff, Bingley. *hc*, H. Beldon; W. Bairstow; Ashton & Booth, Mottram. (Golden-pencilled).—1, S. Smith, Northowram. 2 and *hc*, H. Beldon. *c*, E. Moore, Cottingley. (Silver-pencilled).—1 and 2, H. Beldon. (Black).—1, C. Sidgwick. 2, H. Beldon.
ANY BREED NOT PREVIOUSLY MENTIONED.—1, H. Beldon (Polands). 2, J. S. Senior, Dewsbury (Polands). *c*, T. Spurr, King's Lynn.
BANTAMS.—1, G. Noble. 2 and *hc*, D. Render. (Black).—1, T. C. Harrison, Hull. 2, S. & R. Ashton. *hc*, H. Beldon. (Any other variety).—1, T. C. Harrison. 2 S. & R. Ashton.
SELLING CLASS.—1, H. Jowitt. 2, H. Beldon.
GEESE (Any variety).—1, S. H. Stott. 2, J. White, Whitley, Netherton.
DUCKS.—*Rouen.*—1 and Cup, E. Leech. 2, S. H. Stott. *hc*, J. White. *Aylesbury.*—1 and 2, E. Leech. *hc*, S. H. Stott. *Any other Variety.*—1, W. Greaves, Bradford. 2 and *hc*, T. C. Harrison. *c*, S. & R. Ashton (Teal Ducks).
PIGEONS.—*Carriers.*—1, J. Hawley, Bingley. 2 and *hc*, E. Borner, Harewood. *c*, H. Yardley, Birmingham. *Owls.*—1, J. Hawley. 2, T. Eggleston. *Turbits.*—1 and *hc*, E. Horner. 2, H. Yardley. *Barbs.*—1, J. Hawley. 2 and *hc*, E. Horner. *Tumblers.*—1, J. Hawley. 2, H. Yardley. *Fantails.*—1, J. Hawley. 2, E. Horner. *hc*, H. Yardley. *Pouters.*—1 and 2, E. Horner. *Nuns.*—1, H. Yardley. *Jacobins.*—1, E. Horner. 2, J. Hawley. *hc*, T. Eggleston; R. Fleming, Hull; E. Horner. *Trumpeters.*—1 and *hc*, E. Horner. 2, J. Hawley. *Any other Variety.*—1, E. Horner. 2, S. & R. Ashton. *hc*, J. Hawley.

The Judges were Mr. E. Hutton, Pudsey, and Mr. Henry Mitchel Hipperholme.

CASTLE EDEN POULTRY SHOW.

THIS was held at West Hartlepool on the 3rd inst. Of *Spanish* the first-prize pen was excellent; *Dorkings*, *Cochins*, *Brahmas*, and *Hamburghs* were also good.

SPANISH.—1, S. Lee, Northallerton. 2, T. E. Pyman, Hartlepool.
DORKINGS.—1, R. Hawkins, Seaham. *Chickens.*—1, Miss Procter, Throsten. 2, Mrs. Burden, Castle Eden.
COCHINS.—1 and 2, G. H. Procter, Durham. *Chickens.*—1 and 2, G. H. Procter.
BRAHMA.—1, J. W. Wilton, Ryhope. 2, R. Moore, Hetton-le-Hole.
HAMBURGHS (Silver).—1, W. Whitfield, Spennymoor. 2, J. Wilson, Spennymoor. *Chickens.*—1, W. Hall, Morpeth. 2, W. Whitfield, Hetton (Golden-pencilled).—1, J. Wilson, Spennymoor. 2, F. Elston, Schofield, Morpeth. *Chickens.*—1, J. Webster, Whitby. 2, W. Hall, Morpeth. (Golden-spangled).—2, W. Whitfield. *Chickens.*—1, R. Moore. 2, W. Whitfield. (Silver-spangled).—1, W. Severs, Bedale. 2, R. Moore. *Chickens.*—1, D. Cheyne, Cowpen Lane. 2, C. Armstrong, Bibside.
GAME (Any variety).—1, J. Grainger, Castle Eden. 2, J. Wilson. *Chickens.*—1, J. Wilson.
GAME BANTAMS.—1 and 2, J. Wilson. *Chickens.*—1, J. Wilson.
DUCKS (Rouen).—1, R. Hawkins. *Ducklings.*—1, R. Hawkins. (Aylesbury).—1, R. Moore. *Ducklings.*—1, W. J. Wilton.
ANY VARIETY.—1, Mrs. Burdon (Houdans). 2 W. J. Wilton.

RED MITES ON CANARIES.

[MR. BLAKSTON has obliged us with the following, in reply to the queries of "C. A. J.," "E. B.," and other correspondents.]

I HAVE been wondering much that an earlier date than August 6th has not brought complaints of the annoyance caused by the presence of the red mite or bug, or by whatever name the parasite infesting Canaries, their cages and nest boxes, may be called. I know well that silence on the matter implies, in the great majority of instances, ignorance of their presence, just as I have known a gardener congratulate himself early in the spring on his currants being free from caterpillars, while his neighbour wisely spent an hour morning and night in hunting for them, when so tiny as to be scarcely visible, yet still quite large enough to play havoc with the opening buds. The result in the one case was a crop of fruit, in the other a visitation as dire as a plague of locusts. I could mention many an instance where the not-unusual query among Canary breeders, "Much troubled with vermin this year?" has met with the response, "Vermin! I haven't any; not such a thing in my place." And so things go on. Apparently there are none, till some day after a little extra bustle attendant upon some necessary attention to a cage, the man who "hasn't such a thing in his place," feels something tickling the back of his hand, ditto underneath his shirt collar, notices two or three little gentlemen in red livery taking their walks abroad on his shirt sleeve, and a colony of emigrants with a settling turn of mind already taking possession of the gathers and folds, with the evident intention of squatting there; and then he arrives at the conclusion that he has some of these pests of the Canary room, and begins a search. He moves a cage a little way from the wall, and stands aghast! The place is alive with them. He gently lifts a second cage from off the top of another, and finds that at every point of contact there is a fine, healthy, thriving settlement, numbering its thousands; begins to think of instituting a thorough examination, and finds every crack and crevice tenanted, the joints of the very seed boxes all occupied, the top and bottom of the cage doors, where they fit tolerably closely, all covered, and even the little wire holes in the front cross-bar, where they are not filled up to their entire depth with the wire, closely packed with the little rascals like bats in a hollow tree. An inspection of the nest boxes reveals a state of things perfectly alarming, and the wonder is how the young birds have survived the attacks of the countless legions of thirsty vampires whose aggregate bulk almost equals their own. This is no exaggerated statement. The delay of a day or two in changing a nest will often demonstrate forcibly the extraordinary fecundity of these little parasites.

In my opinion plenty of fresh air and extreme cleanliness are the best preventives. The mites do not appear very early in the season, and I think that the experience of most breeders will endorse the fact that they come in with the hot weather. I must confess that I have not studied very thoroughly the natural history of this "Cimex canariensis." I am more apt to crush a few against the back of a cage, or to throw an infested nest into boiling water, than to examine very critically into all the *pros* and *cons* of their existence, or to solve the question asked about the flies, "Where they all come from, and where they all go to?" But I lean to the theory that they require an unduly heated state of the bird's body and the surrounding atmosphere to develope them, and that by keeping these conditions in check by cooling diet, free use of the bath, and plenty of ventilation, supplemented by careful search for them, anything like annoyance from them can easily be prevented. The first place where they show themselves is in the nest, underneath the material next the box, whether it be of tin, wood, or earthenware, of which more by-and-by. They

seem to travel through or over every kind of lining material whatever, till they come to some resisting substance, when they stop and rapidly accumulate. To prevent this congregating in the nest in such disagreeable proximity to the sitting hen and young birds, many contrivances have been adopted, all of more or less merit, such as tin nests with only two narrow strips placed crosswise for a bottom, or a nest of perforated zinc, or, better still, of woven wirework, which, however, should be sufficiently open to prevent the hen being caught by her claw, in which case she is very likely to injure herself in her endeavours to set herself free. But the most effective contrivance I have seen, and one which I am assured answers its purpose well, is to use nest boxes of earthenware. We can procure a very elegant article of the kind at any of our potteries, made either glazed or otherwise. This is lined with a thick felt, which can be had of any respectable saddler and harness-maker, and is used by them, I believe, in lining saddles. There are two kinds—one white, and the other brown or black. The former is of the softer quality, and costs about 2*s.* a-pound. I prefer the latter, which is somewhat cheaper, is harder, and not so easily pulled to pieces, while the bird soon works it up to a soft surface with her feet. It is too thick to be used entire, but can be pulled into two pieces without difficulty. The secret lies in lining the nest box, which is done by mixing a little plaster of Paris to the consistency of cream in the earthenware box, and then pressing the felt into it. By this means it becomes so intimately connected with the sides of the box, that any lodgement on the part of the insects is impossible, unless it be immediately round the edges, which can be prevented by a little extra care in putting in the felt.

This method has been adopted by one of the most successful breeders in the north, and, he assures me, with complete success. The vermin must then be looked for elsewhere, and will usually be seen at the back of the nest, or between the ends of the perches and the back of the cage, from which places they can very easily be dislodged, and their rapid increase be materially, if not altogether checked. Oil, sulphur, and the thousand-and-one recipes prescribed for their extermination are very well at certain stages, but with these insects, as with other nuisances, "prevention is better than cure." I could fill this week's Journal with certain preventives, among which is mint. Said a friend to me, "I've found it!" "What?" And then came a subdued whisper, "Mint!" Next time we met I asked him, "How about the mint?" All he said was, "They fatten on it!" The best, however, is too good to be omitted, if you have another inch of space to spare. A breeder, who speaks the true vernacular of this district, says, "I've getten a trap for them; there's nout like a trap. They're larned little jockeys is them rid spiders. I put one of our Billy's buiks, a Latin buik, a top of one of my cages, and next mornin it was swa-armin! The cliver little jockeys had all getten intiv our Billy's Latin buik to larn Latin, and when I put my foot on't, and gi'ed them a bit squeeze, man, believe me I squeezed out above a gill of blood!"—W. A. Blakston.

REMOVING BEES IN HOT WEATHER.

A short time since, thinking the honey harvest in my neighbourhood at an end, I removed four strong hybrid Ligurian Woodbury hives, each having a super partly filled, to the heather. Before doing so I lifted the adapting boards and the covers of the supers, breaking the sealing of the bees to admit air. Tobacco smoke was used to drive into their hives the disturbed bees which crowded the entrances, and the openings were then closed with perforated zinc. Thus prepared they were taken in a spring cart a distance of fourteen miles to the heath, slowly during the night. The last three miles of the road were very rough indeed. My gardener on his return reported that he feared all the hives had been suffocated, but the very wet morning had prevented his opening any before leaving the stand. Returning the first fine day he found the best hive quite dead; two others, each with very few bees living, had formed royal cells; the fourth equally weak, and forming no royal cells. In each case more than three-fourths of the combs had fallen out from the frames. Having fastened these, he left them to their fate with little hope.

I have since visited the stand and find a great improvement. Young queens have been hatched in two hives, and in the third the old queen is alive and doing well. Many combs, however, are full of sealed brood with sunken covers, very dark, and having much the appearance of foul brood when opened. The cells contain either dead bees or decaying grubs, which present a dark, watery, and very unpleasant appearance. I venture to ask if, under the circumstances, foul brood is likely to occur. If not, will the bees remove the dead brood of which I have spoken? And how are strong supered hives at this season best prepared for removal and taken long distances by road to the moors?—B.

[When stocks are so strong and crowded with bees as yours appear to have been, the risk of removal during warm weather is very great indeed. You should have taken off the supers, and tacked down on every hive a square of perforated zinc in place of the top board, deepening it at the same time by the insertion of an empty hive (from which the frames and crown and floor boards had been removed), between it and the floor board. If prepared in this way, and with proper fastenings to prevent shifting, all would probably have reached the moors in safety. We do not fancy that foul brood will ensue, but it seems almost a doubtful case; and we should, therefore, advise you to send one of the combs containing dead brood to Mr. Woodbury, Mount Radford, Exeter, for his opinion.]

FOUL BROOD AND THE THEORIES OF PREUSS AND LAMBRECHT.

The Lambrecht theory appears to meet with but little favour in Germany. In the last number of the "Bee Journal" Herr Klein, of Tambuchshof, denounces it as utterly delusive, in which opinion he is confirmed by Dzierzon, the Baron von Berlepsch, and Günther.

On the other hand, the Baroness von Berlepsch, in a private letter just received, specially directs my attention to an "important article" in the same paper, from Dr. Preuss, supporting and developing his mycological theory, and begs that I will translate it into English. Unfortunately the learned doctor's article is somewhat lengthy; but as the Baroness states that both her husband and Dzierzon "stand to his colours," I will endeavour to get it turned into English, and hope to be able to submit it to the readers of "our Journal."—A Devonshire Bee-keeper.

OUR LETTER BOX.

Parasites on Fowls (*F. J. W.*).—Continue the oil, and if it fail put some camphor ointment at the back of the head, on the backbone, and under the wings. It is a certain cure. Your chickens must have suffered much before they became in the state you mention. A recurrence may be prevented by supplying them with plenty of road grit or wood ashes, mixed with one-quarter of black sulphur. They dust in this, and it prevents parasites.

Canaries Plucking Each Other (*E. S. Polkinghorne*).—Young Canaries frequently do this. There is no cure except caging separately, then the feathers will speedily grow again.

Tumbler Pigeons (*Idem*).—Let out your Tumblers fasting on a fine morning. Shout at them, and wave a flag tied to a long stick. If too fat they will not care to fly; indeed naturally Tumblers only seem to wish to fly occasionally, in certain states of the atmosphere, when rooks and other birds like to dash about on the wing. No Tumblers tumble until they are adult birds. Do not take them away from home, as you may lose them. We have had birds of our own that after six weeks' confinement flew very high and kept up a long time. All Tumblers do not tumble. Those with feathers on their legs invariably do, but then they are the worst-shaped birds. The coarser bred the better they tumble; the more beautiful the shape the less likely are they, but we have exceptions among the latter. Black Balds usually tumble well.

Hives with Combs (*C. G.*).—It is a very great assistance to a swarm of bees to be placed in a hive either wholly or partially filled with combs, provided always that the former tenants have died of starvation, not of disease.

Moths in a Hive (*W. P. P.*).—If the hive be a moveable-comb one, the combs can readily be lifted out and the moth larvæ destroyed. If the combs be fixed, we see nothing for it but to expel the bees by driving, unite them to the next stock, destroy the moths and their larvæ, and appropriate the remaining contents of the hive.

Silkworms.—"A Seamstress" wishes to know where she could dispose of the silk produced by her silkworms, and whether the skeins of silk need be of any particular size?

Maltese Dog (*J. D.*).—You have no remedy; or rather, the cost of recovering the 50*s.* would be more than that amount. We cannot understand how anyone can buy an animal they never saw.

Goat Management (*Harrard*).—We know of no book upon the subject. The following was communicated to this Journal some years since:—"Feed them as you would a cow or sheep; milk them at regular times, and strip them dry. They will eat almost any kind of food. Mine was a common Irish Goat, cost 21*s.*, and gave three pints of milk at a meal. Tie them up while milking, and milk from behind the leg. They are subject to lice: a little oil rubbed on the back is all that is required to remove the vermin. We believe one obstacle in the way of Goat-keeping is the need of keeping a buck Goat as well as milch Goats. If several persons kept Goats in one vicinity, the fragrant gentleman in question might be joint-stock."

Colouring Wine.—"Winepress" wishes to be told how much cochineal he must use to colour ten gallons of gooseberry wine, so as to give it the rosy tint of champagne.

WEEKLY CALENDAR.

Day of Month	Day of Week.	AUGUST 19–25, 1869.	Average Temperature near London. Day.	Night.	Mean.	Rain in last 42 years.	Sun Rises.	Sun Sets.	Moon Rises.	Moon Sets.	Moon's Age.	Clock before Sun.	Day of Year.

25	W	Burton-on-Trent Horticultural Show.	74.2	49.9	62.0	16	2 5	1 7	36 8	7 8	18	1 51	237

From observations taken near London during the last forty-two years, the average day temperature of the week is 72.6°; and its night temperature 49.2°. The greatest heat was 89°, on the 25th, 1859; and the lowest cold 32°, on the 21st, 1850. The greatest fall of rain was 0.95 inch.

POTATO FAILURE—PRODUCE IN CORNWALL.

SEVERAL correspondents have written in the Journal upon the Potato failure of this season, and however they may have differed upon the speculative question of the causes, they are unanimous as to the character of it. To add to the facts already recorded on this point, it may be of service to your readers to know that throughout the western part of the county of Cornwall the same irregularity of growth has occurred.

This, however, was not the case with the early crop, that planted all along the southern skirting of the county, the Mount's Bay district more particularly, in January, and which in April commences to find its way to the London and other markets, where costly rarities have an outlet; but it was found in the second crop—that planted about the second or third week in March. This year, owing to the unusually severe frost which visited us about the 14th of March, nearly the whole of what looked one of the most promising early crops ever grown in the west was destroyed. One grower alone computed his loss to be nearly £2000. The second crop was put in shortly after this frost, its usual time being about the third week in March.

In my own experience (having experimented on an acre of ground), in the first week in January I planted Rivers's Royal Ashleaf, Myatt's Prolific, Johnson's Kidney, Devonshire Kidney, Flukes, and two sorts of Kidneys of local celebrity as early sorts; these all flourished to perfection until cut down by the frost referred to. I found numbers of tubers had formed from 1 to 1½ inch long. The second crop was of the same kind, taken from the same stock of selected tubers which had been sprouted with all the precautions recommended by careful growers, saved the same time, and throughout shared precisely the same treatment as the sets of the first crop; nevertheless, whilst the first crop had no break in it and grew luxuriantly, the second had many and long gaps in the rows, and the haulms that showed themselves were stubborn, ungenerous-looking fellows, totally unlike their fraternity of the first planting. Nothing could exceed the vigour of the shoots at the time of planting; the conditions of aspect and soil were the same, both were planted in ground sloping to the south and naturally of a dry character.

Observation and inquiry lead me to regard the opinion of "J. W., *Lincoln*" (see page 40, July 15th), where he attributes the failure to over-ripeness of the seed, as the one most in keeping with the facts. The condition of the tubers, owing to the exceptional heat and sunshine of last year, was such as to require these being planted two or three months before they were. Those treated with early planting did well; those kept later failed. A certain amount of exhaustion must have taken place prejudicial to the plant, after a certain stage in the keeping of the tubers, or I do not see why, throughout so large an area of Potato-growing country as about one-half of the county of Cornwall, we could witness the facts I have stated.

Thinking it might possibly interest some of your readers to have some idea of the quantity of early Potatoes sent to London and the north during the season, from the Scilly Isles and West Cornwall, I give the figures as kindly furnished me by the Superintendent of the Cornwall Railway—to the end of June 39,064 baskets, containing 1783 tons. Of this the Scilly Isles contributed, owing to the unfavourable season, only about 20 tons of early crop. The first consignment left on the 17th of April. This quantity is much below ordinary years. There also passed over the line during the past Broccoli season 25,075 baskets, containing 2357 tons.

With your permission I may again return to the matter of Potatoes, as several new kinds have been put on their trial in this district—Patterson's Seedling, some American sorts, &c.—and when I can ascertain the results of the tests, you are welcome to the information.—Cornubia.

WAYSIDE JOTTINGS.—No. 1.

I have been induced to forward the following notes, copied almost verbatim from my diary of rambles, principally botanical, undertaken in the few leisure hours that I can spare from professional duties, in the hope that they may prove interesting to such of the readers of The Journal of Horticulture as are imbued with a love of natural history. I would not be understood to put forward any claim to be looked up to as an authority on botanical matters, but rather as a learner, who would submit his exercises for correction and improvement by other correspondents of your Journal who have greater experience. Living, as I do, at the north-western extremity of England, and acquainted only with the plants commonly found in the Cumberland valleys, I should feel obliged by a friendly comparison of notes with gentlemen from other quarters of the kingdom. Interesting as your weekly notices of flowers and flower gardens are, I think there is room for original remarks on their humbler congeners of the mountain bog or the meadow, and such notices, with all diffidence, I propose from time to time to place at your service, to print or burn them according to your estimate of their merits.

Having heard from a friend of botanical proclivities that an excellent field of observation presented itself at Dubmill, on the shore of the Solway Frith, I determined a few weeks ago to make an examination of the neighbourhood. A walk of something over six miles brought me to the place. An old-fashioned little mill, with a farm of average extent for this part of the world, stands close to the shore, divided from the shingle only by the road leading from Maryport towards Silloth. A mossy brook which turns the mill discharges itself into the Solway just below. About a quarter of a mile inland I found an uninclosed piece of moorland studded over with large ponds of water deeply tinged with the colour of the surrounding peat moss. Open cuts, serving the double purpose of landmarks or boundaries of property and outlets of the superfluous water in rainy seasons, stretched across the moor in different directions. The water in some of these "soughs,"

as the cuts are locally styled, was sluggish or stagnant, and here I found a number of interesting plants, such as do not occur except in similar localities. In the open cut nearest to the farm the most conspicuous feature was an abundance of Hippuris vulgaris, Mare's-tail, the first I had ever met with in the county, but which I knew from report was to be found there. Stooping, or rather kneeling, down by the side of the cut to secure a specimen or two for a neighbour's herbarium, I was startled by flushing a young coot, which had sought refuge under the bank, and now, in great alarm, half fluttering half diving through the water, sought shelter under the roots of the overhanging Heath on the other side. On drawing a plant or two of Hippuris from the water, I found long sprays of another curious vegetable product adhering to them, which I had not noticed, and which I might otherwise have overlooked. This was the long trailing stem of Utricularia, or Bladder-wort, with its finely-divided leaves and bright shining vesicles, from which it derives its English name, and which serve a curious purpose in the economy of the plant. In the same cut I noted a few specimens of Nuphar lutea, Yellow Water Lily, and the broad-leaved Pondweed, Potamogeton natans.

Diverging from the moor, I crossed the road on the south side, and entered the meadows through which the brook before referred to pursues its devious course. Open cuts traverse these meadows, all emptying into the brook. In some of these vegetation is abundant. Several varieties of Equisetum are found, the branching Bur Reed almost chokes the waterway, the bright yellow flowers of Ranunculus lingua are here and there very conspicuous, and the Water Speedwell, Veronica Anagallis, grows to a large size. In the brook I found four sorts of pondweed, Myriophyllum spicatum, in abundance. Water Lilies spot the surface of the stream, and one, if not two, varieties of Chara may be seen submerged in the water.

Having spent the couple of hours at my disposal in a most pleasant fashion, I turned my face homewards, mentally resolving to make a more minute survey of this interesting locality at some future and not distant opportunity.—H.

DOUBLE GRAFTING.

Mr. Grieve (see page 120) will, I am sure, excuse me for putting him right in one or two matters; I do it in a kindly spirit. Mr. Grieve states that "the system has been recommended by a French pomological writer as early as the year 1700." He has taken this idea from some inexperienced author, who should have known that it was practised in England from 1630 by Evelyn and by Rea, and that it was known by the Romans some 2000, and by the Chinese perhaps 10,000, years ago; it is also very probable that the race now buried under those tumuli which spread over such an enormous space in Eastern Tartary practised double grafting; so that it has probably been known from "a very remote period." It is, indeed, a sort of instinct in those who love gardening, to regraft a grafted tree which does not suit its place, for I recollect that when I was quite a lad I transformed a grafted Pear tree, which bore only a few sour Pears, into a fruitful tree, by regrafting it with Williams's Bon Chrêtien.

The invention of systematic double grafting is of comparatively recent date, and originated in England some twenty years since by Mr. Rivers double grafting that grand but shy-bearing Pear, Gansel's Bergamot, on trees of Beurré d'Amanlis. As many of your readers may still be ignorant of this simple way of ameliorating fruit, I will try and make it plain. First take your Quince stock (it should be the Angers Quince, and not the Paris Quince), and plant it in your garden. Allow it to grow two years, and then in August of the second year bud it with the Beurré d'Amanlis Pear. The bud will the following summer make a healthy shoot, which may be budded the first year if its growth is vigorous, or allowed to grow two years, and then be grafted in spring. The latter is, perhaps, the better mode if vigorous trees are wished for. It will thus be apparent that from four to five years are required to form a good double-grafted Pear tree.

Mr. Rivers, in his "Miniature Fruit Garden," was the first to systematise double grafting of Pears—*i. e.*, to double graft them with an end. For this reason he selected the Beurré d'Amanlis for the intermediate stock, and knowing well that the Jargonelle Pear on the Pear stock made long vigorous shoots, which after a year or two cankered and bore but little fruit, he double grafted it on the Beurré d'Amanlis Pear to make it more dwarf and fertile. It has answered admirably, and many thousands are now manufactured annually. His next successful essays were to double graft Gansel's Bergamot, to make it prolific, and take off the grittiness peculiar to that, in flavour, the finest of all Pears, and the Beurré Rance to increase its size and soften its astringent flavour. Both these objects have been attained without any great flourish of trumpets, which would have been the case had the method been gleaned from French gardens.

Mr. Rivers has also discovered a most valuable intermediate stock for double grafting on the Quince. This Pear bears a melting fruit, quite late in ripening, and remarkable for its abundant juice and acidity, so as to be scarcely eatable. This is employed as an intermediate stock for such Pears as Summer Doyenné, Citron des Carmes, Williams's Bon Chrêtien, and some other kinds of Pears that require their luscious flavour corrected. As the knowledge of the peculiarities of this intermediate stock (a new variety) has been the result of some close observation, I was not surprised to find its name withheld. For, as Mr. Rivers observes, the appropriation of a new idea without acknowledgement or gratitude is too common at the present day with horticulturists of a certain class; but this feeling or failing is very common among all manufacturers.

Mr. Grieve is "unable to say whether or not double grafting of Cherries and Apples has been practised." Mr. Grieve might have spoken more decisively as to Cherries, for they have long been operated upon in England, and are mentioned by Mr. Rivers in his book. The stock employed is the Cerasus Mahaleb, on which the old Morello, or a variety of it, is budded. The latter is a sort that was raised at Frogmore, remarkable for its vigorous growth, its habit of blossoming abundantly and never bearing any fruit, or, at least, very few. On the young shoots of this kind varieties of the Bigarreau and Guigne Cherries are budded or grafted. This mode of cultivation gives a comparatively dwarf habit to those vigorous-growing sorts, and makes them better adapted for garden trees as pyramids and trained trees, than when grafted on the common black Cherry (Cerasus sylvestris).

With respect to double grafting the Apple, there does not as yet seem any advantage to be derived from it, as the English Paradise stock produces in all our soils and climates such healthy garden trees. I have, however, tried the experiment of grafting that well-known dwarf and prolific sort, the Hawthornden on the Crab, and then double grafting the young shoots with the Blenheim Pippin, and one or two other vigorous-growing sorts. The experiment has been in progress two or three years, and it seems as if the intermediate Hawthornden stock had imparted to a certain extent its dwarf productive habit; but it is yet too early to judge of the effect of this mode of culture.

Referring again to Pears, there is not the least doubt but that many sorts may be improved by double grafting; time and close observation are both necessary to select the sorts and the stocks, so as to regulate the flavour of the fruit. This may seem chimerical, but it may prove very much the contrary.—Observer.

EAST LOTHIAN STOCKS.

I can strongly endorse all that Mr. Thomson has said in favour of these splendid acquisitions to the garden, either for bedding, pot plants, or cut flowers. When I visited Archerfield last autumn, and saw the long lines of them standing up boldly like gigantic Hyacinths, I felt that my journey was more than repaid by seeing them alone.

However, I was sceptical of being successful with their culture, knowing that so many had failed in other localities. I am a believer that soil and locality affect many kinds of plants.

Mr. Methven, of Edinburgh, sent me packets of the various kinds for trial—viz., purple, scarlet, and white. I sowed the seed in gentle heat about the end of March, and gradually hardened the seedlings off, and some time in April they were pricked out into light soil placed over a layer of rotten manure, somewhat in the way we are accustomed to treat Celery. The protection afforded was a sunk pit with boarded covers, which were used against frost and heavy rains. About the end of May the plants were lifted carefully with good balls and planted in well-manured ground; a thorough soaking of water was given to the ground both before and after planting, and the result is, out of a hundred of each kind planted in long bands, each colour separately, there has only one single flower appeared. They are branching and flowering very freely, and the effect is beyond anything I ever anticipated. The position is an exposed one,

and 300 feet above the level of the sea. If the true seed can be secured, I feel certain the plants will give satisfaction to the most fastidious.—M. Temple, *Balbirnie Gardens, Markinch, N.B.*

THE STRAWBERRY CROP OF 1869.

Another Strawberry season is over, and a very trying and peculiar one. Where the plants had been taken care of, and not allowed to suffer from the drought the previous season, there was an abundance of bloom, but a continued succession of cold east winds prevented the flowers from setting. Premier, President, and Sir J. Paxton suffered the most, not because they flowered earliest, as Black Prince, which flowered before them, had a good crop of fine fruit. The remarkably fine weather about the middle of April started the plants into rapid growth, and also into flower earlier than usual, only to be blackened by the frosts in the end of April and beginning of May. Notwithstanding all drawbacks I picked good fruit out of doors, especially of Dr. Hogg, British Queen, Sir Harry, and La Constante; the last-named variety was more acid than I ever had it before; it had the best crop of fruit, however.

By far the best fruit was this year obtained from pot plants. Premier, a beautiful Strawberry, but rather acid, was the first to ripen in the orchard house about the last week in May; this variety is rather acid, but it is very hardy, also vigorous and prolific. The next in succession were Sir J. Paxton and President in the first week in June. La Constante was latest, the first week in July; at the same time I picked Premier and President out of doors.

The sorts I will now add to those I have already enumerated in the Journal are Cockscomb, Souvenir de Kieff, and President Wilder (De Jonghe), said to be a great improvement on La Constante, both in respect to beauty and flavour.

As regards the cultivation of Strawberries in pots, I am very much in favour of putting them early into the fruiting pots, potting them firmly, and standing them in a position, if possible, fully exposed to the sun. By attention to these simple directions, during the last two seasons I had not five plants in five hundred which did not carry a good crop of fruit. It is very annoying, after growing the plants until they throw up their trusses, to have 25 per cent. or more which have nothing but leaves.

The best material for potting the plants in is good loam and rotted farmyard manure. I layer the runners in 3-inch pots, and shift into 6 and 7-inch pots as soon as the plants are established, and they ought to be all in their fruiting pots by the middle of August, whether for early or late forcing.—James Douglas.

CULTURE OF MARÉCHAL NIEL ROSE.

I quite agree with the Rev. W. F. Radclyffe that the Maréchal Niel Rose succeeds best against a south wall. I have a plant here which has had from fifty to sixty flowers on at one time, and some of them very large. It is generally in flower by the end of May or beginning of June, but the bushes in the open ground do not flower till a much later period, and grow more to wood. I find it is a Rose which likes to ramble, and to have only a little stopping and thinning. No one need despair of success with this beautiful Rose if he plant it against a south wall, and do not use the pruning knife much.—J. H. S.

ONION-GROWING ON LIGHT LAND DURING A HOT SEASON.

During the extreme heat of the summer of 1868, amongst other things which suffered with us were the Onion crops. Our general crop came up well, and held on well for some time. About the 10th of June we had a few very refreshing showers, being, indeed, the only rain which fell for months. I took advantage of these showers to transplant as many of the Onions as possible from the seed beds, leaving enough for a crop. This is a common practice of mine when I have any spare ground suitable for them. A piece of ground being fresh dug and well manured, I had it several times regularly and firmly trodden all over; I then drew lines 2 or 3 inches deep with a hoe, and into these I placed as many Onions as I could, at from 4 to 6 inches apart. The dull weather which prevailed favoured this operation very much, and besides this, I quite filled these little ruts with water directly after planting, and two or three times a-week afterwards. The Onions grew well and became a good crop. Of course, the edges of the little ruts crumbled in, and after the first hoeing became nearly level, consequently nearly covering the Onions when full-grown; but these, nevertheless, repaid all the care bestowed on them; whereas, scarcely any of those in the seed beds, although they had equally good treatment, grew larger than those generally used in pickling. I attributed the difference in the results principally to the fact, that the transplanted Onions were placed deeper in the soil than the others, so that their roots were not so much scorched during the hot weather which followed.—G. Dawson.

ORCHARD-HOUSE FAILURES.

With regard to the minimum temperature observed in the cast-iron orchard house at Scone Palace (see page 75), you must have misunderstood me. What I wrote I cannot now say. What I meant was 21° below the freezing-point, or 11° Fahr. Twenty-one degrees is so common inside the house during the flowering season, we think nothing of it. When speaking of freezing temperature we invariably say so many—so many degrees of frost, or indications under 32° Fahrenheit, being understood.

It might have been added that the said low temperature having been followed by a clear hot day, the maximum heat under the structure would range from 100° to 120°, from which it would appear that if sudden alternations from low to high temperatures, and *vice versâ*, are injurious, it will very much depend on what sort of heat it is.—H.

AMONG THE SWISS LAKES.—No. 3.

One of the peculiarities of alpine districts is the inability of the human eye to appreciate the vastness of the elevations. I was at the foot of the Jungfrau, which rises to the height of 12,852 feet, yet it certainly did not seem to me so much higher than Snowdon, which is only 3567 feet. One of the most striking evidences of great elevation is noted by Mr. Macmillan, who observes that on Mont St. Bernard, at an elevation of 8000 feet, "water boils at about 187° Fahr., or 25° sooner than the normal point; and in consequence of this it takes five hours to cook a piece of meat which would have taken only three hours to get ready down in the valleys." Though the total of the elevation is so difficult to appreciate, the steepness of their sides is not at all doubtful, especially to pedestrians. Yet on these slopes, which no Englishman could mow, hay is made; but as no vehicle could rest upon them, the hay is carried home in bundles, enclosed in nets on the backs of men and women. It is stored under cover, for, in this land of universal pasturage, such winter fodder is more valuable than the scanty grain crop. Pursuing any occupation under difficulties, invariably leads to assistant inventions which would never be suggested were the occupation untrammelled by obstacles. One instance I observed where watering was needed on a hill slope, and the crops were in drills. A narrow four-wheeled dray had to be employed for conveying the water. One large vessel for holding the water would have been unmanageable, so there were in the waggon three casks connected by leather pipes, and the water was delivered to the crop through a tap and hose attached to the end head of the last cask.

Wood is the universal fuel, and it is chiefly of the Beech, which usually clothes the base of each mountain, as the Abies excelsa, or Norway Spruce Fir, exclusively occupies its higher portions.

The cottage gardens are small, but well stocked with the vegetables most common in England. The only crop unusual with us, but almost universal in the Swiss gardens, is the White Beet. It also is peculiar to see large patches of Dandelion cultivated in corners of fields. It is used for salading.

Honey is a perennial occupant of the breakfast table, and is of excellent quality and flavour. The bee hives, all on the old pit-and-brimstone system, are ranged on a shelf against the side of the house, about 6 feet from the ground. I saw none otherwise placed.

The employment of the dwarf Palms as room plants has often been recommended in your pages. In Switzerland and other parts of continental Europe no such recommendation is needed, for they are so employed very generally. Even on the *table d'hôte* of every respectable hotel they are common. The Corypha australia is the species usually employed.

I have now turned over the last page of my note-book, and its first line is inscribed "Lausanne—Vevay." Indifferent

though they are, yet here are produced some of the best of the bad Swiss wines. Vevay is *the* vineyard district of the cantons. Here is "L'Abbaye de Vignerons," or Guild of Vine-cultivators; and its motto, "Pray and Labour," is an admonition applicable to all the affairs of life. This guild bestows medals and other marks of honour upon the most skilful Vine-cultivators. At intervals of about fifteen years, also, a public festival is held, in which the most successful of the vineyard keepers is crowned, and borne in a procession, accompanied by various characters associated with the history of the Vine—such as Bacchus, Noah, Silenus, Pomona, the spies who returned from Canaan bearing Grapes, and many others. On this occasion, too, the prettiest and most worthy maiden of the district is dowered and married to her accepted lover.—G.

PAPERS READ AT THE HORTICULTURAL CONGRESS AT MANCHESTER.

NOTES UPON ORCHIDS.

This is, undoubtedly, the city above all others in the United Kingdom, round which Orchid-growers seem to congregate, and many are the fine and extensive collections to be met with in the neighbourhood. I feel in opening this subject here I have undertaken a heavy task, though at the same time a very popular subject. When I first laid before the Orchid world a few simple rules for successful cultivation, very few Orchids were known, and their habits and mode of growth in a state of nature even less so, and the consequence was, they were found very difficult to establish in our plant houses. By steady perseverance, however, the mastery was gained over a few plants, which from time to time opened their curious, beautiful, and, in some instances, delicately-scented flowers, each fresh kind that revealed its beauties only increasing the desire for more. This desire has certainly been gratified in a most extraordinary degree during the last few years, by the immense quantities of Orchids sent to us from their native habitats by various collectors, until at the present time there can be little short of two thousand species in cultivation in European gardens, many of them producing flowers of surpassing beauty, whilst those of others are of small size and dull in colour, which, though not producing much effect, are generally exquisitely coloured, curiously formed, and present a beautiful appearance when viewed with a microscope or ordinary pocket lens. These small-flowered kinds will naturally enough be discarded by the amateur with limited space, but the whole of the species should be carefully preserved in our large botanic gardens, for none is more fully aware of the value of some of these small kinds for determining the limits of genera and species, and none knows the value of living specimens for this purpose better, than the systematic botanist. It is not my intention, however, to occupy time with the history of the introduction and establishment of tropical Orchids in European gardens, although many curious facts are connected therewith, but to offer a little advice upon their management—to repeat, it may be, the same things that many here may have heard me insist upon before, and which, therefore, are not new to them; but there may be many young beginners in Orchid-growing, who will, perhaps, find something to assist them in the prosecution of their hobby.

Orchids take first rank amongst all the plants cultivated in our gardens, for their extreme beauty and the peculiar and interesting structure of their flowers. They are found in nearly all parts of the world, and are divided into two large sections—viz., Epiphytal and Terrestrial. The plants comprising the first section are the most showy, and are found in tropical countries, growing in the forks, or upon the branches of trees, at various elevations, whilst the terrestrial Orchids are mostly found in the more temperate regions, burying their roots under the surface of the ground, many of them losing their growth during the winter months.

The growths of orchidaceous plants are called pseudobulbs; but it has occurred to me very frequently that such distinct forms of growth as Dendrobium, Odontoglossum, Cattleya, Sobralia, Grammatophyllum, Barkeria, Epidendrum, Catasetum, and many others which are equally dissimilar, require some more descriptive term than that which is applied indiscriminately to all. In the eastern world epiphytal Orchids are mostly represented by such forms as Vanda, Acrides, and Dendrobium, whilst in the western hemisphere thick fleshy growths are the rule. True, some few genera in the east, such as Cœlogyne, Bolbophyllum, Eria, and a few others represent this form, but they are exceptional. I do not intend giving in detail the cultivation of this my favourite class of plants, because my views upon this subject have been for some time prominently before the Orchid world, first in the pages of the *Gardeners' Chronicle* under the title of "Orchids for the Million," and more recently in my three editions of the "Orchid-Growers' Manual," and in Warner's "Illustrated Select Orchidaceous Plants." The conditions which I laid down at the very first were moderate heat, an abundance of fresh sweet air, and moisture, with full exposure to the light, but shaded from the direct rays of the sun, and I have never had any reason to change these rules. I carefully avoid extremes of temperature; by this means I seldom have a plant which shrivels, or becomes stewed with heat, or which is starved and perishes through cold; and by giving plenty of fresh sweet air, and keeping it properly charged with moisture, they never have the "spot." Spot is the great bugbear to Orchid amateurs, and, indeed, to many old-established Orchid-growers; but it need not be dreaded if the previously mentioned rules be followed, and care be taken that no rotten or rotting material is near the roots, either in the shape of sour stagnant moss or soil, or decomposed wood.

I am quite aware that some eminent men pronounce this disease infectious and difficult to cure, and that it is produced by the growth of a minute fungus. That the spot marks on the leaves are caused by a fungus I firmly believe, but I also as firmly believe that spot is the result of bad health, and not the cause of it; for before the fungus can gain a footing, the plant or plants must have been ruined in health, and have thus become a fitting receptacle for the spores of the parasite to germinate upon. Respecting its infectious character I am a total unbeliever. If plants in bad health stand with those which have already become spotted they will become infected as soon as any spores alight upon them, because they present the proper conditions for the germination of the spores; but if a healthy plant be set side by side with a spotted one it will not be harmed. This I have thoroughly tested with my own plants, and have had ample opportunity of watching it with other collections, and can therefore speak upon the matter with confidence. If a plant infested with spot be by chance introduced into a collection entirely free from the disease it may be readily cured, but not freed from the marks already upon the leaves. To destroy the disease let the plant be taken out of the material in which it is potted, or if on a block of wood let that be removed; then cut away every particle of decayed or decaying roots, wash the plant and roots thoroughly, and replace it in some good, sweet, living soil; at the same time attend carefully to the advice previously given regarding the atmosphere and temperature, and the probability is it will not be long before the plant is again in perfect health. I have adopted this treatment with perfect success myself for the last twenty-five years, and am therefore advising a system which I have thoroughly tested, and am not propounding a theory. Whilst speaking of theories, I cannot help here expressing my surprise that many of our leading Orchid-growers have been so reckless with their valuable plants, and have suddenly given over their whole collection in good health, to test some theory propounded by those who have probably never tried it themselves. I allude to such as double-glazed houses, exposing plants in the open air during frost, potting in cocoa fibre and in potsherds, and many other whimsical things. Many persons still fight for and uphold these practices, and are continually persuading their friends to adopt them. Now, my advice to all Orchid-growers is, If your plants are thriving, be careful not to risk their welfare for the sake of experiment. If you must test theories, do it with a few common plants, and not risk your collections as many have done during the past few years, for I can assure you I have seen several fine collections, both private and public, ruined because they have been subjected to trials of many theories of treatment.

It is a fact that many of the older cultivators of Orchids seem to have become indifferent to their charms, and in some instances have relinquished their culture entirely. One great reason for this has been the sickly appearance of the plants through excessive fire heat, which at the same time renders the houses unbearable, and consequently the plants have been discarded. Another reason has been through amateurs buying hundreds of newly imported plants of one species, which overcrowd the houses. No extra means of looking after them are provided, and when they become unhealthy through want of room and cleanliness they are discarded in disgust, because a thousand plants do not look so well in the same space, and with the same care, as a hundred did. The cool system, as it is called, has been another source of great annoyance to many, but if carried out in a proper manner it greatly enhances the value of this beautiful tribe. Many, however, have launched into extremes, and cruelly deceived young beginners especially, by assuring them that such and such species will grow in an ordinary greenhouse, or even out of doors. These assertions being acted upon, the plants naturally enough drag out a miserable existence, and ultimately die. Now, an ordinary greenhouse is a house in which Pelargoniums, Ericas, and Fuchsias grow and flower, and I deny the possibility of any epiphytal Orchid continuing long in health under the same treatment and in the same atmosphere as these plants enjoy. That many kinds will succeed in as low a temperature I readily admit, but they require less of the blazing sun. They must also have a much moister air, and the sashes of the house must not stand open, as they do under ordinary circumstances, otherwise the leaves will soon shrivel and curl up, when, as a matter of course, death soon follows: therefore I contend it is wrong to assert that epiphytal Orchids will succeed in an ordinary greenhouse. I find, almost as a rule, that the species enjoying a low temperature do not require a decided period of rest, like those from hotter parts, but that a temperature ranging from 45° to 50° in winter, with moderate moisture, and as little above 65° or 70° in summer as possible, will keep a vast number of those denominated "cool Orchids" in perfect health; and as I am of opinion that greater damage may result from the temperature sinking a few degrees below the minimum than rising above it, I never rush to the lowest possible degree; but if amateurs would take an interest in knowing something of the history of their plants and bring their reason to bear upon the facts, they would soon learn where and under what treatment they succeed best.

But whilst we are thus so strenuously advocating the cultivation of cool Orchids, I must put in a plea on behalf of the East Indian kinds from the low or hot parts, for I am under the impression many are discontinuing their growth because the houses require to be so hot, and are, therefore, not enjoyable. This, however, need not be the case; some of the most beautiful Orchids known are found among the Vandas, Aerides, and Saccolabiums, and they will both grow and flower profusely in a lower temperature than many imagine; in winter, with the house ranging from 60° to 65°, they will enjoy robust health, and in summer with 65° for the minimum. A collection of East Indian Orchids, which I saw recently, perfectly astonished me; the house was unbearable; I can compare it to nothing but an oven, and very little or no air was admitted. The consequence was, no one could remain in the place even a few moments with pleasure; indeed, if Orchids required such an atmosphere, I should myself be the first to discard them; and how men who profess to have a knowledge of these plants can commit such grave errors, it is difficult to understand; beginners might be excused for doing such things, but even they, one would imagine, would soon learn to correct such blunders.

With respect to terrestrial Orchids, comparatively nothing has been done; but, as a class, they have been very much neglected, for no other reason, so far as I know, than people imagine they are difficult to cultivate. This is the opinion of thirty years ago, and I do hope to see more of these beautiful plants grown than has ever yet been attempted. There are many Disas, Satyriums, Pogonias, Epistephiums, Habenarias, Pterostylis, &c., that we in our philosophy have never dreamed of, which will be perfect gems if properly established in our gardens. One cause of failure I have noticed, and that is the complete baking they usually get in the winter season. In their native habitats some roots will, undoubtedly, be deep in the moist soil, although the top is parched and burned. This is not taken into consideration, and the plants with us get dried to powder. Many of these kinds succeed well in cold frames, others thrive well with such plants as Odontoglossums, whilst others, again, require the warmth of the East Indian house. They require an abundant supply of water, with ample drainage to carry it away quickly, and insects must be vigilantly looked for and speedily destroyed. This applies to Orchids generally, otherwise they will soon fall into bad health. I consider it a sure sign the collection is larger than can be properly managed when the plants become infested with these pests.

In conclusion, I have no hesitation in saying no class of plants yield such gorgeous, chaste, elegant, and curious flowers, while none can compete with them for fragrance. The impression that Orchids are difficult to grow is fast becoming exploded, and I wish to destroy that impression entirely as speedily as possible, for nothing is farther from the truth. My own practice for very many years proves to me that if moderate artificial heat be applied, a liberal supply of fresh air given, which must be properly supplied with moisture according to the season, using for potting material good live sphagnum moss and fibrous peat, no difficulty whatever will arise in the cultivation of these plants.

In collections of any plants, death and disease will occur sometimes, and therefore a collection of Orchids should not be expected to be exempt any more than other classes of plants; but if care is taken this will be nothing serious, for they certainly will withstand more ill treatment than most plants before they quite die. In a few words, therefore, to keep your Orchids in a healthy and satisfactory state, I say, Provide moderate-sized houses for them in preference to large ones; give only a moderate supply of fire heat; let them be abundantly but judiciously ventilated, and the atmosphere sufficiently charged with moisture to yield nourishment to the plants, and everything in connection with them in a sweet and living state, avoiding anything in the shape of decay as one would a pestilence, and nothing more will be heard or said about the difficulties of Orchid cultivation.
—B. S. Williams, *Victoria Nursery, Upper Holloway, London.*

ON THE CULTURE OF CHRYSANTHEMUMS.

It is well known in the horticultural world that in the dull months of November and December the Chrysanthemum assumes an undoubted sway in the conservatory; and I am confident that all who have once witnessed the gorgeous panorama of colours which a conservatory full of well-grown Chrysanthemums presents at that dull time of the year, when flowers are so scarce, will agree with me when I assert that there is no decorative plant more worthy of general cultivation. It is, therefore, surprising to find that a plant so highly valuable for in-door and out-door decoration should not ere this have received more marked attention.

Since the introduction of the new Japanese varieties Chrysanthemums may be divided into three principal classes—viz., Large-flowered, Pompons, and Japanese. From Chrysanthemum sinense, introduced into this country from China in 1764, were produced our Large-flowered varieties; from the Chusan Daisy, sent home by that famous collector Mr. Fortune, originated the Pompons; and the new Japanese varieties were raised from seed by Mr. Salter, of Hammersmith, from Chrysanthemum roseum punctatum, a native of Japan, likewise introduced by Mr. Fortune.

In this paper I purpose to divide my remarks into two parts—first, that relating to out-door cultivation; secondly, on cultivation for the conservatory and for exhibition. I wish it to be distinctly understood that the observations which I am about to advance will be of a purely practical character, or confined to matters which have come under my personal experience.

In briefly alluding to out-door cultivation, after five years' practical experience in Hampshire and the same in Lancashire, I find by careful observation that the Chrysanthemum blooms nearly two weeks earlier in the former than in the latter county, and about ten days later in Perthshire and Forfarshire than in Lancashire. From this it will be seen that the Chrysanthemum will amply repay any labour bestowed on it out of doors from Lancashire to Hampshire, more especially in the southern counties, for with protection from frost a good display may be maintained from the beginning of November till Christmas; but much display cannot be expected from this plant cultivated out of doors in latitudes north of Lancashire, as in many parts of Scotland no reliance can be placed on its flowering at all out of doors, and in some places there in late seasons it requires no small amount of cultural skill to bloom it even under glass.

No grower has obtained greater celebrity as an out-door cultivator of this plant than Mr. Broome, of the Temple Gardens, London, where he grows thousands of Chrysanthemums annually, which are the daily admiration of thousands of visitors when no other flowers can be seen out of doors.

I will speak of the propagation of this plant, also of the treatment of the young plants, under the second division of my subject.

Presuming that the plants have been kept clear of insects during the winter months, they may be planted out in the open ground in the end of March or beginning of April. In preparing the borders for their reception it is necessary to deeply dig the ground, mixing with the soil some rich loam, a little well-decayed manure, and some lime rubbish. They will grow in almost any soil, but by this preparation better blooms will be insured. After the plants are fairly started into growth great attention must be paid to watering, for if they are allowed to flag they will become bare at the bottom. To prevent this, it is good policy to mulch well. When the plants advance in growth, in order to prevent the wind breaking them, they should be secured with sticks. Two stoppings will be sufficient for them in the south, but none is requisite in the north. They should be syringed with clean water twice a-day. In September they generally show their flower buds, at which time liquid manure should be supplied. That from the farmyard will be found suitable if no better is at command, if well diluted with clean water—say four or five times as much of the latter as of the former, according to strength. Reference will be made to this presently. They may have this liquid preparation at every alternate watering until the blooms begin to open, when it must be discontinued. Every available means should now be employed to preserve the beauty of the plants and to prolong their blooming period. This may be secured by covering up in frosty weather with tiffany, calico, &c. By attention to this, as I have said, a tolerable display may be kept up out of doors in mild winters till Christmas.

I now come to the second division of my subject—viz., cultivation for the conservatory and for exhibition, and I will submit the substance of my mode of culture in this county.

I may say that old plants cut down and treated the same as Pelargoniums, if they break well, generally make the best specimens; but they are not to be much depended on, for it frequently happens that when a plant is in full bloom one or several shoots die off suddenly, thereby spoiling the specimen. As early in November as suckers can be obtained from the old plants they should be taken off, with a little root if possible, choosing the strongest, and rubbing off all eyes at the bottom of the sucker, after which they should be inserted singly in thumb pots in a compost of one-half loam and one-half leaf mould, with a sprinkling of silver sand. After a gentle watering they should be placed in a cold frame, plunging the pots in ashes or any similar light material, keeping them close to the glass and well syringing for two or three weeks, when they will be found to be rooted. A little air may then be given, gradually increasing the quantity until the young plants are sufficiently hardened, and still syringing them frequently in mild weather. By the middle of December the roots will have reached the sides of the pots, when the plants may be shifted into 3-inch pots, using less leaf mould in the compost than formerly. After this time they must have plenty of air on all favourable occasions. Although they will not grow much in the winter months, yet if kept close to the glass and in a sunny situation, with a lining of hot manure round the outside of the frame, and covered up at night, they will keep gradually moving; for the sooner the specimens attain the desired size the earlier the stopping may be discontinued, thus giving the grower more time to thoroughly ripen the wood, which I maintain is of the very first importance in Chrysanthemum culture, and without which no grower can produce satisfactory results. As soon as the plants have attained the height of 4 or 5 inches their points should be pinched out, which will cause them to throw out several side shoots. All shoots after this time should have their points nipped out after they have made four joints, until the plants have reached the desired size.

About the middle of January the roots of most of the plants will again have reached the sides of the pots, when they should have another shift, using oyster-shells for crocks, and giving plenty of drainage. At this time I make up the compost which is used at every future shift. It is made up in the following proportions—three parts turfy loam, and the fourth part one half leaf mould and the other half pounded oyster-shells, lime rubbish, and silver sand in equal proportions. The

loam is pulled to pieces by the hand and wireworms destroyed. Where bone dust can be had it is preferable to oyster-shells, using it in the proportion of about 1 to 80. The system most generally adopted is to grow the plants to one stem, and now is a good time to rub off all eyes for 2 inches above the soil.

Towards the middle of February the plants will require another shift, always watering sparingly after shifting until the roots begin to work in the new soil. They will now begin to grow rapidly, when pegging-down must be had recourse to, continuing the same treatment, and fumigating occasionally to keep them clear of insects. About the middle of March they will be ready for another shift, after which any weak shoots ought to be allowed to grow upright for a time, so as to throw more strength into them, at the same time tying down the strong ones to counteract their inclination to grossness, for it is of primary importance to have all the shoots of uniform strength, otherwise there will be a diversity in the size of the blooms.

The grower must now decide in what shape he intends to train his plants. This should not be delayed too long, for as the season advances the shoots become harder, stiffer, and consequently more brittle, and frequently the breaking of a shoot at this stage spoils a specimen for the season. There are so many fantastic shapes into which the Chrysanthemum may be trained, on account of its extreme adaptability to almost any mode of training, that I refrain from recommending one more than another; I would, therefore, say, Let every grower train according to his requirements, or as his fancy may dictate. After trying the upright, squat, pyramid, standard, and convex forms, I will merely say that I have found the last a very simple and effective mode of training. Round the rim of the pot a wire is fastened, to which the shoots may be tied. In bending the shoots down, they may be left a little higher in the centre; one shoot can by this method be tied to another, and the framework of the specimen will, with very little trouble, be formed so that any future tying will merely consist in filling-in the spaces between the shoots.

By the last week in April the plants will, by good management, be ready to receive their final shift; the large-flowered ones into 12-inch, and the Pompons into 10-inch pots. The plants should now have plenty of room, and should be syringed regularly morning and evening. In May they should be gradually hardened-off, previous to being removed out of doors, by taking off the lights during the day.

About the end of May, or beginning of June, a sunny but sheltered piece of ground should be selected, and the pots should be plunged to three-fourths of their depth, placing a small inverted pot under each to secure good drainage and exclude worms, leaving sufficient space between the plants to admit light and air, otherwise they will become drawn, and weak unripe wood will be the result. The plants will require turning round once a-week. After the pots are full of roots, great attention must be paid to watering, for if the Chrysanthemum is neglected in this particular, it will tell its own tale by throwing off a shower of leaves almost as soon as any plant under cultivation, not only materially detracting from the beauty of the specimen, but exercising a very detrimental effect on the production of good blooms. During June, July, and August but little variation of treatment will be required, only the grower should endeavour to have his plants of sufficient size to enable him to give the large-flowered ones their last stopping in the first or second week in June, and the Pompons theirs in the second or third week.

In August earwigs and caterpillars must be looked after. The former may be caught by cutting bean stalks into lengths of 4 or 5 inches, placing them on the plants, and examining them in the mornings; the caterpillars must be sought for among the leaves of the plants. If the pots be this month lifted nearer the surface, it will facilitate the ripening of the wood; and if any of the plants be inclined to be gross, it will be necessary to withhold water to some extent, in order to ripen the wood before they show their buds, which they will do in the first week in September. Now is the time to apply liquid manure, and in my opinion the Chrysanthemum should never have any of it until it shows its buds. There may be a few exceptions to this rule, but many who profess to be good growers, and who like to see their specimens make luxuriant growth, administer liberal doses of liquid manure during the growing season; nothing can be more fatal to the formation of good blooms.

Disbudding should now commence; and in operating care should be taken in the selection of the buds to be retained, to choose the fullest and most healthy-looking, and leave only one on each shoot of the large-flowered sorts. Some of the Pompons, such as Bob, Mdlle. Marthe, &c., do best by disbudding to one bud on each shoot, and none of them should have more than three left on a shoot. Some of the shoots will be found to be more forward than others, and are apt to bloom before these; but by disbudding this may be avoided, by nipping out the crown or earliest bud of the earliest shoots, leaving a good side bud, and retaining the crown or earliest bud of the late shoots. This will cause all the buds to be equally forward.

About the second week in October the plants should be taken under glass—that is, into houses or pits where they can be protected from frost, keeping them cool and close to the glass, with abundance of air. If they are wanted for exhibition, the earlier varieties may be kept outside for a week or ten days longer, protecting them from severe weather; and, again, the late varieties may be kept in the warmer end of the greenhouse. The plants should now be watered five times a-week with liquid manure, applying it 5° warmer than the temperature of the house. This will concentrate the entire energies of the plants in the buds, which will now be swelling rapidly. Towards the end of the month the large-flowered kinds should be tied to neat green sticks, as the blooms will be too heavy for the shoots to support them. The Pompons will require little or no staking, but should be neatly tied-in, so as to present compact specimens.

In the last week of October, or first week of November, the buds will begin to show colour, when syringing and liquid manure should be discontinued. Any of the blooms that are at this time too late should be nipped off, as it is of importance that all of them should be at the same stage of expansion. I prepare my liquid manure in this manner:—I have a tub which will contain about eighty gallons of water; into it I put one peck of pigeons' dung, over which I pour some boiling water to kill insects, and add one peck of soot, and one peck of lime rubbish. I then fill the tub with liquid manure from the farmyard, stir the contents, and skim off the surface previous to use. I apply this liquid in the proportion of one to six of clear water.

In the autumn mildew is apt to make its appearance, to prevent which the leaves should be dusted with flowers of sulphur.

About the 20th of November the plants will be in full bloom.

By pursuing the foregoing treatment, the cultivator will be enabled to produce large-flowering specimens that will carry one hundred and fifty good blooms, which will require no dressing, and Pompons with from one hundred and fifty to four hundred and fifty blooms, according as they are disbudded; but it is imperative that the grower be to a certain extent an enthusiast, for without enthusiasm nothing great has ever been achieved.

If specimen blooms are wanted, the plants should not be stopped at all, but the side shoots should be allowed to grow upright, disbudding to a limited number on each plant; the fewer left the larger the blooms will be. Treat the plants in every other respect as recommended for specimen plants. Incurved varieties are best for this purpose. They are also more in request now for specimen plants. Some of the sorts, such as Golden Trilby, Princess of Wales, &c., do much better in some years than in others.

Anemone-flowered varieties, although more tender than the others, are very beautiful, and well worth growing.

I will not occupy time by giving a list of what I consider the best varieties, as the various catalogues sufficiently describe the most desirable.

In conclusion, I consider the new Japanese varieties a great acquisition to the conservatory, for although they do not come up to the standard of what is called a "florists' flower," they possess the much-desired quality of being late bloomers. This, then, is already one point gained, for it is a greater desideratum to have late-blooming Chrysanthemums than early ones, as flowers are not so scarce in the autumn months as they are in January and February; and as the natural blooming time of the Chrysanthemum is November and December, something is wanted that will bloom naturally for two or three months after Christmas. This, I think, will soon be accomplished by improving on the Japanese varieties. It is true that by growing some of the early and late kinds, and with the assistance of forcing and retarding, the blooming season of the Chrysanthemum may at the present time be extended from September till February; but as it is forced or retarded its blooms will be proportionably inferior, for it despises the forcing pit as much as it dislikes the retarding house, thus affording one more proof that Nature will not be trifled with in any of her grand and varied arrangements. I trust that not only a greater stimulus will henceforth be given to the cultivation of the Chrysanthemum than has hitherto been accorded it, by offering more liberal prizes for it at exhibitions, but that encouragement will be held out to raisers of late-blooming kinds by offering premiums for late varieties of the Japanese race, whose natural blooming time will be from Christmas onwards, and I have no doubt that we shall have the blooming season of the Chrysanthemum carried fairly into March. It will then, with its beautiful and diversified colours, monopolise in brilliant array the most distinguished places on the stages of the conservatory, for at least four or five of the most dismal months of the year. I hope that such a time is not far distant, and that this truly magnificent flower will occupy that superior standing in the floral kingdom which it so well deserves.—R. FLEMING, *Gardener to R. Houghton, Esq., Sandheys, Waterloo, Liverpool.*

SMOKE VERSUS VEGETABLE LIFE.

HAVING been employed for more than twenty years in the midst of a manufacturing district, during which period trade has very much increased, and having, therefore, for that length of time had to contend against a gradual increase of smoke and other vapours which are very injurious to vegetable life, I will venture to lay before you a few plain remarks how that offensive and polluted atmosphere has to a certain extent injured, and in several instances destroyed, some of the trees, &c., in this locality.

When I first came to live in Warrington the air was not so full of smoke and other injurious gases as it is at the present time. Some species of plants which then flourished have now disappeared. I have noticed that as manufactories have increased, one species of plant after another has gradually declined in health, and in some instances they are mere skeletons of what they formerly were, giving a desolate appearance to that country which they once beautified.

We all know that some plants are much more sensitive than others to injurious chemical matters in the atmosphere. When I came to my present situation the Fir and Larch were healthy; these were the first to give way, and the first which had to be cut down. Cotoneaster microphylla next died; the Arbor Vitæ, Juniper, Erica, and common Rosemary followed, and what few now exist of these are in a wretched condition; so is Berberis ilicifolia; the Yew, once very vigorous, is all but destroyed; the Rose struggles hard for existence; the Holly is giving way; and none of the Conifers, if planted in these grounds, will live more than two or three years. Many of the forest trees that flourished twenty years ago are gradually becoming weaker every year, as the air becomes more and more filled with obnoxious vapours, and some of them are affected sooner than others. The Sycamore, more particularly the variegated variety, is very tender, it suffers severely; the Hornbeam is fast decaying; the Horse-Chestnut grows vigorously, but is often severely cut while the foliage is young, and never worse than at present; and the Beech and Lime tree are somewhat stronger than the above, though very far from being healthy. The Ash seems to stand best, and the Elm the next; but all of these are dirty, and are injured to a considerable extent.

Among fruit trees, the Pear appears to stand best, but is not up to the mark, and the Plum and Damson moderately well, but they are giving way. The Apple is suffering very much; only young trees are at all vigorous, and these not satisfactory; the full-grown trees are very bad, and the fruit very inferior. The Red and White Currant have suffered severely, being very subject to the attacks of aphides; the leaves then become covered with an adhesive substance, the soot coats them over and chokes the pores, and the leaves falling off in summer, the wood cannot get matured, and the plant ultimately dies. Our Currant trees, that a few years ago were healthy and produced very fine fruit, are now quite ruined. The Raspberry stands pretty well in more favoured times—that is, when the air is moderately free from smoke. The Gooseberry is inferior. The fruit of all these plants would soon be detected in the market as having been grown in a smoky atmosphere.

Many vegetables which grow strongly do well in summer, but when the autumn sets in the air is so heavy, and filled with poisonous gases, that they soon decay. Kidney Beans sometimes drop off as early as October. Cauliflowers do not stand any frost here as they do a short distance from town; even common Winter Greens are injured to a considerable degree, and it is only in very mild winters that the Broccoli keeps alive.

Many half-hardy flowering plants do not prosper. The Pelargonium, which grows the best here, has the flowers often discoloured during the night, if the barometer is low and the air charged with chemical vapours. A few plants stand pretty well; the Rhododendron, Aucuba japonica, and the Hawthorn flourish here. Some species of plants suffer in all parts of the garden, others only in certain parts. Where the Hawthorn, Rhododendron, and Yew are planted side by side, the first two are healthy, the Yew almost dead. We find, too, that where some of the delicate plants are considerably sheltered from the passing vapours, they are somewhat healthier than those more exposed to smoke.

The above remarks have reference only to the grounds on which I am employed, and which are peculiarly situated. Some time ago the town lay to the east and north of the hall and gardens, but now they are surrounded on all sides except directly to the south. Trade gradually increased, and during the last three or four years has rapidly progressed, therefore smoke has progressed too. Some of the works are of a very disagreeable kind, dispersing very obnoxious smells throughout the town, and unquestionably doing a great deal of harm to vegetable life. I have been on the grounds at all hours of the morning and night, and have felt the disagreeable vapours pass in a body when there has been scarcely a breeze; this has been when the atmosphere was heavy and foggy, and it is on occasions like this that the flowers are found to be discoloured in the morning. Sometimes we find the foliage while in a young state cut in a straight line, and this suddenly. Under all circumstances, the trees in the town cast their leaves at least six weeks before those in the surrounding districts, where there are no manufactories. When the wind is from the east we do not suffer so much as when it is from the west, for in the former case it is often sharp, and carries away the smoke, but in the latter it is soft, the air heavy and moist, and the smoke falls quickly to the ground, hanging among the trees, and passing away very slowly; therefore the plants suffer more.

That some works are more deleterious than others we have sufficient proof. On the east side of the town a firm of long standing has lately introduced a fresh branch into its trade. Close to these works are the rectory grounds, which, as well as the land adjoining, are wretched in the extreme; forest and fruit trees, shrubs, &c., are dead and dying: only such as are screened from the works are fit to stand, and even these are looking badly.

The outskirts of Warrington are somewhat better. Several Conifers that will not live at all with us are found in some of the gardens, but not in a satisfactory state. If we go six miles west we come to one of the most desolate places one ever saw, trees and hedges being killed for a considerable distance. The Thorn and Elder appear to be the hardiest; miserable relics of these are nearest to this rising town—Widnes, where chemical works are numerous. If we go eight or nine miles north-west we come to St. Helen's, another town spreading desolation; trees are dying for miles away from it. East and southward of Warrington, where no works are, the country is fertile and the foliage rich.

Plants with smooth, glossy leaves, of vigorous habits, grow best in Warrington. The Oak looks as well in the town as the country, for all of us know this tree in many parts of the country is decaying. With us the Laburnum flourishes, so do the Syringa, the Willow, the Birch, the Ivy, and the Elder. The Privet grows moderately. All vegetables must be vigorous, otherwise they will not stand the smoke. Thirty years ago the farmer grew large quantities of Ridge Cucumbers in the fields, but now he cannot grow them. Gourds will not now grow in the town, unless when the season happens to be favoured by a less amount of smoke than we have on an average.

Under circumstances such as these we can only do our best to grow such plants as will withstand the evil, and ask the manufacturers to assist us by reducing that evil as far as they are able, by consuming the smoke. Some have done so here to a great extent; we must hope others will follow in their steps. We do not know how much might be done through a persevering, ingenious man; many wonderful things have been accomplished, and we cannot tell what may yet be done. The earth is not only given to us for usefulness in bringing food, but also for producing things of beauty and adornment, and it is the duty of every man to try to accomplish these ends.—E. Green, *Gardener to Col. the Right Hon. J. Wilson Patten, M.P., Bank Hall, Warrington*

ROYAL HORTICULTURAL SOCIETY.

August 17th.

Fruit Committee.—G. F. Wilson, Esq., F.R.S., in the chair. Messrs. Veitch & Son sent parcels of their Improved Ash-leaved Kidney Potato, which was found at Chiswick to be very prolific, and when cooked very floury. Mr. Thomas, of Shrewsbury, exhibited a seedling raised from a cross between Arrowsmith's Seedling and Fluke. This is a roundish Potato. Mr. Earley, of Digswell, sent a bundle of Short-horn Carrots, which were highly commended by the Committee for their unusual size. Mr. Eckford, of Coleshill Park, sent a large Lettuce under the name of Coleshill Park Lettuce, which proved to be the Florence Cos. Mr. R. Smith, gardener to T. Nicoll, Esq., Wembly Hill House, Sudbury, sent a Cucumber, supposed to be Long Gun, 28 inches long; but as it was quite ripe, its length was its only attraction. Messrs. F. & A. Smith, Dulwich, sent fruit of Surrey Prolific Cucumber, a good, solid, and heavy variety, not of great length, but of general utility. Mr. Baker, of Honiton, sent two varieties of Cucumber, called Eclipse and Bowden's Long, neither of which was considered an improvement on existing kinds.

Mr. George Lee, of Clevedon, near Bristol, sent branches of Lee's Prolific Black Currant, which obtained a certificate at last meeting. These were sent to show that the fruit hangs well on the tree. The fruit maintained all the good properties which it exhibited at the previous meeting. Mr. McLaren, of Ash Common, Surrey, sent fruiting branches and a dish of fruit of a seedling double-bearing Raspberry, to which a first-class certificate was awarded for its robust habit, fertility, and size of the fruit. Mr. Cooling, of Bath, sent fruit of Brailbrook Seedling. This Apple has been sent on various occasions, but never before in condition to enable the Committee to form a decided opinion. It was now shown in good condition, and in the opinion of the Committee was not of sufficient merit to warrant a certificate. Mr. Dry, of Hayes, Middlesex, sent a dish of a seedling Plum, which has been several times before the meeting. It is a large, oval, purple Plum, of excellent flavour, early, having been grown as a standard. It was awarded a first-class certificate, and was named Dry's Seedling. Mr. Fenn, The Rectory, Woodstock, sent twelve sorts of Gooseberries, to show that some of the largest size are not so deficient in flavour as it is generally supposed they are. The whole of the varieties sent being rather over-ripe, the Committee could not form any judgment on their merits. Messrs. Lee, of Hammersmith, sent fruit of the Royal Vineyard Fig, a medium-sized, long, grizzly Fig. The flavour was good, but it was recommended to allow any opinion upon it to stand over for a fortnight, when the collection at Chiswick will be in fruit, and a comparison can be made. Mr. W. Bull, of Chelsea, sent fruit of a scarlet-fleshed Melon, called Nonpareil, which did not possess sufficient merit.

Messrs. Standish, of Ascot, sent a dish of Gloede's Perpetual Pine Strawberries, from runners planted in May. Mr. McIndoe, gardener to the Archbishop of York, sent a dish of large and very fine fruit of St. Ambroise Apricot, which were highly commended. It is a large, handsome Apricot, inferior in flavour to Moorpark, but is a fortnight earlier. Mr. Fairbairn, gardener to W. Death, Esq., South Lodge, Bishop Stortford, sent a splendid fruit of Enville Pine Apple, weighing 9 lbs. 5½ ozs. It was awarded a special certificate for superior cultivation. Mr. Carmichael, gardener to H.R.H. the Prince of Wales, sent a bunch of Muscat Champion Grape, the berries of which were of very large size, and the flavour excellent. Alexander Scrutton, Esq., of Blackheath Park, sent three very fine bunches of Black Prince Grape. Mr. Goode, of Melchet Park, Romsey, sent three large bunches of Duchess of Buccleuch Grape. Mr. Melville, of Dalmeny Park, sent fruit of a seedling Grape, which was so much damaged as to destroy the flavour. Mr. Pearson, of Chilwell, brought several varieties of seedling Grapes, three of which were considered

by the Committee to possess some merit, and recommended that their cultivation be continued. One was a white with a long bunch and a Frontignan flavour, another with a Muscadine flavour, and one somewhat in the way of Morocco. There were besides five other varieties, some of which were raised from the Strawberry Grape, the flavour of which was particularly rich and novel. The Committee highly commended the collection, and were of opinion that the three first noticed should receive special attention.

Floral Committee.—Rev. J. Dix in the chair. This was one of the best meetings of the year. The exhibition of Gladioli and the good old Hollyhock were a treat in themselves, and had there been proper and sufficient space for them, they would have been much more effective. Of seedling Hollyhocks there were none of sufficient merit, or superior to older kinds. Messrs. Kelway were awarded three first-class certificates and one second-class certificate for seedling Gladioli. There were many other seedlings sent, but far behind those which received awards.

Mr. Bull received first-class certificates for Encephalartos grandis, Encephalartos plumosa, Macrozamia excelsa, and a new gigantic form of Aroid, introduced by Dr. Seemann. The plant was recognised, but the specific name could not be remembered. A special certificate was awarded Mr. Bull for a collection of Orchids. Mr. Williams, Holloway, received a special certificate for a collection of Orchids, and a special certificate for a finely-grown specimen of Lapageria rosea.

Mr. Green, gardener to W. W. Saunders, Esq., received a first-class certificate for a most graceful climbing Asparagus. This plant was trained on a strong cord, to which it readily attaches itself, and enables the cultivator to adapt it to any situation he pleases without any fear of breaking or injuring the plant. Messrs. Downie, Laird, & Laing received first-class certificates for hybrid Nosegay Zonal Pelargonium Lady Hawley, dark crimson; also for Stanstead Rival, a light orange-scarlet Zonal. Mr. Goode, gardener to the Dowager Lady Ashburton, received a special certificate for the finest specimen of Lilium auratum ever exhibited. One bulb had divided into ten or eleven flowering stems, producing one hundred and fifty flowers. It was most magnificent; it was one of the pale-spotted varieties. It was commended as worthy of the Lindley medal, which was unanimously awarded. The Society must feel deeply obliged to the Lady Ashburton for her kindness in sending so valuable a plant to the meeting; the packing and conveyance must have entailed considerable trouble. A fine specimen of Lælia elegans Turneri, exhibited by the same lady, was awarded a special certificate.

Messrs. Lee, Hammersmith, received a special certificate for a collection of succulent plants, consisting of Echeverias, Sempervivums, &c.; they also sent a collection of Centaureas, which were not considered sufficiently distinct. Mr. W. Paul, Waltham Cross, was awarded a first-class certificate for a very useful decorative shrub, Euonymus flavescens. Mr. C. J. Perry, of Castle Bromwich, received a first-class certificate for Verbena Ada King, and a first-class certificate for Thomas Lawden; Messrs. Kelway similar awards for seedling Gladiolus Medina, Cherub, and Accius; and a second-class certificate for Freemason. Mr. C. Chater, Saffron Walden, was awarded a first-class certificate for a new, dwarf, beautiful, free-flowering Ageratum, Imperial Dwarf. This was much admired, and will prove extremely useful for bedding purposes. Mr. Eckford, gardener to Lord Radnor, Coleshill, received three first-class certificates for seedling Verbenas of considerable merit—viz., Harry Eckford, Eclipse, and Lady Anne Speirs.

Messrs. Veitch exhibited a large and beautiful collection of Gladioli not for competition.

Mr. Porter, gardener to E. Benham, Esq., sent seedling Hollyhocks. Messrs. Lee exhibited a showy tricolor Zonal Pelargonium called Edward Milner; Mr. W. Paul four seedling Zonal Pelargoniums—Sultana, Lord Falkland, Empress, and Comet; also an evergreen shrub from Japan, name not known, to be seen again. Mr. Perry exhibited sixteen seedling Verbenas; two only received certificates. Messrs. Kelway sent nine seedling Gladioli, four of which were awarded certificates. J. Sladden, Esq., Ash, Kent, sent several seedling Gladioli. Messrs. Bunyard, Ashford, Kent, sent four seedling Gladioli—viz., Stella, Marguerite, Clipper, and Fawn, the latter novel in colour, but with no other recommendation. Mr. Jenks, gardener to D. Larnach, Esq., sent seedling Zonal Pelargonium Brambletye, a pale pink. Mr. C. Turner sent three seedling Dahlias—Mrs. T. Colman, Charles Lidgard, and Kensington, all of which were requested to be seen again. Mr. George, Putney Heath, exhibited Nosegay Pelargoniums Gem, Brightness, Northern Star, Minster, and Perfection.

The first prize for twenty-four spikes of Gladiolus was taken by Messrs. Kelway & Son, of Langport, Somerset, with very fine examples of Meyerbeer, Prince Imperial, Le Titien, Thomas Moore, Prince of Wales, Picciola, Sansparcil, Marie Dumortier, Accius, Gipsy Queen, Félicien David, Senator, Cherub, Picotee, Thomas Methven, Eurydice, Montaigne, Queen, Rossini, and Folton. The spikes in this collection were supported by brass rods placed lengthwise between the rows. The second prize was withheld, and the third awarded to Mr. J. Sladden, of Ash.

Class 2 was for twelve spikes. Here again Messrs. Kelway were first with a fine collection, in which, besides kinds already named, we noticed Emile, Molière, Apollon, Madame Desportes, a splendid new white variety; Freemason, which received a second-class certificate; Albert Victor, Flavia; Medina, which received a first-class certificate, in colour white tinged with lilac at the edges. The second prize was withheld, and the third awarded to Messrs. Bunyard & Son, of Maidstone.

Class 3 was for twelve spikes, and for amateurs only. Here Mr. Douglas, gardener to F. Whitbourn, Esq., Loxford Hall, was first with excellent spikes of Achille, Velleda, Princess Alice, Homère, Impératrice Eugénie, Madame Victor Verdier, Madame Furtado, Rossini, Madame Desportes, Adolphe Brongniart, Princess Mary of Cambridge, and Thomas Methven. The Rev. H. H. Dombrain was second, and Mr. Sladden third.

In Class 4, for six spikes, the Rev. H. H. Dombrain was first with Impératrice Eugénie, Milton, Madame Dombrain, Homère, Shakespeare, and Dr. Lindley. Mr. J. Sladden was second with seedling Crown of Gold, Monsieur Legouvé, Marie Dumortier, Dr. Lindley, and Thomas Methven. Mr. Douglas was third.

There was a good show of Hollyhocks. Mr. W. Chater and Messrs. J. J. Chater were respectively first and second for six cut spikes; and the same firms took the same relative positions for twenty-four cut blooms, Messrs. Kelway being third. For twelve the Rev. E. Hawke was first with beautiful examples of Ruby Queen, Willingham Model, Octavia, Phryne, Tournament, Alba superba, Ida, Caras Chater, Ivanhoe, Senior Wrangler, Acme, and Harold. Many of these are of Mr. Hawke's own raising, and the blooms exhibited were worthy of his high reputation as a raiser and grower of this flower.

Many complaints were made this day, and very justly made, that there was no accommodation in the way of tables on which exhibitors might arrange their flowers; it will be admitted it is not a pleasant thing to kneel on hard stones to arrange specimens of Gladioli and Hollyhocks, or any other cut specimens. This omission of preparing tables for putting up flowers must not be forgotten. The complaint made can easily be remedied; and when the Society is so well and kindly supported at these interesting meetings by amateurs and nurserymen, their request for this accommodation we feel sure will be in future complied with.

A meeting of the Committee was also held at Chiswick on the 10th inst., the Rev. J. Dix being in the chair. The Committee met in full force on this occasion, but the trial plants were far from being in a satisfactory condition; some of them were received very late in the season, others had suffered from the late frosts. The Committee propose shortly to hold another meeting at Chiswick, when the Zonal Pelargoniums will be in better condition. A few awards were made among the Bronze Zonal section. The Moor, Plutos, and the Rev. W. F. Radclyffe received first-class certificates. There is a great sameness in these Bronzes; as with the Tricolor Zonal, it is difficult to meet with anything new and distinct. Amy Richards, a seedling from the gardens, a robust Tricolor Zonal, received a first-class certificate as being of good constitution. Sir R. Napier, a distinct dark-zoned variety, also received a first-class certificate. There were many others the characters of which were not fully developed; they will probably receive rewards at the next meeting. Miss Kingsbury, a favourite Silver Bicolor, was in fine condition, and received a first-class certificate; and the same award was made to Beauty of Lee, a bright rose flower; Advancer, a deep rose flower; and William Underwood, a well-formed scarlet free-flowering variety, useful as a bedder.

The Committee was much pleased with a collection of Pentstemons, and among them with the light blue Pentstemon Jefferyanum. Owing to some confusion in the names no awards were made. These beautiful decorative plants are to be re-arranged for another season. It is much to be desired that the contributors of trial plants would send them earlier to the gardens, as in many instances justice cannot be done them. A collection of double Zonal Pelargoniums, under glass, met with much approbation. They had been well taken care of and neatly trained, and the plants were well covered with flowers.

General Meeting.—W. Wilson Saunders, Esq., F.R.S., in the chair. Two new Fellows were elected; one of them was H. Whitworth, Esq., the Secretary of the Manchester Botanic and Horticultural Society, in recognition of his assistance in connection with the Royal Horticultural Society's Manchester Show. The Committee awards having been reported, the Chairman, in the absence of the Rev. M. J. Berkeley, remarked on such of the plants as were of the greatest interest and beauty. Foremost among these was the magnificent specimen of Lilium auratum, from Mr. Goode, to which the Lindley medal was awarded. As this species of Lily had already exhibited a considerable tendency to produce variations in its markings, Mr. Saunders said he could not help thinking it offered a good basis for hybridisations, in order to add colour to its shape and fragrance. The collections of Gladiolus were next referred to as affording glorious colours, as well as the rapid rise of the flower in public favour. The Hollyhock, likewise, was touched on as exhibiting a charming diversity of colour, although when first introduced only a single flower, and it was recommended to anyone in want of a good effective plant for a border. Of the fine Amorphophallus, with a splendid snake-like-marked stem, shown by Mr. Bull, Mr. Saunders remarked that large as the head appeared, it consisted of but a single leaf. He had several species, and one closely allied to it, but not the same. They produced only one or two leaves. After pointing out the fine specimen of Lælia elegans Turneri, and Mr. Chater's dwarf Ageratum before alluded to, the latter of which he considered would be the admiration of thousands in bedding arrangements, Mr. Saunders passed on to the

climbing Asparagus from his own garden, and which had been sent home to him by a collector in his employ some years ago. Mr. Saunders stated that the plant grew to an enormous length, and he did not know what to do with it till he hit on the plan of growing it on cords tied to the rafter of the house, and which it soon runs up. One great advantage of this system of training was, that if desired, the plant could be moved from place to place by taking the cord down, which, with the plant, could be wound round the arm, but such was not the case when sticks or wire were employed. Many plants could be trained on cords; indeed, this was the best system for succulent climbers. Another plant, though not exhibited trained as a climber, but which in reality was a climbing Lily, being very closely allied to that family, and having been called Lilium gloriosum, was the Gloriosa from Mr. Clews. He thought all climbing plants should be exhibited trained as climbers; but perhaps he ought to make an exception of the Lapageria, of which Mr. Williams had sent a glorious specimen trained on wire, as it attained too large a size for exhibition in any other form.

SOIL FOR GRAPES.

I WISH to confirm the statement of your correspondent, "G. S.," in your Number of August 12th, page 124, by saying that my father possessed several vineyards at Vernone, near Turin, in Piedmont, planted on very calcareous soil. These vineyards were celebrated in the vicinity for fine crops of Grapes, producing superior wine; indeed, it commanded a higher price than neighbours around could obtain for their wines.—LEONARD HARMAN, JUN.

FINSBURY PARK.—We had always supposed that the design of the Finsbury Park was due to Mr. McKenzie who also designed the Alexandra Park; but having seen in the morning papers that Mr. Vulliamy claimed to have been the author of it, we were last week led to repeat his statement to that effect. We are since assured by Mr. McKenzie that to him alone the design of the park is attributable, and that the lodges, gates, fences, &c., belong to Mr. Vulliamy.

CUCUMBER CULTURE.—No. 8.

CULTURE IN POTS.—A very desirable method of growing Cucumbers for late autumn or early winter fruiting is in pots, as in this case they need no particular spot assigned them, but can be fruited in any house with the proper temperature. In pots, too, the plants generally fruit much earlier than those in borders, but they do not attain the same amount of strength, or continue so long in bearing. In spite of this, however, it is always a consideration to have a few fruits early; and if plants were not grown in pots they might not be grown at all for early fruiting, owing to want of room. Pot plants are more easy of accommodation than those planted-out, as the latter require both a border and plenty of space for their development.

Seeds sown in pots about the beginning of September will produce plants which will fruit in November; and for a succession it is best to sow on the 1st day of the month, and again on the 21st. If, however, a sowing was made at the beginning of September for planting-out, the second sowing in pots may be dispensed with, as the plants will bear at the same time; but if seeds be sown at the above two dates, sowing for planting-out may be deferred until the middle of October and 5th of November. Either of these plans will maintain a succession of fruit throughout the winter, spring, and summer; thus—1st of September sowing for November fruiting; 21st of September for January. Both of these sowings are for culture in pots. The 12th of October sowing is for fruiting about the end of February and on through the summer; but the early September sowing, one lot being potted and the other planted-out, will produce a like result.

The method of raising plants for pot culture does not differ from that pursued in raising those for planting-out. As regards the size of the pot, in a small pot we often obtain a much less development of foliage along with fruit equal to those produced in larger pots. I like a good-sized pot, and consider one 13 inches in diameter not too large. The drainage should occupy one-sixth of the depth of the pot, placing merely one crock over the hole, and for the remainder using lumps of charcoal free of dust. Some of the rougher parts of the soil should be placed over the drainage, both together occupying one-third of the depth of the pot. The plant is turned out with the ball entire into the centre of the pot, and the soil gently pressed round, space enough being left for surface-dressings. If bottom heat can be obtained, let the pots be plunged, or if there is a border let them stand on that rather than on a shelf or stage. Their position must be well exposed to the light, and they should be trained as near as possible to the glass, but without touching it. As the object is early fruiting, the plant should be stopped at least twice previous to being placed in the fruiting pot. It will show fruit before it has made a very long shoot, when it should be stopped one joint beyond the fruit. When there are two or three fruits, it will be well to keep each growth closely stopped to one joint, so as to have most of the foliage above the fruit. It is, however, desirable to retain a shoot near the base of the plant, so that when the fruits are cut from the upper part, the latter can be cut off down to the shoot at the base, which can be trained in its place, and will fruit even more freely than its predecessor.

As the plant advances it will put out roots near the surface, but should none appear after three weeks, I add about an inch of fresh soil every week until the pot be filled to the rim, and this will be sufficient to enable the plant to bear fruit large enough for cutting. The length is not a matter of so much consequence as the fruit being grown in a short time, and therefore crisp and free from bitterness; indeed, Cucumbers which are not of great length are generally the best in these respects.

When the first fruits are cut, some wait for the small ones to swell, which they often do, having a long shank-like neck, with a knob at the end, like a club. As these are worthless, I cut off the old foliage, and encourage the young shoot from the base. As we thus destroy the balance between the shoots or foliage and the roots, gangrene might ensue; but we remove the surface soil, picking out with a piece of wood as much as we can from amongst the roots and around the sides of the pot, and replace it with fresh. The soil is kept no more than moist until the foliage has progressed, and there is a greater demand for water; then all goes on as before. As we cannot top-dress without raising the soil above the rim of the pot, the latter is encircled with a rim of zinc, but I prefer myself one of turf, cut about 2 inches thick, and about 2¼ or 3 inches broad. The roots thrive in this, and rapidly pervade the soil, which is put on between the stem and rim of turf, becoming at length closely matted in the turf. This should be placed grass side downwards, and is in proper condition when it has lain until the grass is dead, the fibres being then in a nicely decomposed state, which, with air, is very beneficial to Cucumber roots. This top-dressing may be repeated as often as required, to secure the swelling of any fruit that may be upon the plant, but it may be discontinued after two or three have been swelled off, when the best plan is to start the plant again, cutting it down nearly to the base, and training young shoots in place of those cut away. The old top-dressing should be removed to the rim of the pot, and replaced with fresh, according to the growth. In this way the plants will continue in bearing for a long time, and in summer may be grown in houses, which can be kept sufficiently close and moist without injury to the other occupants; indeed, they will thrive in a cool house from May to October, and give finer fruit than in a heated structure if there is an abundance of light, and sun heat is husbanded by the early opening and closing of the house. A few plants may also be grown in a vinery when it is not convenient to devote a pit or house to their exclusive cultivation for the time. It is not necessary to employ the size of pot named, smaller will do. I have fruited Cucumbers in 7, 9, 11, 13, 15, and 18-inch pots; but for general purposes I like the 13-inch pot best—in fact, such a size of pot will afford nutriment for the swelling of two, three, or even more fruit per plant. I do not like to take more before cutting down or discarding the plants, as I advise when fruit can be obtained from those planted out in beds or borders.

When Cucumbers are grown in pots, the supply of water should be copious, not giving it in such quantity as to convert the soil into a saturated mass; do not let the soil become so dry as to cause the leaves to flag, but when water is required give enough to thoroughly moisten the soil. When it is necessary to increase the vigour of the plants or to swell the fruit, liquid manure may be given at every alternate watering.

For furnishing fruit in autumn and early winter it was formerly a practice to have the plants raised from cuttings in the last week of September or first week of October, and in the pots they are to be fruited in. For these 9-inch pots answer tolerably well, whilst 11-inch pots are equivalent to 13-inch pots for seedlings, as the cuttings do not grow so vigorously as plants from seeds. The pot may be prepared as described for the seedlings, and the cuttings inserted in the centre. Select for cuttings the growing points or tops of vigorous shoots; cut

them off 4 or 5 inches long below a joint, and remove the leaf, and so far up the shoot as will be inserted in the soil. Make a hole with a dibble, drop a pinch of sand into the hole, then introduce the cutting and fill up the hole with sand. Fine charcoal is better than sand. A piece of glass is placed over each pot, and the pots may be set in the places where the plants are to fruit. If due regard be paid to keeping the soil moist, the cuttings will be well rooted in a fortnight; then remove the pane of glass by degrees, and the plants will grow rapidly; soil being added, as roots push from the stem, until the pot is full. The fruit will be fit to cut before Christmas, when the plants may be cut down to the lowest joint, the surface soil removed, fresh added, and the plants in all respects treated as described for those from seed in pots. Plants from cuttings will endure a drier atmosphere, and are neither so succulent nor so liable to suffer from cold as seedlings; they will bear a temperature of 5° lower than seedlings and a drier atmosphere, and are not so liable to damp off, otherwise we do not see their advantage. By taking off cuttings at intervals the plants become, as it were, perennial. I know of one instance in which they were continued by cuttings successively for three years and a half, but then the deformity and uselessness of the fruit were abundant evidence that the natural limit to the existence of the plant had been exceeded.

As one, or at most two sorts of Cucumbers are enough to grow, I give the names of half a dozen which I have proved come up to the standard of merit—viz., "Length, not less than 12 inches; diameter, one-ninth of the length; colour, dark green; spines, black or white, and numerous; bloom, unremoved; circumference, circular and equal throughout; neck and nose, each not more than a diameter long; flesh, crisp and juicy; flower, remaining on the fruit."

For Winter and Early Use.	*For Summer.*

Telegraph (Rollisson's)	Hamilton's Needle Gun
The Coleshill	Dale's Conqueror

Those named for winter and early use are equally eligible for summer culture.—G. Abbey.

RENDLE'S PATENT PLANT PROTECTORS.

It is now hard upon thirty years since Mr. W. E. Rendle introduced "the tank system" of heating horticultural structures; and although the novelty of this cheap and efficient system has passed away, there are many who still adhere to it as in their estimation the best and most economical. That the tank system is the best for general purposes we are not prepared to allow; but if the advocates of bottom heat to Vine borders were to adopt it instead of iron pipes for their purpose, we

Fig. 1.

should not hear of so many failures in this practice of culture as we do. It is humid heat that Vine roots require, not a roasting. Let those, then, who wish to apply bottom heat to their Vines use the tank closed, with a perforated covering, and this with permeable material between the tank and the soil, and we shall be astonished if their efforts be not attended with success.

The same Mr. Rendle who rendered this service to horticulture in his earlier days, has now invented a mode of protecting

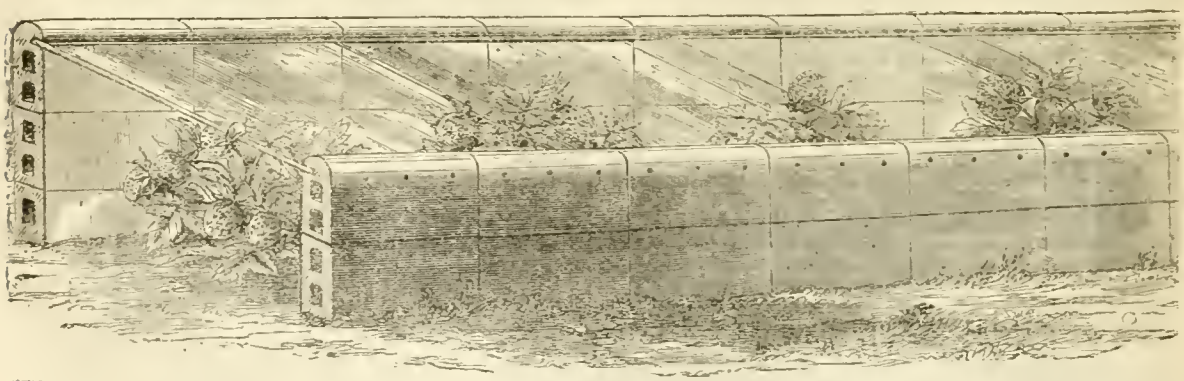

Fig. 2.

tender crops, which ought to obtain all the publicity and popularity which its merit demands. The contrivance consists in glazing, with Mr. Rendle's patent protecting bricks, low structures which may be called "frames" without the aid of putty, by merely slipping the sheets of glass into a grooved brick. We cannot better explain the principle than by referring our readers to the accompanying woodcuts. The length to which these little structures may be carried is limited only by the extent

of ground at command, and their width by the strength and length of the glass employed to glaze them. The uses of these structures are similar to those of the ground vineries, and although applied to the culture of the Vine, they are equally applicable to that of other crops, such as early Peas, and Salads; the propagation, by cuttings and grafting, of valuable plants in pots; and also for the protection of the less hardy plants during winter.

In *fig.* 1 we have the representation of a ground vinery. The drawing, which was supplied by Mr. Rendle, is not quite to our mind, as it represents the walls of the structure solid, whereas we would suggest that they be pigeon-holed so as to admit of that free circulation of air necessary in so small a space to ensure health and vigour to the plant enclosed. We have seen at Mr. Rivers's an experiment with these tiles erected after this fashion, and it succeeds admirably. The Vine is the picture of health and vigour, and under the glass there is the needful amount of humidity to secure health and keep down red spider. *Fig.* 2 shows its application to the protection and hastening of Strawberry crops. Here, too, we ought to have pigeon-holes. *Fig.* 3 represents a seed-protector—a protector from birds and from changes of temperature; and in *fig.* 4 we have the tiles used as a winter protection, by having them covered with any loose litter.

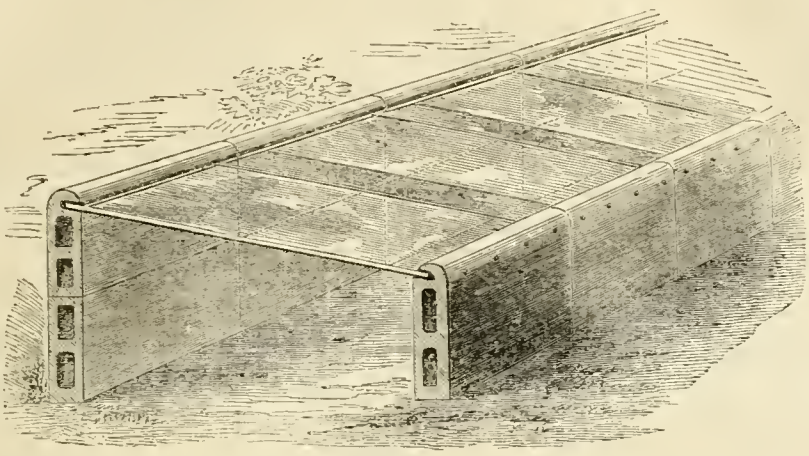

Fig. 3.

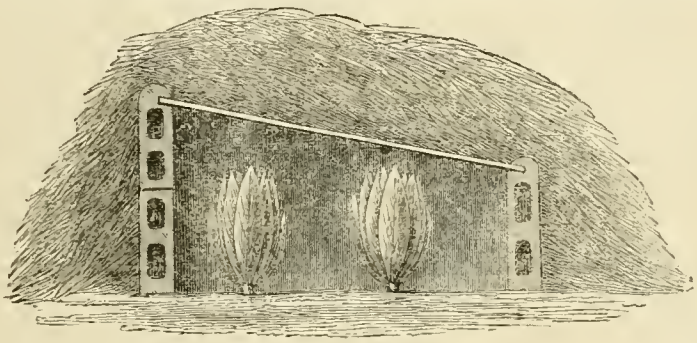

Fig. 4.

We would strongly urge Mr. Rendle to adopt the pigeon-holed principle. It is better for the general hardy use of the "protectors;" but it admits also of their being employed for forcing. When so employed heat may be applied by a lining of heating material placed all round them. As yet this is but the initiation of an idea which is capable of great development, and we see in it a fund of interest and usefulness in store for horticulturists. The great recommendations of this plan of Mr. Rendle's are cheapness, durability, disuse of putty and paint, and the total dispensation with the services of what are called "skilled workmen" in their erection. The material of which they are made is also an important element in the question, for the heat absorbed by bricks during the day will be given off at night, and in this respect bricks have the advantage over such structures made of wood and glass only.

LORD RAGLAN ROSE IN CANTERBURY, NEW ZEALAND—THE MAORIES.

I CANNOT refrain from sending word to such Rose-growers as the Rev. Mr. Radclyffe, Messrs. Paul, Messrs. Lane & Son, and to many other Rose-growers in the United Kingdom, a brief account of this Rose at the Antipodes. Its merits as regards flowering—Why, it is never out of flower here! Plant it where you like, and kick it about in any nook of your garden, flower it will at any time of the year. I feel quite delighted in sending you word that I gather a great number of hand-bouquets daily of this interesting Bourbon Rose, and everything bids fair for me to have a good supply during all the winter months out of doors. I often think of Mr. Radclyffe's good advice about Roses. It is this—"You had better grow fifty plants of a well-known good Rose than so many bad ones." To this effect he advises your ("our") troublesome correspondents to grow nothing but good Roses. He is right.

Général Jacqueminot is our next favourite here. I want a little more experience about the General here before I can write about him confidently. Try to convince the Rev. Mr. Radclyffe, through me, that his experience related in "our" Journal, meets with due honours here. Having read his list of the best Roses to grow, over and over again, it caused me to procure £10 worth of Roses from a firm in Melbourne, chiefly varieties recommended by him, and which have mostly been imported from the mother country. I will write you word about them from time to time. I shall always feel grateful for his advice in "our" Journal about Roses.

If I digress a little on this occasion, I hope you will pardon me, even for entering into colonial politics. I do not want the Rev. Mr. Radclyffe to think the Maories here do not understand the scent of a good Tea Rose. Quite the contrary. They do. The missionaries deceived them some few years ago, and now the poor fellows see Europeans occupying and settled on their original homesteads, obtained from them, as I shall presently state; it causes them to feel almost heart-broken in the northern island, and this explains why vengeance is sweet to them. All the outbreaks which are annually happening between us Europeans and them, simply arise from this fact. The missionaries gave them, in their ignorance of civilised laws, trinkets and toys for their homesteads and freeholds, if I may be allowed the use of the term. Hence all the bad news you hear from time to time in your English newspapers. The Maories, I can assure you, are a very fine race of intellectual men, no fools, since they have acquired European manners and customs. One thing I can vouch for, at any rate, they know a good Rose.

When the Duke of Edinburgh visited us this month (May), if you had seen their display of loyalty to Queen Victoria—excuse me, "WILTSHIRE RECTOR," for using your adopted name so freely in "our" Journal on this occasion, but something prompts my mind that yourself and our Rose-growing champion possess an abundant store of Christian fellow-feeling towards other races of men besides ourselves, and if your pulpits were here instead of at home, I feel you would say, Don't shoot these poor fellows yet, you Europeans; you know there is salvation in store for them as well as yourselves.

I will give you the purport of a very simple argument which

was tossed about in the crowd, when the Maories showed their faces to welcome the Prince. There were some fifty or sixty all mounted on horseback to the astonishment of us Europeans. Their good behaviour needs no comment. We settlers naturally asked ourselves, and argued the point together, Why should we Europeans here take advantage of a native race more ignorant, in some respects, than ourselves, and take from them all they possess? Common sense says it is wrong.

What I have written openly and candidly, are strong impressions on my mind about the indigenous race of human beings here.

Now I must have my say on this subject, as an old settler here. Our present provincial government have offered £1000 as a premium for the best system of preserving a certain quantity of meat in tins; £1000 ditto for the best manufacture of a quantity of woollen goods out of our own grown wool; £1000 ditto for the best sugar, a certain number of tons, manufactured from our own-grown Beetroot in Canterbury. This, I hope, will be a great inducement to capitalists to come out here. This is what we want, some money; population will follow. I will conclude by saying, that we pay now for a leg of mutton, 1*s.*; a whole sheep, 4*s.* 9*d.*; a whole lamb, 4*s.*; beef, 2*d.* to 7*d.* per lb. I am dining to-day (May 22nd), family included, on a prime cut from the sirloin, at 6*d.* per lb. We are perfectly glutted with butcher's meat here for want of population and capitalists.—William Swale.

RETARDING FRUIT TREES IN AN ORCHARD HOUSE.

My garden, consisting of about half an acre of garden ground, is surrounded by houses, and, therefore, in spring is very warm. In consequence of this warmth, early in spring my pot trees in a lean-to orchard house blossom much too soon, and invariably Peach and Nectarine trees bear no fruit. I have read attentively Mr. Kingsley's mode of piling the pots in the open air, and thus retarding the trees bursting into blossom. Do you think I might try it with any chance of success? Would the trees in pots now in the orchard house bear the same treatment?—H. F. Fry.

[You may safely retard your fruit trees in pots by keeping them out of doors, and protecting the pots and heads from severe frost. However warm your position is, you might retard the trees in the orchard house by giving plenty of air night and day, and dulling the glass with a little whitened water. With a free circulation, trees in an orchard house may be kept late in blossoming.]

TAUNTON DEANE FLORICULTURAL AND HORTICULTURAL SOCIETY.

This Society, which was established in 1866, held its fourth annual Exhibition on the 12th inst., and I have no hesitation in saying it was one of the very best exhibitions which ever took place out of London.

Some idea may be formed of the magnitude of the Exhibition, when I state that five large tents were filled with a varied and most excellent collection of flowers, fruits, and vegetables; a sixth tent was also partly filled with choice collections of hardy Ferns. The following are the dimensions of the tents:—No. 1, 46 by 36 yards; No. 2, 35 by 36; No. 3, 41 by 36; No. 4, 28 by 36; No. 5, 23 by 36; No. 6, 23 by 36. To have filled the above large space with such a magnificent collection as that I had the pleasure of seeing on Thursday is a great and lasting credit to the gardeners, amateurs, and cottagers residing in the neighbourhood of Taunton; it also augurs well the future of horticulture in Somerset, and shows that the spare hours of the gardener, the amateur, and the cottager are turned to good account, both in developing the beauties which deck our land, and in improving by superior cultivation what is sent for our sustenance. The man who could by constant care and watching produce such splendid results as those I allude to, be he cottager, amateur, or gardener, shows that he is possessed of something more than the ordinary amount of intelligence—he does not labour for gain; his is simply and purely a labour of love, which the owners of the soil not only in Somerset, but in every other county, would do well to encourage by every means in their power. This would greatly tend to lessen crime, and cause the benches of the alehouse to remain unoccupied, more than all the acts that could be passed in the best parliament that ever existed, or that ever will exist. The streets of Taunton on Thursday also presented such a scene as I have never before witnessed; business of all kinds seemed to be forgotten, and the whole town seemed to have but one thought—that of participating in the pleasure of witnessing and adding to the beauty and usefulness of the Exhibition. Every street, and I may almost say every house bore some testimony to the interest felt by the inhabitants in the proceedings of the day.

Now that we have entered the Show ground we must stroll quickly through the various tents, only stopping to notice the greatest rarities, or those commanding an extra share of notice, and even this will be a difficult matter, seeing that there were so few exhibitions which did not deserve the highest meed of praise that could be awarded. If, therefore, there are any that I have not noticed, it is not from want of inclination, but of time and space, for to mention all would take a considerable amount of both.

The whole of the tents were arranged alike, all having a centre stage or table, with a flanking table on each side, leaving ample space between the centre table or stage and the flanking tables for the public to pass comfortably through without damaging the exhibition subjects on either side. This is a hint that might be acted upon with advantage by some of the managers of our metropolitan exhibitions.

Tent No. 1 was set apart for the classes in which the principal prize collections were exhibited. These consisted of stove and greenhouse plants, ornamental-foliaged plants, and Ferns, which were shown in great abundance and in excellent condition. The first prize in the class for twelve stove and greenhouse plants was taken by J. B. Saunders, Esq., The Laurels, Taunton. This, like the collection that was awarded the second prize, consisted of a fine lot of plants. The preference was given to Mr. Saunders's collection in consequence of there being a greater number of flowering plants in it. In the first-prize collection were fine plants of Ixora coccinea superba, Phænocoma prolifera Barnesii finely bloomed, Allamanda nobilis, and Dipladenia crassinoda. The second-prize group contained a splendidly-bloomed plant of the pretty Lagerstræmia indica, so seldom met with in collections of the present day—a plant which should, however, have a place in every collection; a fine Allamanda Hendersoni; and the finest plant I have ever seen exhibited of Cassia corymbosa—another grand old plant not grown half so much as it ought to be. This I believe may be made one of our best early summer decorative plants by proper management. There was also shown in this collection the finest Maranta Veitchii ever exhibited; also a splendid Maranta roseo-picta. Both of these plants were shown in excellent condition. The collections to which the other prizes in this class were awarded, also contained many plants which, for high cultivation and general excellence, could scarcely be surpassed.

The class for twelve exotic Ferns was well contested, splendid plants being exhibited in each collection; here the beautiful and graceful Adiantum farleyense and A. scutum—Ferns put in commerce by Mr. Robert Veitch, of the Exeter Nurseries. Mr. R. Veitch also exhibited splendid specimens of these in a large collection of new and rare plants, which occupied a considerable portion of the centre stage. There was also a very choice collection of Ferns exhibited by J. Wilmot, Esq., of St. Thomas's, Exeter. In this collection was a noble Adiantum farleyense. In front of the plants I have just reviewed were placed on the ground pans of Lycopods in splendid condition. Mr. Williams, of Holloway, also occupied a large space on the centre stage with a collection of plants, among which I noticed an exceedingly fine Lapageria rosea, perhaps one of the finest plants that have ever been exhibited. Mr. Williams likewise exhibited a choice collection of new and rare plants. Fine groups of Fuchsias were also exhibited in this tent, and on the side tables Gladiolus, by Mr. Kelway, of Langport. Mr. Cypher, of Cheltenham, exhibited some very finely-grown stove, greenhouse, and ornamental-foliaged plants; so did Messrs. Dix and Nelson, the prizes being awarded in the order in which these names appear. There was, besides, a grand display of cut Verbenas shown on the side tables in this tent, as well as of cut Roses, Phloxes, Dahlias, and Zonal Pelargoniums. Cockscombs were well represented.

Tent No. 2 contained splendid collections of plants, chiefly contributed by amateurs and gentlemen's gardeners. In this tent I noticed some of the finest double Pelargoniums I ever remember having seen exhibited. I can only name a few of the gems amongst the many in this tent, such as Vinca oculata, splendidly bloomed; a nice pot of the pretty Coprosma Baueriana variegata, one of the coming bedding plants of the age; and the graceful Cupania Jacaranda, with its beautiful Fern-like leaves, undoubtedly one of the most beautiful plants we have for table decoration, and a worthy companion to the graceful Grevillea robusta. Standing on the ground in this tent I saw a large specimen of the curious Amorphophallus nobilis, with its handsomely mottled stems; this is, perhaps, one of the most remarkable plants we have for rapid growth, a few days only being required for it to mature its gigantic stem and foliage. There were also nice specimens of Terminalia elegans and Cossignea borbonica, two excellent plants for table decoration.

Tent No. 3 was much longer than the preceding two, and contained a fine collection of fruit and vegetables, arranged on a table extending the whole length of the tent. Dividing the fruit from the vegetables

was a row of Variegated and Bronze Zonal Pelargoniums. Amongst the fruit the magnificent Pines which were exhibited by Mr. Davies, gardener to Lord Bridport, were greatly admired and justly received the highest award. The grand display of vegetables which was arranged in this tent could only be appreciated by those who had the privilege of seeing it. I am well aware that the soil in the neighbourhood, and within a circuit of many miles round Taunton, is highly suitable for the growth of vegetables, but the soil alone could not have produced them of such quality; much praise is therefore due to the whole of the exhibitors in the several classes for the excellence of their productions, the worst of which were superior to many I have seen gain a first prize. At the top of this table Mr. Davies exhibited four splendid fruit of the Smooth-leaved Cayenne Pine Apple, not for competition. Other good Pine Apples were also exhibited, but not in classes for competition. There were numerous exhibitions of Cherries, Gooseberries, and Red and White Currants, but the display of the better class of fruits, such as Nectarines and Peaches, was small. For the latter, Mr. Davies took the first prize with a nice dish of Noblesse. There was a pretty good display of Melons, but not of very great merit.

Tent No. 4, like the previous one, was very spacious, and constituted the grand centre of attraction for the ladies, for it was there they were pitted against each other in friendly rivalry. There were displayed on the centre table the handiwork their fair fingers had wrought in the shape of numerous designs and devices for the decoration of the dinner-table, some of which were of a very elaborate character, others neat, simple, and, as I thought, in consequence much more appropriate for the purpose, too great a quantity of strongly-smelling flowers being in my opinion no way desirable. There was likewise a good display of bouquets and hanging-baskets of various sizes; also some handsome Fern vases neatly filled with Ferns and Mosses, and in the centre of the tent were displayed the prizes to be given to the successful competitors. In the various parts of the Exhibition, on the side tables, large quantities of cut Roses, Asters, and various other florists' flowers were exhibited, besides a large collection of Gourds, Vegetable Marrows, &c.

Near the entrance to this tent a very interesting collection of British wild flowers was exhibited in a style unsurpassed by anything of the kind I have ever seen. The system of their arrangement was unique. There were 144 specimens botanically described. The manner in which this collection was staged reflects the highest credit on those who had the task of bringing them together and exhibiting them. The collection contained many gems of great beauty and interest.

Tent No. 5 was termed the cottagers' tent. In this a very excellent assortment of vegetables and flowers was displayed; the vegetables being equal in quality and quantity to those exhibited by the professional gardeners and by the amateurs. Their nosegays were also pretty, and in many instances very judiciously arranged. One of the most successful exhibitors in this tent was a man named Daw, who is a railway guard on the Taunton and Chard Railway. He took, I think, about fourteen prizes, ten of which were first prizes; his productions were of great excellence, and much credit is due to him, as I understand the ground where he grew these fine specimens of vegetables was, three years ago, of the poorest character, and to all appearance quite unfit for the cultivation of vegetables or anything else; but by the constant application of the spade, and sweeping the roads for manure, he has brought it to its present fertile state. I had an opportunity of seeing a handsome watch which had been presented to him for his general carefulness and kindness by the passengers travelling over the line. This is the sort of man we want to entrust our lives to, careful in small matters, and worthy the charge of great. At the entrance of this tent a very pretty model of a flower garden was exhibited. This was a very skilful and prettily arranged model, showing a good taste in design, and also in the arrangement of colours.

In tent No. 6 a very fine collection of hardy British Ferns was exhibited. This brings me to the end of my journey through the tents. Although several of them, as above stated, were crammed, there were several vanloads of plants sent away from the ground unpacked in consequence of there not being time for their arrangement before the Judges commenced their labours. I must speak in terms of the highest praise of the admirable manner in which the whole of the arrangements connected with the Exhibition were carried out by J. B. Saunders, Esq., and the Committee who so ably and agreeably acted with him for the good of the Society and the development of horticulture generally in the neighbourhood; also of the excellence of the plants exhibited by Mr. Saunders, Mr. Marshall, Mr. Taylor, Mr. Hellard, and other gentlemen in the neighbourhood, whose names for the moment I do not remember. It must be a source of great gratification to them, that by the means at their command, and the talent and energy of their gardeners, they have been able to present such a horticultural spectacle as has never before been witnessed in the west of England, and which if carried out next next year in connection with the Show of the Bath and West of England and Southern Counties Association, which is to be held at Taunton next July, must, with the assistance of exhibitors from other parts of the country, prove a still greater success.

Among the decorations of the town I must notice the magnificent arch erected by Mr. Dyer over the North Street, in front of his establishment. It was certainly one of the handsomest I have ever seen, reflecting the highest credit on the skill of Mr. G. Stevens, who was the designer, and on Mr. Dyer who so ably carried out the work. To this the first prize was awarded.

I append the list of awards to this report, which has fallen very far short of conveying an adequate idea of the excellence of the Exhibition, which I am glad to hear has considerably augmented the funds of the Society, enabling them to offer more numerous and better prizes another year.

In consequence of the number of exhibitions, many stands were passed over unnoticed by the Judges. In future, exhibitors should be careful to see their specimens properly placed before leaving the tent. A fine Orchid from the garden of J. Marshall, Esq., was passed over in this way.—J. Wills, F.R.H.S.

HONEY.—The largest quantity taken during the season from one swarm.—1, Mr. T. Shattock. Best box or glass, 1869.—1, Mr. T. Shattock.

JUDGES.—*Plants and Flowers*:—Mr. Turner, Slough; Mr. Dean, Ealing; and Mr. T. Parker, of Bristol. *Fruit*:—Mr. Cramb, gardener to the Earl of Ducie, Tortworth Court; and Mr. Clarke, gardener to Mrs. Esdaile, Cothelstone House. *Vegetables*:—Mr. Megin; Mr. M'Culloch, gardener to Sir A. A. Hood, St. Audries; and Mr. Saul, gardener to Dr. Woodforde. *Cottagers' Fruit and Vegetables*:—Messrs. J. H. Horsey, Taunton; Mr. Davis, gardener to Lord Bridport; and R. Huxtable, gardener to Mr. F. W. Newton, Barton Grange.

WORK FOR THE WEEK.

KITCHEN GARDEN.

STIR the surface of the soil deeply amongst growing crops to admit air to the roots, and to keep down weeds. Take advantage of dry days to earth-up *Celery*, first thoroughly soaking the rows with manure water; also apply quicklime when slugs are troublesome. On heavy soils it is sometimes necessary to surround the plants with sand or sifted ashes to prevent their decaying in winter, which they are apt to do if surrounded with a very moist soil. Where this treatment is necessary it will be advisable to defer earthing-up till late in the season, as frequent soilings of this kind will be very troublesome. Also, pull up early *Onions* where ripe, and thoroughly dry them. *Potatoes* in wet soils should be taken up whenever the haulm is at all decayed, to prevent them from rotting. Thin young crops of *Spinach*, *Turnips*, &c., before they become weakly and drawn.

FRUIT GARDEN.

Any of the Peach and Nectarine trees which are observed to be growing too freely should be gone over, and all the stronger shoots stopped; and those that were treated in this way a few weeks ago should also be looked over again, stopping a further portion of the shoots if necessary, to prevent the formation of gross strong wood. Pear, and indeed all trained fruit trees, should also be examined, removing all superfluous wood, so as to expose the trees to sun and air as fully as possible. This will promote the ripening of the fruit spurs and bearing wood before winter. Recently-planted Strawberries will be benefited by occasional applications of manure water. Let ground be manured and dug, or trenched, for another crop, whenever time can be spared for this kind of work. Crevices between the soil and walls are the favourite resorts of numerous insects; therefore at this season, the soil adjoining walls should be frequently disturbed. A shallow trench may be taken out all along, and as this is being proceeded with, the soil adhering to the bricks should be removed with a hand broom. The portion of wall thus exposed should be sprinkled with gas water, or lime water if the former cannot be readily obtained. Lime water should be applied the instant it is made.

FLOWER GARDEN.

In addition to cuttings, keep a reserve stock of strong plants in pots, which is a safe practice where a large quantity of bedding material is required, and where there is proper convenience for growing and propagating in spring. These will furnish a large quantity of cuttings next March, which will form equally good plants by turning-out time as cuttings put in now. In the case of such plants as Ageratums, Heliotropes, and dwarf Lobelias, it is useless wintering young stock, for they grow so freely in heat, and are so easily propagated from soft cuttings, that a few good-sized old plants which require but little room or attention in winter, will furnish a very large quantity by turning-out time. See, however, where there are not plants to furnish spring cuttings, that plenty of cuttings are now put in, so as to provide, while it can be done, against running short of stock at planting-out time. Roses may be propagated by cuttings; choose the ends of shoots with the bottom part in a tolerably firm state. Let ground intended to be planted with young stock from the nursery be turned-up as soon as possible, especially in the case of strong adhesive soils, which are quite unfit for planting until they have been exposed to mellowing influences for some considerable time. Look over rock plants, pruning-back any that are overgrowing choice kinds, in order to give them sufficient time to break again. Cuttings of choice kinds should now be put in for planting out in spring. Peg down a few shoots of Chrysanthemums for layering in pots; this is better effected after the shoot has turned up at the point. Cut out some of the leaves from Hollyhocks to show their bloom. Polyanthuses may be parted, but use the knife as little as possible in the operation. Prick out seedling Auriculas into store pots or pans, so that they may become well-established before winter. Seedling bulbs of Tulips which have been out of the ground since the tops decayed, should be reset; for if kept out long the smallest are apt to perish. Many of the Carnations and Picotees that were layered early will now be fit to take off; it is better to detach them from the parent plant as soon as rooted. Continue to look to your seed-pods, sheltering them from excessive wet, and extracting decayed petals. Layering may be continued, though it will depend on the attention bestowed afterwards whether they will root well. Prick-out seedling Pansies, and plant-out the first-struck cuttings for next year's bloom. Pull off all damaged or deformed flowers, and take especial care by constant attention to staking and tying that the plants are not broken during boisterous weather.

GREENHOUSE AND CONSERVATORY.

Preparations must soon be made for bringing tender plants out of doors under cover. Where there is proper accommodation for these under glass, there can be no use in keeping them out of doors late this autumn; but in cases where they have to be wintered in vineries, it is often necessary to make every possible shift to keep them out of doors until the state of the Vines, &c., allows the houses to be managed with something like regard to the well-being of the plants. With the aid of tiffany houses or skeleton frames or pits, constructed so that they will ward off a few degrees of frost, and a waterproof cloth, old sashes, or anything for covering that will throw off heavy rains, most greenhouse plants may be kept safely enough out of doors for some time yet, unless the weather should prove more unfavourable than it is. They will be found also to do much better under such shelter than crowded together too thickly in houses where fire heat must be used. Indeed, when plants have to be wintered in forcing houses and other places which are not always in a fit state for their reception at the proper time, some temporary shelter is indispensable to shelter the plants from the drenching rains and cold winds of autumn, and a very suitable one would cost but little and would be found useful at most seasons. Luculias and other winter-flowering plants growing in the borders of the conservatory must be freely exposed to light and air, in order to ripen the growth well, and insure a fine display of bloom. Also see that all plants are clear of thrips, for this pest is particularly active now wherever it is allowed to obtain a hold, especially on Luculias and plants in a growing state.

STOVE.

Where there is but one stove for the accommodation of tropical plants, considerable care and attention are necessary to manage these properly at this season, as some, having completed their season's growth, require to be kept cool and rather dry in order to ripen the wood; while others in free growth require to be encouraged with warmth and moisture. If there is no convenience for removing to a cooler house plants which have made their growth, these should be placed together at one end of the house, keeping them sparingly supplied with water at the root, and giving air rather freely, which will generally serve to prevent any attempt at a second growth. Those requiring to be kept warm and moist should also be placed together at the opposite end of the house, where very little air should be given, using every care to keep the atmosphere about them moist. Allamandas and Clerodendrons which have finished blooming, may be removed to a vinery, where Grapes are ripe or ripening; for as they will require very little water, they will not do much mischief in the way of causing damp, and their room will be found very useful for other plants. See that everything is free from insects, and keep the foliage of

such plants as Ixoras, &c., clean, by washing with a sponge and soapy water when necessary.—W. Keane.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

The frequent showers made us anxious to plant ground on which the crops were nearly over. We removed our third and fourth lots of Peas, and filled the ground with Broccoli and other vegetables for winter. Here we find the mixed system of planting and close-cropping rather advantageous. The Peas were grown in rows 6 feet apart, but there was a row of Broad Beans between every two rows of Peas, and the ground was carpeted besides with Radishes, Spinach, or Lettuces. We rather regretted moving off the Spinach, but we were forced to think of the future. The Beans are still strong and good, and those now 6 feet apart will give a little shade and protection to the Broccoli, &c. Each of the 6-feet spaces held three rows of vegetables; and as the ground had been heavily cropped, we gave each space a fair supply of the best material from the rubbish heap. Being short of room, we have a good breadth of Leeks outside the walls in a place broken up on purpose, as we have noticed in the course of years that hares and rabbits never interfered with our Leeks when we had to net, and secured them from everything else. In some cases where the Broccoli and Borecoles had become a little leggy, we used the crowbar in planting, as when firmly fixed, such plants do not dislike firm soil. In planting banks of Cauliflower in rows about 24 inches apart we have planted Cos *Lettuces* between, as they will be off before the Cauliflower fill the space. Planted out Lettuces of all kinds in every open space, and we have still two successions, which will carry us on to the beginning of winter, and through the winter if we put them under glass. Our last sowing to stand the winter will be made in a few days, and for this sowing we prefer that the ground should be rather poor, and just stirred at the surface —not forked, nor dug deeply. The seeds should be sown rather thickly, so that the plants shall protect each other when up, and merely patted down and covered with a little light soil. Favourite kinds of Lettuce seed must now be saved from the birds when ripening, otherwise they will soon clear it all off. Such seed is often easiest preserved in village gardens, as there the boys and girls keep the birds at bay.

A little *Endive* may still be sown in ridged borders or on the tops of ridges, and if the winter be at all favourable, the plants will prove useful in spring before the first spring Lettuces. Planted out lots of Fraser's Broad-leaved Batavian and the Curled Endive at the foot of walls to stand the winter, and on flat ground for earlier use. Where the seedlings are crowded, it is as well to take off the points of the longest leaves before planting, as they will be sure to flag, and thus retard free rooting. When sown thinly, so that the seedlings will have more room, this barbarous method of cutting off the leaves will not be necessary. We often err in thick seed beds merely to save room. The less the leaves are interfered with the sooner will a strong plant be formed, if these leaves can be kept fresh.

We lately planted a border of Cauliflower that had been previously pricked out, lifting the plants with balls, and at the same time planted a bank from a seed bed, the plants being to all appearance quite as good, and about the same age; but the pricked-out ones have scarcely shown a single flagged leaf, and will come in a fortnight or three weeks before the others that received no such care and preparation. Stout plants of Cauliflower turned out now in rich soil well pulverised, will make fine growth before the dark days, more especially if some protection can be given, or the most forward can be cut and treated as detailed lately. The Walcheren Cauliflower or Broccoli so treated will be hardier, and Snow's Broccoli should now be looked after, as it is so useful in the first part of winter. Our first sowing of Cauliflower is just breaking the soil, and we shall sow again in a few days.

We have made two sowings of Winter Spinach, and will follow with another in a few days. We cannot afford large breadths of this useful vegetable, and we find it safest to sow at several times, as if the first-sown plants become too strong they do not pass the winter so well as those not quite so succulent. We sowed the Spinach in rows 15 inches apart, and Radishes in the space between, the Radish seed being red-leaded to keep the birds from them. All the Radishes will be gone before the Spinach wants the space. We sowed Silver-skinned and other Onions for salading, as when used very young, many are required. Some people will have them not larger than needles, smaller by far than Chives, and in such a case there must be plenty of seed and plenty of sowings. We shall put in our first sowing of Tripoli in a few days, and will follow with another in eight or ten days, for like the Spinach, in a very mild winter the first sowing will not bulb so early and so well as in spring as the late sowings.

All early *Potatoes* where the haulm is becoming ripe and showing decay, will be better out of the ground than in it, and the space will then be at liberty. For small gardens hardly anything will exceed in productiveness the Prolific Ash-leaved Kidney, and it makes so little head that the rows may be pretty close. Our crops for some years have been wonderful. When to be kept for use, the tubers should be covered over with soil, and it is a good plan to size the tubers at storing time. We have tried numerous sorts of Potatoes, and fine kinds for produce and for flavour, but many of them instead of giving us haulm from 12 to 18 inches in length like the Prolific, give us shoots in our stony soil from 3 feet and upwards. Of course, such kinds require a great deal more room to give them justice. Provided fine-flavoured good-sized tubers can be obtained in plenty, the smaller the tops the better is the kind for small gardens. Besides there is less danger of disease if the sun can shine on each side of the row, than when the whole space seems a tangled mass of shoots and leaves; and the recumbent stems in moist weather are hardly ever dry. One reason why all ripe Potatoes should be lifted is, that if we have rainy weather the tubers will begin to grow again, and that greatly impairs their nourishing and agreeable qualities. Several circumstances have brought prominently before our notice this season, that to produce fine-flavoured Potatoes, good soil which has been well exposed to the air should be used, but no dung, unless well rotted and sweetened beforehand. Rank manure if it cause the production of good crops will cause rankness of flavour. Several samples that came under our notice showed but too well what they had been dunged with. The glory of a Potato is to be free from all peculiar flavour.

We took up the last of our large Onions which stood the winter, and set them with their roots upwards in a sunny place, with some old lights over them to keep them dry. The spring-sown ones are swelling well now. As we shall not have them off soon enough, we shall prick-out the most forward Cabbages, and lift these with balls afterwards. We shall sow a few Cabbages to stand the winter in the bed. Our second Cabbages are peeping through the soil. We sowed a piece of Turnips, and shall sow again in eight days, as they become useful in winter and spring.

FRUIT GARDEN.

Almost finished shortening shoots of trees, and will do the same with Currants and Gooseberries as soon as possible, so that we may find more room between them for sticking out winter stuff, as all becomes useful then, and can easily be removed in the spring if not wanted. All very strong shoots of Peaches and Nectarines should either be removed or shortened back, as very strong shoots will not be fruitful themselves, and will rob others of due strength. Protected Currants and Gooseberries by netting, &c. We have not done much with matting-up, &c., of late, and we think free bottling is almost as good, if not better for tarts; and unless Currants are well crystallised with sugar, but few people care for them at the dessert table.

We have not been able to clear our Strawberry beds of runners, &c., and are not particularly careful just now, as we have no dung short and rotten enough to place between the rows. We shall prick off a good many runners thickly, and they will be useful if wanted. See what was said of potting for forcing. A plant with a strong central bud, well ripened, will be more to be depended on than one with two or three smaller buds. Some kinds, however, often break into two or three buds, and when old plants are pressed into service these will generally have more than one bud. Plants intended for forcing must never be dry until their work is finished in the autumn, and even then the soil though not wet, should be moist rather than dry. When pots are kept under glass or other protection in winter, the flower-buds, in their incipient state, have often been ruined, by being dried up and shrivelled. From a contrary cause, after a little heat is given in the first stages of forcing, the buds are often flooded up, and rot and decay, in consequence of too much moisture. At that time before the truss appears, the soil should not be too wet, and the top of the soil should be sailed with the moisture without wetting the buds or crowns. Success often depends on such minor points of management.

Banked up frames in which Cucumbers and Melons are growing, as the heat was beginning to decline. In such dripping weather, a rough spout of some sort in front of a frame is of importance, as it prevents the wet soaking into and cooling the bed. We gave a little heat during the wet days to the vineries and Fig houses, &c., so as to keep the air in active motion, and prevent the temperature falling too low. Grapes well ripened in September will keep longer than those ripened later. Gave a good syringing to the first Peach house, and left the lights off for the rains. In orchard house, syringed little where the fruit is ripening. Top-dressed the pots, as it saves watering, using chiefly rotten dung, with a little soot. Where Pine Apples are grown, now is a good time for putting the earliest fruiters for next year into their fruiting pots.

Looking-glasses for Birds.—In relation to what was stated in a late number as to these deterrents for birds from seeds and fruit, a sample of two has been kindly sent us through the Editors from Mr. Peter Selby, 15½, Newhall Hill, Birmingham, and having suspended them over a piece of seeds, we have noticed the birds fly past them, and as yet no scratch appears in or on the ground. We mean to procure a few, and give them a farther trial, as the expense will be small. These small glasses are very neat, having black iron backs, and neat brass-gilt frames in front. The frames and glasses are oval; the greatest length of the frame is nearly 4 inches, and the greatest width about 3¼ inches. The long and short diameters of the looking-glass are about 2¼ by 1⅞ inches. Mr. Selby, who is an old subscriber, and thus noticed our inquiry, offers these mirrors at a very low rate. Where birds are plentiful and mischievous they well deserve a trial, and we trust they will render the sound of the gun unnecessary. Farther experience will be wanted as to their continued utility in this direction, as birds, animals, and children too, become used to such deterrents. Many years ago we used broken pieces of mirrors with good effect; but the little mirrors above referred to are much more neat and handy, and are easily hung on a string at once.

ORNAMENTAL DEPARTMENT.

Attended to the routine of mowing, sweeping, and rolling the lawns and walks. The rains having softened the lawn, we dug or spudded up a large number of the broad-leaved Plantains, which threatened to occupy some turf put over beds two years ago. The turf was taken from the sides of the lanes and highways. On most of such turf, though not a trace of a Plantain may have been left at turfing time, it will often be years before one gets rid of them, as so many seeds are imbedded in the turf, and need free access to air, to germinate. Few things mar the appearance of a lawn more, and if let alone, a single strong plant would soon require some feet for itself and its progeny, as the side shoots grow rapidly. In comparison with these, Daisies are a trifle, as unless very thick, the grass pretty well overtops them by this time. The Plantain, on the other hand, mars the look of the best-kept lawn. We noticed lately a cloud of Thistle down careering over our lawn, and dread them finding a resting place there.

As respects the *Plantain*, and other large succulent-leaved plants, we had a cask of prepared sand sent to us, price about 30*s.* per cwt., that was to do wonders, kill all the Plantains, Daisies, &c., and invigorate the grass at the same time. It so far answered that it did no harm to the grass, and applied to Plantains, a pinch between the thumb and two fingers to a good-sized plant, it soon shrivelled up the foliage, and seemed to kill the long root for a good distance, and a broom was only required to sweep up the black and shrivelled tops. Now, however, we perceive we are little or nothing the better, as the Plantains are appearing from the lower part of the roots again. We considered, therefore, that where time could be given, rooting-up was on the whole the most economical mode of destruction. This requires care, and a strong iron, best with a suitable handle, as cutting them up, or merely breaking or cutting the root a few inches below the surface, is but a very temporary relief, as in a few weeks you will have two or three shoots or broad Plantain heads instead of one. Care should be taken that the plant should be raised close to, or even with the extremity of the roots. We have measured many of these roots from 12 to 20 inches in length, and we know that if only a few inches next the surface of roots like these be removed, the plants will soon assert room for themselves.

The worst of taking up large roots at this season is that for a time there will be an empty spot on the grass, and before the grass grows over, that space will be below the level of the surrounding lawn. To lessen the continuance of this appearance, when we uproot many Plantains we scatter a few seeds of White Dutch Clover over the space, and when that is damped with a shower or dew we scatter over the seeds a little finely sifted soil, so as to make the spaces more level with the lawn, and then when the lawn is dry roll well over. A few fine Bents may be added with the Clover. A green surface is thus soon attained, and a little of this Clover is very soft. We regret we could not speak more enthusiastically of this chemically prepared sand, as it would otherwise be very suitable for small lawns, where a little first outlay would be more pleasant than spudding up weeds. Probably if used more freely than we did, it would be more destructive to all succulent-leaved plants. We find it did no injury to the grass plants even if sown broadcast—quite the reverse, but it killed the foliage of Daisies and Plantains.

The rains have washed off so many of the Calceolaria flowers, that we have had to grass over the beds, nipping off partially denuded trusses to give more room and strength to those coming on. We have also had to take away a few leaves from the scarlet Pelargoniums, as they are now quite luxuriant enough. Edgings also needed a little regulating. Grass mice are troublesome in raised beds where Verbenas are growing.

Made preparations by collecting fresh soil for propagating, and will commence with all flower-garden plants presently. The less artificial heat they all receive the better. Verbenas, Petunias, &c., we shall place in a cool pit; Pelargoniums chiefly in the open air. Much depends on sweet fresh soil, a little light rather than heavy. Cuttings that strike often do badly in winter from using old sour soil for the pots and boxes. If we give any manure at all, it is generally a little sweet dung or leaf mould at the bottom of the pots or boxes.

Pricked-out and potted according to age and size, plants of Primula sinensis; grew on double ones in a pit; potted Coleuses for autumn work, and put in cuttings to stand the winter, in little room. Potted Cinerarias, sowed Calceolarias, and cut down more Pelargoniums of sorts; the first cut down are now ready for repotting. Most of the soil will be shaken away, the roots trimmed a little, and put carefully in smaller pots, in light sandy soil, and kept shaded for a little until the roots are working freely in the fresh soil. Put Camellias in a shady place out of doors; Epacris and winter-flowering Heaths should now be in pits with glass, to defend them from showers, but with air back and front night and day, but fully exposed to the sun to ripen the wood. Sowed Mignonette and some annuals for the winter, proceeded with potting Ferns, and all plants requiring that treatment, and moving plants in the flower houses as often as they showed signs of distress, bringing in others to replace them.—R. F.

COVENT GARDEN MARKET.—August 18.

The market has been very unsteady, the chief attendance of buyers being on Saturday, rendering things of more value on one day than another. Supplies are ample, and foreign importations heavy. Shippers from the Channel Islands are also large senders.

FRUIT.

TRADE CATALOGUES RECEIVED.

William Dillistone, Sible Hedingham, Essex.—*Catalogue of Choice New Plants, and Dutch and other Bulbs, &c.*

Giles & Pascoe, Grove Hill Nursery, Third Creek, and 12, Hindley Street, Adelaide, South Australia.—*General Catalogue of Trees, Plants, Shrubs, &c.*

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely to The Editors of the Journal of Horticulture, &c.*, 171, *Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

Books (*A Learner*).—Two books will supply all the information you name. McIntosh's "Book of the Garden," and Stephens's "Book of the Farm." (*R.*).—Johnson's "Cottage Gardeners' Dictionary" contains the information you need.

Black Cluster Grapes (*A Constant Reader*).—Not knowing where they are grown nor your mode of culture, we cannot give an opinion as to the cause. See what we said last week about Sweetwater Grapes cracking.

Bedding Pelargonium (*W. Ashwell*).—There are now many varieties with leaves exactly like that you enclosed.

Caterpillars on Cherry Tree Leaves (*Linda*).—They are the slimy grub, the larvæ of the Selandria Æthiops, a species of saw fly. Dust the powder of fresh quicklime over them.

Lists of Flowers (*A Lover of Good Things*).—We always give the names of both species and varieties of all flowers and plants which we know to be good as well as new.

Poppies (*G. Mc.F.*).—The seed vessels of all Poppies contain opium, but there is none in their seeds. The Deadly Nightshade is one of the Natural Order Solanaceæ, totally distinct from the Umbelliferæ in which the Carrot is included.

Pelargonium Cuttings (*H. S.*).—They may be wintered very safely in your bow window; but you must exclude frost from them.

Seedling Scarlet Pelargonium (*I. L. D.*).—The petals had all fallen off; as far as colour and size of truss are concerned, it has no superiority over other varieties.

Do Birds Eat Alpine Strawberries? (*H.*).—Mr. Middleton mentions, as you perceive, a peculiar Alpine Strawberry. We know the birds taste the common Alpine, but we know they will never look at them when finer Strawberries are to be had. We have no doubt our correspondent will tell all he knows himself.

Succession of Strawberries (*Rev. E. H.*).—Knight's Princess of Wales, Vicomtesse Héricart de Thury, Sir Charles Napier, and Dr. Hogg.

Vicomtesse Héricart na Thury Strawberry (*J. B. D., Bitteswell*).—It was advertised in our number for August 5th.

Flower-bed Arrangement (*Banks of the Thames*).—We think you will like the planting of your beds as proposed. There are two things that strike us—the large beds, No. 1 and No. 8, will look well with the outside band of Mangles's Pelargonium and the double band of Stella, but we do not think that Alternanthus melancholicus will make a telling centre for Stella. As you seem to have no yellow on that side of the garden we should have a strong yellow Calceolaria, as Salviæfolia or Aurantia multiflora for the centre, and then you need not have yellow in 9, 9, but in II, 11. This would lighten up the colours better; and then we would like to edge all the beds. For instance, 3, 3, would be greatly benefited by a skirting of Purple King Verbena.

Grapes Swelling Irregularly (*A. Dumbell*).—It is difficult to say what is making the Vines swell their bunches irregularly. It is just possible that they wanted more nourishment. If you mean these Vines in pots to do any good next season they must not bear above three or four bunches this season, the foliage must have free access to the sun, and everything must be done by feeding to have the wood good and well ripened, leaving no more side shoots than the plant will sustain, and cutting these back to a bud or two when the leaves fall. As to the Vines planted, we should be inclined to cut them back to 2 or 3 feet after the leaves fall, encouraging growth all the summer; for a little sacrifice now the Vines will make amends afterwards. The Vines in pots we would not repot, but remove the surface for 2 or 3 inches in autumn, and fill up with rich compost.

Vines Newly Planted (*H. B.*).—The Vines will grow vigorously for some weeks yet, especially those planted in May, and we should advise your continuing to grow them on for a month or six weeks longer, and then secure the ripening of the wood by keeping them drier both at the roots and in the atmosphere, with a little fire by day and abundance of air. At this season you will not require fire heat. An abundance of air should be given. For such high front lights as yours appear to be, we should prefer their opening as casements, certainly not up and down like windows, or if they are they should be double-hung, both upper and lower parts moving.

Lady Downe's Grapes Spotted (*H. H.*).—The Lady Downe's is not more liable to spot than many other Grapes. The spot is anything but a new disease, being occasioned by an insufficient supply of sap. The roots being in a colder medium than the branches, the foliage exposed to very powerful sun, and the evaporation excessive, the supply of sap is not equal to the demand. The upper portions of the bunches are most liable to suffer, and invariably first, which shows that the same influence on the berries scalds them; therefore, care should be taken to have the bunches well protected by the shade of the foliage, and when this is the case spotting is seldom known. It prevents the roots becoming so inactive as they do when the foliage is scant; and the supply of sap is more regular, and its circulation not so liable to become inactive in case of undue moisture from excessive watering, or heavy rains. The grafting on the Red or Grizzly Frontignan would tend to cause the spot on the Lady Downe's, as the Frontignan is notorious for shanking—twin sister to the spot.—G. A.

Annuals for Autumn Sowing (*An Amateur*).—The Virginian Stock (Malcomia maritima), is the nearest approach to purple that we know of in a plant having the semi-prostrate habit of Saponaria calabrica. Purple Candytuft makes a splendid mass, but is of stiff erect habit, but if the plants are not allowed to grow too close together they branch well and close to the ground. Limnanthes Douglasii is the best yellowish-flowering annual for autumn sowing, and Eschscholtzia crocea is also good, but not equal to the Limnanthes, though a far better yellow.

Plant (*G. B.*).—We think the sprig is from a plant of the genus Echium, but which we could not say without a better specimen and leaves. Specimens should be sent packed in damp moss. It is probably a biennial. The seed should be saved and may be sown as soon as ripe in a bed of sandy soil enriched with leaf mould, or in April, the young plants being thinned out to 1 foot apart. Bees are very partial to all the Borageworts; a large bed of Borage ought to be in every garden where bees are kept. The old plants may be taken up from the walk and planted in sandy soil after the flowering is over and the seed ripe, for it may prove a perennial, but we think not.

Scale on Otaheite Orange (*De Foix*).—The black fungus is the result of honeydew, occasioned by a smallish insect you will find closely fixed along the sides of the midribs underneath the leaves. Remove that and the fungus will disappear. After dipping the plants in water at a temperature of 120° for a minute, the leaves should be washed on both sides with a sponge, employing soft soap, 4 ozs. to the gallon of water. Clarke's Compound, Fowler's Insecticide, and Gishurst Compound are good remedies if used as a wash, or for dipping the plants in. Orange fungus on Roses may be destroyed by forcible syringings and copious waterings.

Combe Abbey.—In the eleventh line from the beginning of the account of this place, page 126, first column, read *easterly*, instead of "south-westerly" direction, &c., also lower down in the same column, where the mansion is said to face the "west," read the *south*.

Solidago Virgaurea.—"Where can I obtain a few plants of the Aaron's Rod, the Solidago Virgaurea? I shall be happy to pay postage or to send other seeds in return.—J. L. Carrick, *Vicarage, Witham Friary, Frome*."

Rockery (*Cleopatra*).—With your dying Birch trees as a centre, we think a small rootery would be more in character than a rockery. We always think it bad taste to blend roots and conglomerate of bricks, &c. The old trees would be useful for sustaining Clematis, &c., and the roots would soon be enough covered with Sedums, Ferns, &c. Unless the trunk is very rotten, it would hardly be worth while scooping it out for an Aloe, as if so rotten it would not stand long, and Aloes would thrive better in a rough box on the ground level. The best things to cover old rotten trunks with are Sempervivums, Sedums, and the common Polypody. By making holes in old stumps we have enticed robins, and that most elegant of British birds, the wagtail, to build their nests, and both became tame when well used.

Gardening Arithmetic (*J. T. B.*).—Surely a person who writes so well need not ask us how many plants will be required for a bed 50 feet long, 4 feet wide, to be placed in the rows 3 feet apart, and 2 feet asunder in the rows. If no more simple mode offers, take a measuring rule with inches marked in tenths, and 5 inches will thus represent 50 feet in length, and 4-10ths inch will represent the width of the bed. The bed, we presume, will have two rows, 3 feet by 2—rather thin planting for most things. The number of plants will be obtained at less trouble than making the inquiry. The other question is a little more puzzling. "Required the number of cubic feet in a bed 50 feet in diameter, and 1 foot deep," merely because there are so many modes for taking and finding the area of a circle. We will put you in the way of working out the problem for yourself. The diameter given, we can obtain very nearly the circumference by the old rule: As 7 is to 22, so is the diameter to the circumference. Perhaps a more correct mode is simply to multiply the diameter by 3.1416, the last four figures being decimals. The circumference being thus found nearly, as well as the diameter, the next thing is to find the area of the space bounded by the circumferential line. Here, again, various modes may be adopted. One mode is, to square the diameter and multiply by .7854. Another is, as 7 is to 22, so is the square of the radius to the area of the circle. The radius is half the diameter, in this case 25 feet. This multiplied into itself, and the product multiplied again, as above, by 22, and divided by 7, will give the area nearly. Another plan is to multiply the circumference and the diameter together, and then divide by 4. It must be kept in mind that a square foot contains 144 inches, and a cubic foot 1728 inches.

Protecting Plants in a Pit (*X. Y. Z.*).—The chief difficulty you will have in your pit, sunk 2 feet into clay, and floored with Portland cement, arises from the fact, that if the sides and ends of boards are not secure, damp will visit you from the clay; and if you spill water in winter it will be evaporated from the waterproof flooring, and rise again among the plants. You must, therefore, be careful not to spill water in winter. Your idea of double wooden walls is good, and, as stated lately, we would prefer the space between to be open if you can make that space airproof; if not, pack with felt, peat, sawdust, &c. Having double sashes for your pit or box, will also be useful, and the more so, that in mild weather you can take the upper one off. For tall plants you will want the depth you have—4 feet in front, and 9 behind; but if you want to keep a great many plants, say from 6 to 15 or 18 inches in height, we would have a rough sloping stage to fit the pit, and to be lifted out when not wanted, say at from 18 to 24 inches from the glass, and this will enable you to keep the plants near the glass, and the open space beneath will do much to secure equality of temperature. Even with your double lights you will need a

mat in a severe night, and a gallon bottle filled with hot water will also greatly help you.

Heated Greenhouse (*M. E. G.*).—With your trellis from 9 to 12 inches from the wall, you may grow the Passiflora and the Ipomœa well, without anything behind it; but you might have some rough clinkers against the flue or chimney. If you covered the trellis with the Passiflora, &c., you would not have light enough for Mosses and Ferns in the space between the wall and trellis. The moss, cocoa-nut, &c., would also be apt to sink, and if kept damp, as you suggest, it would soon rot the trellis. You might combine both purposes; have arches spanned for the climbers, and make a rough irregular wall with stones, boulders, clinkers, and cement, with spaces left for the Ferns, Mosses, Begonias, &c.

Names of Plants (*F. E. H.*).—Tacsonia mollissima; Desfontainia spinosa. (*Sarah Pierson*).—1, Leaf of the Tulip Tree, Liriodendron Tulipifera; 2, Cystopteris fragilis; 3, Rhynchospermum jasminoides, now called Parechites Thunbergii. (*W. O.*).—1, Adiantum capillus-Veneris; 2, Microlepia novæ-zelandiæ; 3, Adiantum hispidulum; 4, not received; 5, Selaginella Kraussiana; 6, Doodia caudata. (*D. C. G.*).—1, Sedum ibericum; 2, Sedum sexangulare; 3, Pellæa rotundifolia; 4, Davallia solida; 5, Adiantum formosum; 6, A. affine. (*E. L. J.*).—2, Litobrochia lucisa; 3, Asplenium monanthemum; 4, is most probably a state of Lastrea Filix-mas. (*G. S.*).—Æsculus macrostachya, or Pavia macrostachya. (*W. W., Reading*).—Momordica charantia. (*M. H.*).—1, Verbascum phlomoides (?); 2, Verbascum austriacum (?); 3, Hellanthus perfoliatus; 4, Francoa sonchifolia. (*J. H. S.*).—Rhus cotinus, the Sumach tree. (*D. G.*).—1, Lastrea oreopteris; 2 and 4, both Cystopteris fragilis; 3, Asplenium viride; 4, Nephrodium effusum. (*C. Williamson*).—Nepeta cæsia.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending August 17th.

Date.	Barometer.		Thermometer.				Wind.	Rain in inches.	General Remarks.
			Air.		Earth.

POULTRY, BEE, AND PIGEON CHRONICLE.

NOTES MADE DURING SOME RUSTIC RAMBLES.

What an odd little place is this! The ceiling is so low that I am positively nervous when I rise from my chair. A great beam runs across the room, reminding one of generations that have passed away who knew no better, but yet did what they could, and that is all we must expect. The room adjoining, designated the hall, but evidently intended for a sitting-room, although the front door opens into it, smells strongly of something quite the reverse of agreeable. What can it be? "Oh, sir," says the hostess, "it's only the straw beneath the matting, put there to keep the damp away!" Yet as I look out, there are evident signs of modern ideas and modern improvements. Elaborate iron supports for wheat-ricks, costing, I am told, £15 each, demonstrate the care the owner takes to guard his produce from petty thieves; while the new buildings, with the noble and really handsome hay-ricks in the yard, prove that a vigorous mind rules around. Look, too, at the horses, grand specimens of their class, evidently intended for work, and yet as handsome as one could wish. But the men interest me most; for they are such as I should like to see oftener—sturdy, stalwart, stout-built, Sussex peasantry that would gladden the heart of Mr. Fawcett, if only he could see them. To crown the prospect, there rises at no great distance a school newly built, the gift of a proprietor who recognises the saw of good Mr. Drummond, that "property has its duties as well as its rights." With such pleasant sights around, I must admit that I care little for the low ceiling of my sitting-room, or the damp smell of the hall.

I fear, however, I am rambling too far. I sat down to say a few words on poultry, but have not yet reached the starting-point. The Speckled Dorkings in front remind me of the theme I should pursue, while the crossbred Ducks confirm what I have always heard, and my host assures me is the case, that the Aylesburys are not adapted for the ordinary purposes of the farmyard.

How different was the scene a few days since! In a remote village of Northamptonshire I happened to hear that an old hen-wife had some White Dorkings which she highly valued. Proceeding to her house, I learnt she had kept the same strain for twenty years, obtaining them originally from one sitting of eggs, and never having introduced fresh blood from that time to this. The statement may appear incredible, but I believe it to be true. You can easily imagine the result—crooked backs and stunted forms appeared on all sides. "How many chickens have you this year?" I inquired. The old woman shook her head mournfully. "I set two hens, but have had no chicks." "How many did you have last year?" "It may be a dozen or fifteen," she replied. "I kept a few, but most on 'em I killed. But I ba'nt agoing to keep any more, as I find they don't pay me." "Of course they don't," was my answer; "if you farming folk refuse to apply to your poultry the same observation and skill you are compelled to apply to your land, you must not expect them to pay."

Rumbling five miles further, I heard of a young farmer who was reputed a great fancier, and who, at all events, is the first of his class that I have met who attempts to keep poultry on a large scale and on a scientific system. I have for some time intended to advocate his plan in the columns of the Journal; now, however, I can only describe what I have seen, while possibly some of your readers can give further details from their own experience. His plan is as follows:—

He has a number of small houses which run on wheels, and which are capable of accommodating from forty to seventy fowls. The cost of each of these he tells me, is from £3 10*s.* to £4, so that the experiment is at all events not an expensive one to begin with. These houses he places in the midst of his grass fields, as well as close to the ploughed lands, allowing them to remain there about a fortnight. They are cleaned out every day, and the manure is spread over the adjoining land. The allowance of food, a question often asked, but rarely answered, is a gallon of barley or oats for twenty-four fowls per diem. On the whole, he seemed quite satisfied that the experiment is a satisfactory one. Yet, I must confess, I was not quite satisfied with his management. Examining his yards I found that he had a large number of old birds, than which I cannot conceive a greater mistake, if fowls are to be profitable. No hen should, in my opinion, be allowed to live beyond a year or eighteen months, if profit is an object, and no cock beyond two years. You thus obtain a far larger number of eggs, and the hens, moreover, are fairly good eating when they are killed. But little regard, moreover, seemed to be paid to the sort of fowl, a point which is certainly of great importance. It is commonly said, that a cross between a Light Brahma and a Dorking is the most useful for practical purposes; but on this point I should like to hear further evidence. A henwife who supplies the London markets with early chickens, tells me that size is not a matter of importance, as small fowls bring as good a price as large; but it is important to keep a sort of which the chickens are not difficult to rear. The waste. I can apply no milder term, of poultry in most farmyards, is something terrible. This year I have lost five or six chickens, many of them hatched early in March, out of about seventy Dorkings; and yet I could name several farmyards where the loss has amounted to nearly 50 per cent., and generally, as it seems to me, through carelessness and neglect.

I cannot but believe that the system of keeping poultry in moveable houses would answer, if carried out systematically. An elderly man beyond hard work might be employed, at a cost of 9*s.* or 10*s.* per week. He would see the houses moved, and cleaned, the chickens fed, the doors closed at night, and the eggs duly collected. I should imagine that in this way in

a farm of 400 acres, with the ordinary outhouses, two or three thousand fowls might be kept, and I am persuaded that the experiment would be successful.—E. M. B. A.

"WHERE IS THE EXHIBITION?"

I think if secretaries of shows when inserting the date, &c., of their meetings would at the same time name the county or large town the place is near, it would be a great boon to exhibitors, as in many instances, although I have an atlas, I am at a loss to know whether the place is north or south, far or near, and therefore don't know whether it is worth while to enter or not.—Frank Graham.

[Our correspondent is not the only one who has made a similar complaint, and letters asking "Where is the Exhibition?" are continually received by us. There is one exhibition that to the time we are writing we do not know where it is to be held.—Eds.]

COMPOUND FOODS FOR FOWLS.

Mr. Wragg's recommendation of Dear's food will doubtless receive the attention it deserves, coming, as it does, from one of the most eminent breeders of the day; but let me suggest a caution or two to those who have not tried it, founded on an experience of eighteen months. It is, unquestionably, very useful for chickens, but then the question arises, Is it advisable or necessary to continue the use of it with full-grown fowls? I believe it is; that, in fact, the breeder who once uses it must continue its use, or his fowls will droop and die. I well remember going to one of my yards this spring, and noticing that the fowls did not look so well as usual. Something was evidently wrong, and I naturally began to make inquiries. At length I learnt that Dear's food had been discontinued for a week. As soon as the stimulant was added again, the birds resumed their former appearance. In another yard my experience was exactly similar, and a week's discontinuance of the food would soon tell a tale which would undeceive many who are now enthusiastic in their commendation of the new compound.

The truth, I am persuaded, is that Dear's food is like most other stimulants, it is all very well in its way, but yet requires much care in its use. Brandy, we know, is an excellent corrective, but the more water we drink with it the better it is for us. If we once accustom ourselves to take it in large quantities, we cannot well desist from the habit, without at all events suffering unpleasant consequences. I believe that breeders in time will find it necessary to diminish the amount of the stimulant as the birds grow older. Those who aim at size do not, I imagine, care to see "the rich red," of which your correspondent speaks, in chickens of three or four months old, or to find their pullets laying at about the same age. Having lately had an opportunity of comparing two yards, in one of which Dear's food was used, I must honestly say that I preferred the look of the birds in the yard where no stimulant was added to the ordinary food.

Let me also suggest a caution to those who are buying fowls. It will be very advisable to learn how the fowls have been fed before you buy them. If they have been accustomed to this stimulant, the purchasers must continue it, or they will probably lose their birds. Any of your correspondents who have a turn for chemical analysis would confer a favour on your readers if they would tell us the ingredients of this compound. I strongly suspect that malt dust and linseed enter largely into its composition.—E. M. B. A.

Without in any way wishing to dispute the high value of the prepared food that Mr. F. Wragg alludes to in his letter of last week, I would just say, for the help of the too-often-overlooked fancier of small means, that it is not necessary in prize-winning to spend money upon such kinds of food; at least, my own experience of the last three years dictates such conclusion, never having used any one kind of prepared food, though I have taken a fair amount of prizes, including cups and many first prizes. I have just received from the show my first two pens of chickens exhibited this year, one pen taking a cup, beating twenty-two pens of birds, the other pen taking the first prize in its class. These birds were only five months and a half old, and weighed 13½ lbs. and 15½ lbs. per pen, and competed in each case with older chickens, and fed, too, with such foods. If persons will feed liberally on the best of our home-grown grain, care being taken that all is eaten each meal; give clean water, clean runs, and clean houses, they have the same chance of winning, and I am sure their birds will live longer, and thereby be more profitable.—L'Ane.

DEWSBURY POULTRY SHOW.

The arrangements for this Show, held on the 13th inst., were very complete, and the attention devoted by the Committee to the specimens was of the most unexceptionable character. Nothing was left undone that could be done to insure perfect success, and all the pens were safely placed under commodious and perfectly waterproof tents. On the morning of the Show it rained incessantly, at four o'clock, but fortunately the day proved very fine, and a complete success was secured. This provision against stress of weather, cannot be impressed too strongly on the attention of all poultry committees who may purpose holding their meetings out of doors on similar occasions.

Although the bulk of the birds were necessarily more or less under moult, many were shown in first-class condition. Among the latter we may especially note the *Cochins*, *Brahmas*, and *Spanish* fowls. *Hamburghs* were very few, but very good, and the *Polands* were unusually perfect specimens. Some most excellent Game *Bantams*, both Black Reds, and also Duckwings, competed. The Black and the White *Bantam* classes were not so good in feather as could be desired. Of Aylesbury and Rouen *Ducks*, the entry was not large, but a few of the winning birds were first-rate.

Pigeons.—The Poutera and Carriers were a very good show. Mr. Fielding was, as usual, first and second for Owls, and in Almonds won with a good pair. In the class for Tumblers of any other variety, he was also first with a well-matched and good pair of Black Mottles. In Barbs, which was a very good class, Mr. J. Frith, jun., was first with a very good pair of Yellows, Mr. Horner being second with Blacks, this gentleman also winning with Jacobins, and gaining first and second prizes for Trumpeters; but we think Mr. Frith's Blacks were quite equal to the winners, and should not be surprised if they reversed positions some day. Mr. Hawley won in the Fantail class with a good pair, and Mr. Croft in Nuns, with Blacks of superior quality. We cannot take leave of this excellent Show without giving a word of praise to the managers, who had all the birds sent off the same evening.

Cochin-China.—1, C. Sidgwick, Ryddlesden Hall, Keighley. 2, J. Turton, Ackworth. *c*, J. H. Dawes, Birminghsm. *Chickens.*—1 and 2, C Sidgwick.

Spanish.—1, H. Beldon, Goitstock, Bingley. 2, J. Gornall, Bradford. *hc*, W. & F. Pickard. *Chickens.*—1. W. & F. Pickard. 2, H. Beldon.

Dorkings.—Prize, W. H. King, Moss Mill.

Brahma Pootra.—1, E. Leach. 2, C. Layland. *Chickens.*—1, M. Scott, Cote, Idle. 2, W. Gamon, Chester. *hc*, E. Leach, Greave House, Rochdale.

Game (Black Red).—1, G. Noble, Stsincliffe, Batley. 2, C. Chaloner, Whitwell, near Chesterfield. *c*, H. Beanland, Bradford. *Chickens.*—1, J. Crosland, jun., Wakefield. 2, C. Chsloner. *c*, E. A. Johnson, Wathupon-Dearne.

Game (Brown Red).—1, C. Chaloner, Whitwell, near Chesterfield. 2, H. Jowett. *hc*, J. Crosland, Wakefield. *Chickens.*—1, H. Hatton, Cleckheaton. 2, H. Jowett. *c*, T. Dyson, Halifax; H. Jowett.

Game (Duckwings and other Greys and Blues).—1, H. Jowett. 2, G. Noble. *c*, J. Fell. *Chickens.*—1, C. Chaloner. 2, T. Dyson, Halifax.

Game (Any other variety).—1, H. C. & W. J. Mason. 2, W. Fell. *Chickens.*—1, W. Whiteley, Liversedge. 2, E. Noble, Halifax. *c*, H. C. and W. J. Mason, Drighlington.

Hamburghs (Gold or Silver-spangled).—1 and 2, H. Beldon. *hc*, S. and R. Ashton, Mottram. *Chickens.*—1 and 2, H. Beldon.

Hamburghs (Gold or Silver-pencilled).—1 and 2, H. Beldon. *hc*, S. S. Smith, Northowram, Halifax. *Chickens.*—1, H. Beldon. 2, W. Jagger, Ford Mill, Horbury. *hc*, S. Smith.

Hamburghs (Black).—1, H. W. Illingworth. 2, C. Sidgwick. *Chickens.*—1, C. Sidgwick. 2, S. Butterfield, Keighley.

Polands (Gold or Silver).—1 and 2, H. Beldon. *Chickens.*—1 and 2, H. Beldon.

Polands (Any other variety).—1, T. Dean, Keighley. 2, W. Gamon. *c*, Mrs. E. Proctor, Hull. *Chickens.*—Prize, W. Gamon.

Bantams (Black).—1 and 2, Master F. Ridgway, Dewsbury. *hc*, Messrs. S. & R. Ashton; W. Brotherton. *c*, H. Beldon.

Bantams (White).—1, S. & R. Ashton. 2, J. Kaye, Stainclifle.

Game Bantams.—1, W. F. Entwisle, Leeds. 2, J. Crosland, jun. *hc*, J. R. Robinson, Sunderland. *c*, G. Noble, Stsincliffe, Batley.

Ducks (White Aylesbury).—Prize, E. Leach, Rochdale.

Ducks (Rouen).—1, E. Leach. 2, W. Gamon.

Rabbits.—*Lop-eared Buck.*—1, T. Ingham, Leeds. 2, C. Gravil, Thorne. *hc*, B. Hudson, Hull. *Lop-eared Doe.*—1, A. H. Easten, Hull. 2, F. Mitchell, Bowling Park, Bradford. *hc*, T. Ingham, Leeds. *Any other Variety.*—1, A. H. Easten, Hull (Himalayan). 2, E. Farrance, Dewsbury. *hc*, T. Mitchell, Bradford (Himalayan).

PIGEONS.

Pouters.—*Cock.*—1, E. Horner, Harewood, Leeds. 2 and *c*, R. Fulton, Deptford. *hc*, W. Gamon, Chester. *Hen.*—1, E. Horner. 2, R. Fulton. *hc*, R. Fulton; E. Horner.

Carrier.—*Cock.*—1 and 2, R. Fulton. *hc*, A. Smith, Skipton; W. Whittaker, Belper; R. Fulton. *Hen.*—1 and *c*, R. Fulton. 2, W. Whittaker, Belper. *hc*, A. Smith, Skipton; R. Fulton.

Tumblers (Almond).—1, J. Fielding, jun., Rochdale. 2, R. Fulton. *c*, J. Hawley, Bingley.

Tumblers (Any other variety).—1, J. Fielding, jun. 2, R. Fulton. *hc*, J. Hawley; W. Whittaker; R. Fulton.

Turbits.—1, E. Horner. 2, Marshall & Pickering, Driffield.

Barbs.—1, J. Frith, jun , Webster Hill, Dewsbury. 2, E. Horner, *hc*, J. Fielding, jun.

Jacobins.—1, E. Horner. 2, R. Fulton. *hc*, J. Hawley.

Trumpeters.—1 and 2, E. Horner. *hc*, J. Frith, jun.; W. Gamon.

Owls.—1 and 2, J. Fielding, jun. *hc*, T. Eggleston, Halifax,

Fantails.—1, J. Hawley. 2, E. Horner.

Nuns.—1, W. Croft, Killinghall, Ripley. 2, H. Yardley.

Dragoons.—1, H. Yardley, Birmingham. 2, W. Whittaker. *hc*, J, Senior, Batley Carr.

Antwerps.—1, H. Yardley. 2, J. Crosland, jun. *hc*, W. Whittaker.

Any other Variety.—1, E. Horner (Red Swallows). 2, H. Yardley. *c*, W. Whittaker (Hyacinths).

Edwd. Hewitt, Esq., of Birmingham, judged the poultry; and M. Hedley, Esq., of Redhill, Surrey, the Pigeons and Rabbits.

LOWESTOFT POULTRY SHOW.

(*From a Correspondent.*)

This Show was held on the 11th and 12th inst. There was a great increase in the number of entries this year. The pens contained many birds of considerable merit, and many of the pens in the chicken classes will be heard of again, but some of the birds had not arrived when the Judges awarded the prizes. Two pens that doubtless would have been winners did not arrive till six o'clock on the evening of the first day of the Show.

There were classes for adult birds and chickens, Mr. Gilliver took the cup for *Game* with a beautiful pen of Brown Reds; Mr. Matthews took the prizes in the chicken class with some good birds. The *Dorking* cup went to a pen of birds in the adult class shown by Mr. Parlett, and in the chicken class the prizes went to promising chickens. The *Spanish* cup was carried off by Mr. Newbitt, with a pen of good birds, and in the chicken class the pens shown by Mr. P. H. Jones and Mr. James were worthy of the prizes. Mr. Horace Lingwood showed a splendid pair of Partridge *Cochins* in the chicken class, which carried off the cup against twenty-three pens. The *Brahma* cup was awarded to Mr. Dowsett for a pen of Dark birds, and in the chicken class Mr. H. Lingwood was first. The *Hamburghs* were not numerous, but some pens were excellent, particularly Mr. Tickner's Gold-pencilled which took the Hamburgh cup. The *Bantam* cup was awarded to a very beautiful pen of White Japanese shown by Miss M. Jodrell; Messrs. Crosland, Adams, and Entwisle carried off the remaining prizes for Bantams.

Pigeons were indeed a show of themselves, each class was well filled, and many first-class birds were shown in every class, especially in Carriers. Messrs. Massey & Fulton showed some good Black cocks; but Mr. Yardley's Dun hen has a remarkable eye and was worthy of the first prize. Mr. Fulton's Black was all that could be desired in symmetry and carriage, but not so good in eye as the first-prize bird, Mr. Wren showed a young Dun hen eleven months old, a very promising bird, which will doubtless be heard of again in a prize pen. Mr. Fulton was as usual invincible in the Ponter classes; the first-prize Blue is a grand bird. Some pens of Almonds were very good in head and beak, but it is difficult to find many pens well matched. The long-faced Tumbler class was well filled, and amongst the pens were some good Beards and Mottles. Messrs. Hawley, Fulton, Jones, and Massey, showed good Barbs; and the Fantails were a strong class. Mr. Hawley was first with a good pen. Antwerps were numerous and good, but a very difficult class to judge. The "Variety class" contained a number of very good birds. Black Owls took first and Silver Barless Ice second; Red Turbits an extra second. The race for the Pigeon cup was very close, Mr. Fulton making thirty-six points, and Mr. Hawley, to whom the cup was awarded, thirty-seven.

Game (Any variety).—1, Cup, and *hc*, W. Gilliver, Polesworth, near Tamworth (Black Reds). 2, S. Matthews, Stowmarket (Black Reds). *Chickens*,—1 and 2, S. Matthews (Black and Brown Reds). *c*, W. Rayner, Ipswich (Brown Reds).

Dorkings (Any variety).—1 and Cup, P. Parlett, Great Baddow, Chelmsford (Coloured). 2, Henry Lingwood, Bark ng, Needham Market. Local, G. W. D. Palmer, Pakefield. *hc* J. Frost, Parham, Wickham Market (Colonred). *c*, Mrs. Brackenbury, Thorpe Hall Farm, Downham (Colonred). *Chickens*.—1, T. Briden, Earby, near Skipton. 2, J. Frost (Coloured). Local, C. H. Skeels, Kirkley. *hc*, D C. Campbell, M.D., Brentwood; Rev. F. Tearle, Gazeley Vicarage, Newmarket (White). *c*, F. Parlett Coloured).

Spanish.—1, Cup, and 2, T. C. & E. Newbitt, Epworth. Local, W. B. Farrett, Lowestoft. *hc*, F. James, Peckham Rye. *c*, J. Stephens, Walsall. *Chickens*.—1, F. James. 2, P. H. Jones, Fulham, London. Local, W. B. Ferrett.

Cochin-China (Any variety).—1, Henry Lingwood (Buff). 2, Horace Lingwood, Martlesham, Woodbridge (Partridge). *hc*, J. Stephens. *c*, Col. Cockburn, Bracondale, Norwich (White); Henry Lingwood (Buff); Horace Lingwood (Partridge). *Chickens*.—1 and Cup, Horace Lingwood (Partridge), 2, F. W. Rust, Hastings Buff). *hc*, Miss Hales, Canterbury (White); W. Tippler, Roxwell, Chelmsford (Buff). *c*, Mrs. Burrell, Stoke Park, Ipswich.

Brahma Pootra (Any variety).—1 and Cup, H. Dowsett (Dark). 2, Mrs. Burrell. *c*, Horace Lingwood (Dark). *Chickens*.—1, Horace Lingwood (Dark). 2, Mrs. Burrell. *hc*, H. Dowsett (Dark).

Hamburghs (Golden-pencilled).—1 and Cup, W. K. Tickner. 2, T. C. and E. Newbitt. Local, J. Taylor, Lowestoft. *c*, C. Havers, The Beacons, Ingatestone; J. Laming, Cowburn, Spalding.

Hamburghs (Silver-penci led .—1, H. Pickles, jun., Earby, Skipton. 2, J. Laming. Local, W. Maddison.

Hamburghs (Golden-spangled).—1, J. F. Loversidge, Newark-on-Trent. 2 and Local, L. Wren, Lowestoft.

Hamburghs (Silver-spangled).—1, J. Laming. 2, Rev. F. Tearle. Local, J. B. Bly, Lowestoft. *c*, J. W. Tooley, Downham Market; R. Fulton, Deptford.

Hamburghs (Any variety).—*Chickens*.—1, H. Pickles, jun. 2, W. K. Tickner, Ipswich (Golden-pencilled). Local, J. B. Bly (Silver-spangled). *hc*, Rev. F. Tearle (Silver-spangled).

Any Distinct Variety not before Mentioned.—1, J. Laming (Polands). 2, Col. Cockburn (Houdans). *hc*, Mrs. Burrell (Silkies); W. Dring, Faversham (Houdans). *c*, W. Tippler (La Flèche).

Selling Class (Any variety).—1, T. C. & E. Newbitt. 2, S. Felgate, Ipswich (Light Brahma). *hc*, F. Parlett (Dorkings); R. R. Parker, Ipswich (Golden-pencilled Hamburghs); W. Dring (Houdans). *c*, W. H. Mitchell, Moseley, Birmingham (Game); Mrs. Brackenbury (Aylesbury Ducks).

Game Bantams (Any variety).—1, J. Crossland, jun., Wakefield. 2, W. Adams, Ipswich. Local, C. H. Skeels. *c*, W. F. Entwisle, Leeds (Black-breasted).

Bantams (Any other variety).—1, Cup, and Local, Miss M. Jodrell, Gisleham Rectory (Japanese). 2, Miss A. Hodson, North Petherton, near Bridgewater (Sebrights). *Chickens*.—1, Miss A. Hodson (Sebrights). 2, W. F. Entwisle (Black-breasted Red). *c*, E. Prentice, Stowmarket (Black-breasted Red).

Ducks (Rouen).—1, J. T. Ashley, Litcham, Norfolk. 2 and Local, G. W. D. Palmer.

Ducks (Aylesbury).—1, C. Havers. 2 and *c*, Mrs. Burrell. *hc*, Major C. J. Ewen, Norwich.

PIGEONS.

Carriers.—*Cock*.—1, R. Fulton. 2, W. Massey, Spalding. *hc*, R. Fulton; J. Hawley, Bingley. *c*, L. Wren. *Hen*.—1, H. Yardley, Birmingham. 2, R. Fulton. *hc*, R. Fulton; L. Wren; J. Hawley. *c*, W. Massey; P. H. Jones.

Ponter.—*Cock*.—1 and 2, R. Fulton. *hc*, P. H. Jones. *Hen*.—1 and 2, R. Fulton. *c*, P. H. Jones.

Tumblers (Short-faced).—1, R. Fulton (Almonds). 2, J. Hawley. *hc*, R. Fulton (Mottles). *c*, M. Beazor, Yarmouth (Almonds); P. H. Jones; J. Hawley.

Tumblers (Any other variety).—1 and *hc*, J. Hawley. 2, Misses E. & A. Wren, Lowestoft (Yellow Beards).

Barbs.—1, J. Hawley. 2, R. Fulton. *hc*, W. Massey; P. H. Jones. *c*, W. Massey.

Fantails.—1, J. Hawley. 2, H. Yardley. *hc*, P. H. Jones. *c*, W. Massey; J. T. Ashley.

Antwerps.—1, J. Hawley. 2, W. H. Mitchell. *hc*, H. T. Yardley; J. Hawley. *c*, P. H. Jones; J. Hawley.

Any Distinct Variety.—1, J. Hawley. 2, Hon. Mrs. Paget, Scole (Ice). Extra 2, P. H. Jones (Turbits). *hc*, R. Fulton (Owls); P. H. Jones (Owls, Nuns, Magpies, and Jacobins). *c*, W. Massey; J. T. Ashley (Runts) J. Hawley.

Selling Class (Any variety).—1, Hon. Mrs. Paget (Owls). 2, P. H. Jones (Barbs). *c*, W. Massey; P. H. Jones (Jacobins); L. Wren (Short-faced Tumblers); J. Hawley.

Judges.—Rev. T. L. Fellowes, Honingham Rectory, Norwich, and W. B. Tegetmeier, Esq., London.

ALDBOROUGH AND BOROUGHBRIDGE POULTRY SHOW.

This was a very good Show, and was held on the 13th inst. in the interesting grounds of Aldborough Manor. The quality of the poultry exhibited was good, and it is surprising that exhibitors will show such stock for small prizes. The day was fine, the poultry well attended to, the pens good, and the Show altogether a success.

Dorkings.—1, H. S. Thompson, Kirby Hall. 2, W. Bearpark, Ainderby Steeple.

Spanish.—1, W. Bearpark. 2, W. & F. Pickard, Thorner, near Leeds. *hc*, W. & F. Pickard.

Game.—1, J. Watson, Knaresbrough. 2, W. Bearpark. *c*, J. Watson; G. Carter, Sandhill, Bedale.

Cochin-China.—1, W. Barnes, Thirsk. 2, W. & F. Pickard. *hc*, W. Barnes. *c*, J. Walker, Hay-a-Park, Knaresborough; G. Robinson, Sessay.

Brahma Pootra.—1, F. Powell, Knaresborough. 2, F. Horsman, Boroughbridge. *hc*, H. S. Thompson. *c*, Miss E. A. Dalton, Sleningford Grange, Ripon.

Chickens.—1, W. & F. Pickard. 2, W. Barnes. 3 Miss E. A. Dalton. *hc*, H. S. Thompson; W. Barnes. *c*, W. Metcalf, Grafton High Bar; W. Bearpark; G. Robinson, Easingwold; F. Horsman; J. Watson.

Hamburghs.—*Golden-spangled*.—1 and 2, J. Walker. *hc*, W. Bearpark. *Golden-pencilled*.—1, J. Walker. 2, F. Horsman. *c*, F. Horsman. *Silver-spangled*.—1, J. Walker. 2, J. Best, Boroughbridge. *Silver-pencilled*.—1, J. Walker. 2, W. Bearpark.

Poland.—1, C. Walker, Boroughbridge. 2, W. Lousdale, Aldborough.

Chickens.—1 and 2, J. Walker. 3, F. Horsman. *hc*, W. Bearpark. *c*, C. Walker.

Game Bantams.—1, J. Pennington, Thirsk. 2, F. Powell. *hc*, J. Walker; G. Carter, Sandhill, Bedale. *c*, Miss E. M. Ellerby, Easingwold.

Bantams (Any variety).—1, J. Walker. 2, F. Powell. *hc*, J. Cartwright, Sowerby, Thirsk.

Bantams (Any other variety).—1, Rev. J. G. Milner, Bellerby, Leyburn. 2, J. Walker. *c*, R. Wilson, Thirsk.

Turkeys.—1, T. Smith, Staveley. 2, I. Moorey, Mulwith. *hc*, F. Parker, Roecliffe. *Poults*.—1, F. Parker. 2, I. Moorey.

Geese.—1, J. Walker. 2, S. Renton, Ox Close, Ripon. *hc*, S. Renton. *Goslings*.—1 and 2, Mrs. Smith, Humburtoo. *hc*, I Moorey. *c*, S. Renton.

Ducks (Aylesbury).—1, G. Robinson. 2, J. Cuthbertson, Aldborough. *c*, Miss E. A. Dalton. *Ducklings*.—1, H. S. Thompson. 2, J. Handley, Skelton, Ripon.

Ducks (Rouen).—1 and 2, C. Graham, Aldborough. *hc*, A. S. Lawson, Aldborough Manor. *Ducklings*.—1, J. Handley. 2, J. Mason, Rooker Hill.

Ducks (Any other variety).—1, Rev. J. G. Milner. 2, J. Walker. *hc*, J. Walker. *hc*, Miss E. A. Dalton. *c*, C. Rutherford, Thirsk.

Guinea Fowls.—Prize, S. Renton.

Selling Class.—1, W. & F. Pickard. 2, J. Mason. *hc*, J. Walker; J. Watson; G. Carter.

PIGEONS.—*Pouters.*—1, W. Bearpark. 2, J. Walker. *Carriers.*—1, J. Masson. 2, J. Greaves, Brampton Hall. *Trumpeters.*—1, J. Cundale, Copt Hewick, Ripon. 2, R. Wilson. *hc*, J. Mason. *Jacobins.*—1, J. Mason. 2, W. Bearpark *hc*, J. Walker. *Fantails.*—1 and 2, J. Mason. *c*, J. Walker; W. Bickerdike, jun.; R. Wilson. *Tumblers.*—1 and 2, J. Mason. *c*, J. Greaves; R. Wilson. *Barbs.*—1, J. Fox, Thirsk 2, R. Wilson. *c*, J. Cundale. *Nuns.*—Prize, W. Bearpark. *Turbits.*—1, R. Wilson. 2, J. Mason. *hc*, W. Bearpark. *Any other Variety.*—1, J. Mason. 2, J. Cundale. *hc*, J. Mason; R. Wilson. *c*, J. Cundale. *Selling Class.*—1 and 2, J. Mason. *hc*, J. Fox. *c*, T. Scott, Broom Close, Boroughbridge.

RABBITS.—*Buck* (Any breed).—1, Slade. 2, G. Rutherford, Thirsk. *hc*, J. Ridsdale, Boroughbridge. *Doe* (Any breed).—1, I, Slade. 2, A. S. Lawson, Aldborough Manor. *hc*, I. Slade. *c*, J. Topham, jun., Boroughbridge; A. Geldart, Boroughbridge.

EXTRA STOCK.—*hc*, R. Turner, Dishforth.

JUDGE.—Mr. E. Hutton, Pudsey.

HEXHAM POULTRY SHOW.

THE poultry Show in connection with the Northumberland Agricultural Society's annual Exhibition was held at Hexham on the 10th inst. There were 113 entries, and the following are the awards made :—

DORKINGS.—1, J. White, Warlaby, Northallerton. 2, J. H. Wilson, St. Bees. *c*, H. Pickles, jun., Earby.

GAME (Any variety).—1 and 2, J. Brough, Carlisle. 3, W. Walton, Locklake, Alston. *c*, J. H. Wilson.

SPANISH.—1, J. H. Wilson. 2, W. Bearpark, Ainderby Steeple. 3, J. Elliott, Langley Hill Top.

BRAHMAS (Any colour).—1, C. Layland, Morris Brook, Warrington. 2 and 3, J. Shorthose, Newcastle-on-Tyne.

COCHIN-CHINA (Any variety).—1, J. Shorthose. 2, G. H. Proctor, Durham. 3, C. Layland. *c*, Mrs. Dees, Riverdale, Bellingham; J. Dodds, Nedderton.

HAMBURGHS (Any variety).—1, H. Pickles. 2, W. Bearpark. 3, F. E. Schofield, Morpeth.

GAME BANTAMS (Any variety).—1, J. R. Robinson, Sunderland. 2, W. E. Entwisle, Leeds. 3, J. Crosland, Wakefield. *hc*, J. R. Robinson; J. Crosland.

BANTAMS (Any variety except Game).—1, L. & R. Ashton, Roe Cross, Mottram. 2, H. Pickles, jun. 3 and *hc*, R. Youll, Sunderland. *c*, Mrs. Chester, Hexham.

POLISH.—1, H. Pickles, jun.

BARNDOOR (Any variety).—1, Rev. J. G. Milner, Leybourn.

GEESE (Any colour).—1, Miss Wilson, Woodhorn Manor, Morpeth. 2, J. Shorthose.

DUCKS.—*Aylesbury.*—1 and 2, J. Shorthose. 3, J. Coulson, Shotley Hall. *c*, Mrs. Dees. *Rouen.*—1, Miss Wilson, Morpeth. 2, Rev. J. G. Milner. 3, Mrs. B. Ord, Whitfield Hall, Haydon Bridge. *Any variety except Aylesbury or Rouen.*—1, F. E. Schofield. 2, J. Coulson. 3 and *c*, Rev. J. G. Milner. *hc*, O. Teasdale, Chapel Mew Houses, Coanwood.

TURKEYS (Any variety).—1 and 2, Miss Wilson. 3, Miss M. Lambert, Elrington Hall.

JUDGE.—Mr. R. Teebay, Fulwood, Preston.

COTTINGHAM POULTRY SHOW.

THIS Show took place on the 11th inst. The following is the list of awards :—

SPANISH.—1, G. Holmes, Driffield. 2, W. Richardson. *Chickens.*—1, G. Holmes. 2, R. Loft, Woodmansey. *Cock* (Any age).—1, J. Stable, Driffield.

DORKINGS.—1, G. Holmes. 2, — White, Driffield. *Chickens.*—1, R. Robson. 2, — White. *Cock* (Any age).—1, — White.

COCHIN-CHINA.—1, R. Richardson. 2, R. Robson. *Chickens.*—1, R. Dawson. 2, Mrs. Robson. *Cock* (Any age).—1, R. Dawson.

GAME.—*Cock.*—1, W. Boyes. 2, H. M. Julian. (Black-breasted or other Reds).—1, H. M. Julian. 2, W. Boyes. *Chickens.*—1, H. M. Julian. 2, W. Boyes. *Cock* (Any age).—1. H. M. Julian. (Any other variety).—1, H. M. Julian. 2, W. Boyes. *Chickens.*—1, H. M. Julian. 2, W. Boyes. *Cock* (Any age).—1, H. M. Julian.

POLANDS.—1 and 2, Mrs. Procter. *Chickens.*—1 and 2, Mrs. Procter. *Cock* (Any age).—1, Mrs. Procter.

HAMBURGHS (Golden-spangled).—1 and 2, G. Holmes. *Chickens.*—1, G. Holmes. *Cock* (Any age).—1, W. G. Drewery. (Silver-spangled).—1, G. Holmes. 2, R. Cook. *Chickens.*—1, G. Holmes. 2, J. Richardson. *Cock* (Any age).—1, G. Holmes. (Silver-pencilled).—1, T. Holmes. 2, G. Holmes. *Chickens.*—1, G. Holmes. *Cock* (Any age).—1, G. Holmes.

FARMYARD CROSS.—1, T. Coverdale. 2, G. Holmes. *Chickens.*—1, G. Bromby. 2, Mrs. J. Coverdale. *Cock* (Any age).—1, J. Coverdale.

SELLING CLASS.—1, R. Loft. 2, G. Loft. *Cock* (Any age).—1, G. Holmes.

ANY DISTINCT VARIETIES NOT PREVIOUSLY CLASSED.—1, G. Loft. 2, R. Loft. *Chickens.*—1, G. Loft. 2, Miss Dobree. *Cock* (Any age).—1, R. Loft.

BANTAMS (Gold).—1, — Harrison. 2, Miss Dobree. *Chickens.*—1, — Harrison. 2, J. Ringrose. *Cock* (Any age).—1, — Harrison.

GAME BANTAMS.—1, J. R. Duggleby. 2, R. Robinson. *Chickens.*—1, R. Robson. 2, — Hardy. *Cock* (Any age).—1, — Duggleby. Any other variety.—1, R. Fleming. 2, T. C. Harrison, Hull. *Chickens.*—1 and 2, T. C. Harrison. *Cock* (Any age).—1, T. C. Harrison.

GEESE.—1, O. A. Young, Driffield. 2, T. C. Harrison.

DUCKS (Any variety).—1 and 2, T. C. Harrison. Special, R. Richardson and G. Holmes.

TURKEYS.—1, O. A. Young. 2, J. Kyme.

PIGEONS.—*Croppers.*—1, H. Yardley. 2, J. Key. *Carriers.*—1, W. Camney. 2, H. Yardley. *Turbits.*—1, H. Lawson. 2, H. Yardley. *Trumpeters* —1, C. N. Lyth. 2, D. M. Collin. *Jacobins.*—1, H. Yardley. 2, R. Fleming. Judges' prize, C. N. Lyth. *Fantails.*—1 and 2, C. N. Lyth. Judges' prize, H. Taylor. *Dragoons.*—1, W. Campney. 2, C. Marwood. *Tumblers.* —1, C. N. Lyth. 2, H. Yardley. Judges' prize.—W. G. Drewery, Beverley. *Barbs.*—1, J. Key. 2, A. Waites. *Nuns* —1, F. E. Thompson. 2, J. R. Duggleby. Any other variety.—1, H. Yardley.

RABBITS.—*Lop-eared Buck.*—1, P. Ashton, Hull. 2, J. Fletcher, Hull. *Lop-eared Doe.*—1, J. R. Moore. Any variety.—1, Miss Fletcher. 2, P. Ashton.

CANARIES.—*Belgian.*—1 and 2, W. Needler. 3, W. H. H. Hutchinson. *Norwich.*—1, E. Leeman. 2, Miss Widdall. *Coppy or Turn Crown.*—1, E. Seaman. 2, G. Pexton. *Yorkshire.*—1, E. Seaman. 2, G. Pexton. *Any other variety.*—1, A. Lewis. 2, G. Pexton. *Goldfinch Mule.*—1, A. H. Easton. 2, Mrs. Garbutt. *Goldfinch Cock.*—1, J. Key. 2, — Proctor. *Nest of Four Young Canaries.*—1, Mrs. Downs. 2, W. Needler. *Any other variety of Small Birds.*—1, W. Dale. 2, H. Sage.

JUDGES.—D. Fergnson, Esq., Risby Park, and W. Boulter, Esq., Beverley.

ORMSKIRK AND SOUTHPORT POULTRY SHOW.

THIS was held on the 11th inst., in conjunction with an Agricultural and Horticultural Show. The entries of poultry and Pigeons amounted to 204. It is not too much to say that seldom has there been a better collection. Some of the *Dorkings* could scarcely be surpassed in any part of England, and the whole class, adults and chickens, may be set down as very good. As regards *Cochin-China* fowls there was the best show we have seen for some time. The *Brahma Pootras*, though there were not many of them, deserved great praise. Of *Spanish* the adults were first-class, and the chickens were of such excellent quality that the Judges must have had great difficulty in deciding; nearly all the birds were highly commended. There were only few entries of *Game* fowls, and these were not very good. It would seem that this class of birds is not bred with the same care as it was formerly. The competition was close for the best Golden-spangled *Hamburghs*, which were very good. The Silver-spangled were still better, and deserve the highest commendation. There were exhibited in these classes some of the choicest birds in England, Mr. Beldon, from Bingley, being very successful. The *Ducks* were excellent, particularly some Aylesbury Ducks from that place. The *Geese* were good, and the *Turkeys*, especially one splendid pen from Rochdale, were much admired. The entries of *Pigeons* were not very numerous, but those exhibited were choice birds.

DORKINGS.—*White.*—1, J. Robinson, Garstang. 2, Mary Fairhurst, Woodlands, Ormskirk. *Chickens.*—1, J. Robinson. 2, Mary Fairhurst. *Coloured.*—1, J. Robinson. 2, Admiral Hornby. *hc*, Admiral Hornby; T. Hornsby, Lathom; Lady Scarisbrick. *Chickens.*—1, Admiral Hornby. 2, T. Briden, Earby. *hc*, T. Briden, Earby; E. Shaw, Oswestry; J. Robinson.

JUDGES.—Mr. Joseph Hindson, Everton, Liverpool, and Mr. Richard Teebay, Fulwood, Preston.—(*Ormskirk Advertiser*).

CONVULSIONS IN YOUNG RABBITS.

I HAVE kept tame Rabbits for some time, and have found in almost all cases that the young ones die when about six weeks old. The Rabbits seem quite right one hour, and the next hour they are struggling and rolling over and over until they die. They do not sometimes die for hours. I should be glad if you would give an opinion as to the cause of death, and the remedy. The Rabbits do not die from too much green meat, for they have little or none. The food they have is carrots and carrot tops, bran, meal, &c. They are kept in a very large wire run, open

at the top. The young ones die almost as soon as they leave the old one.—E. G. D.

[Young Rabbits when eight weeks old pass through a kind of moult, and to them it is the most critical time of their lives. They should be left with the doe until that event is over—say nine or ten weeks, then remove all but one of the smaller ones to dry up the milk of the doe, and feed the removed ones upon bread and milk, with crushed oats as a dry food. A little malt culms mixed with the oats will be beneficial. A few common peas soaked for twelve hours are good—say twice a-week. All green food should be given dry, as the damp gives the Rabbits the "rot." The hutches should be 2 feet from the ground, dry and warm, and closed at night, to protect the Rabbits from the damp air. Clean the hutch well with a brush and a solution of disinfecting powder, then sprinkle with sawdust and ashes mixed. Oat straw and old hay may be given freely, but new hay is not good, as the Rabbits become swollen after eating it. I have cured old Rabbits of these convulsions by giving half a grain of camphor crushed in a teaspoonful of warm water. As a rule, most diseases may be prevented by the feeding and care bestowed.—C. Rayson.]

LIGURIANS IN JERSEY.

Perhaps the doings of my Ligurians in this island may interest some of your readers. Last year I purchased of Messrs. Neighbour a black stock with an Alpine queen at the head, this I brought over safely in June, the bees suffering but little from their confinement for two days. Thus far I was successful, but owing to the long drought they made very little honey after their arrival, for they consumed about 11 lbs. of sugar during the winter, but by careful feeding they survived, and in May threw off a very heavy swarm, which chose a flat wall covered by a peach tree for its resting place. As many of the bees got behind the branches it was a very difficult matter to dislodge them; however, they were safely housed in one of Neighbour's improved cottage hives. The stock hive threw off a second and third swarm, which were united and sold. In due time Neighbour's hive was supered, and after some hesitation the bees began to work; but my hopes of a good super were soon disappointed, for they ceased to work, and on July 9th threw off a virgin swarm, weighing 5 lbs. As the hive was still strong with bees it seemed better not to return it, so I hived it in an old straw hive *pro tem.*

I did not succeed in obtaining another hive for five days, but having secured one, I transferred the bees; but the Woodbury did not suit their taste, for next day they decamped and settled in a neighbour's garden. Having hived them again, I fixed the comb they had previously constructed into the Woodbury frames, and in the evening put them in again, but next day they decamped again. This time I put them into an improved cottage hive, but this did not suit them, for they decamped out of that and went off to a deserted hive some 300 yards away. In the evening I lifted it from the "stance" to bring it away, and it then became evident that the wax moth was in it, so I determined to rout them out of it. Accordingly, in conjunction with another apiarian (one who can claim the honour of having first introduced the Ligurians here), we took possession of the queen; we then caged her on the top of the Woodbury, so that she could communicate with her subjects. This was done about noon, so by evening they had quite settled down, as I thought; but next day they made two attempts to decamp, but finding the queen was not with them they soon returned, and making a virtue of necessity they set to work, so forty-eight hours after their last attempt to decamp I let the queen loose. A second swarm followed this most refractory one, but was returned to the parent hive. The queen which headed the second swarm was quite dark-coloured, whilst the mother is a beautifully-marked Ligurian, and breeds pure Ligurians. Is this usual?—Cantan.

DRIVING BEES.

Mr. Francis Chapman wishes to know, were he to drive bees into empty hives during the present month, if they would live through the winter—that is, of course if they were fed; also the best mode of feeding them. The people in his neighbourhood give common brown sugar, and say the bees are fond of eating little birds, such as sparrows, &c.

[You should drive the inhabitants of two or three hives into one, and then feed them with simple syrup made of lump sugar in the proportion of three parts sugar to two of water (by weight), by means of an inverted pickle-bottle which must be filled every evening, until they attain a nett weight of at least 18 lbs. You may in this way form stocks from condemned bees which will probably survive the winter; but you would do much better to utilise the refuse pieces of worker combs, as well as the bees, by means of frame hives, in the manner detailed by Mr. Woodbury in Nos. 356, 357, 358, and 369 of our New Series. Brown sugar is inferior to lump sugar as food for bees, and the idea of their being carnivorous has been completely disproved.]

LIGURIAN BEES.

I possess three hives of Ligurians, one of which has, however, unfortunately, become hybridised. The original Ligurian queen is still alive, but as she is at the head of a swarm which came off lately, and one which has given me much trouble to settle, I am afraid to disturb the bees by taking her away; moreover, it is too late in the season to deprive a hive of its queen. The hybridised stock is in a Woodbury hive, so there would be but little difficulty in introducing a pure queen if I could procure one. If the hybridised stock be left alone, I am afraid of the hybridised drones next year uniting with the pure queens from my other stocks.—Cantan.

[If the hybridised queen be, as we imagine, pure-bred, she will breed pure drones in spite of the cross. Mr. Woodbury, of Mount Radford, Exeter, will, upon application being made to him, put you in the way of obtaining pure Italian queens at a cheap rate in the autumn.]

OUR LETTER BOX.

Nettles and Young Turkeys (*E. R. P.*).—We do not believe stinging nettles are injurious to any kind of poultry; we encourage them as shelter for our chickens, and they live among them. In many parts they give nettles chopped up and mixed with meal, which is an excellent food.

Black Hamburghs (*Black Hamburgh*).—We consider the birds pure. We can only add, we advise you to breed from the faultless birds only. There is, says an old proverb, "a skeleton in every house," and those who know the secrets can tell you if they will, that the uniformity of a yard is seldom or never attained without persevering slaughter of the offenders in colour.

Double Feather in Fantail's Tail (*Frank Dixon*).—A double feather is not uncommon in the centre of the tail of a Fantail Pigeon. We have seen several, and bred one so ornamented last season. This double feather is less common in other Pigeons; but we have seen a Pouter cock with one. It is no recommendation, though not a disqualification in a prize list.

Castle Eden Poultry Show (*W. J. Wilton*).—It often happens that awards have to be corrected, and that prize cards are wrongly affixed. You had better write to the Judge. Our report was sent in manuscript by a private correspondent.

Silkworms (*A Seamstress*).—Unless you have a good quantity of silk reeled as required in commerce, it is useless to try to sell it; but if you have cocoons unreeled I will bid you a price for them if of good quality.—Leonard Harman, jun., *Old Catton, Norwich.*

Dividing a Stock (*A Tyro*).—There are not two queens; and if you attempt to make two stocks out of one in the manner proposed you will certainly be disappointed.

Weight of Comb (*R. A.*).—A square foot of new and clean worker comb of medium thickness weighs when empty about 3¼ ozs. The quantity of actual wax in a comb does not increase with age. The yellow dust which falls from your combs consists of Acari or mites, which prey on the pollen which they contain. We have often used comb infested with these mites, and never found them produce any injurious effects. We should not, therefore, be afraid to stock the hive with driven bees.

Bees not Using Supers (*Filburston*).—We cannot tell why your bees refused to work in the supers, unless you put them on too late, or possibly did not wrap up the glasses sufficiently to keep them warm. At any rate it is now quite too late to expect them to be occupied. We find that there is still a good deal of brood in our hives, and we presume also in yours, which it seems a great pity to destroy; on the other hand, we have little doubt that the store of honey is rapidly diminishing. There will be less risk of a quarrel if you drive the inhabitants of both hives one after the other into an empty one, and then induct the whole into the hive which they are permanently to occupy.

POULTRY MARKET.—August 18.

We are falling into the sere and yellow leaf of autumn, and the trade is becoming nominal, while the supply increases. We shall have sorry returns for some time to come.

From observations taken near London during the last forty-two years, the average day temperature of the week is 72.8°; and its night temperature 48.3°. The greatest heat was 85°, on the 1st, 1843; and the lowest cold 31°, on the 25th, 1851. The greatest fall of rain was 1.50 inch.

A SECOND VISIT TO THE SEEND ROSERY.

ANCIENT readers of "our Journal," so ancient as to have read the number for August 21, 1866, will perhaps remember that I had then recently paid a visit to Mr. Ambrose Awdry's Rosery at Seend, Wilts. I say ancient readers, for three years since seems in this very varying, rapidly-changing age of ours quite a long space of time. I give three years as the period a man may be remembered; if he is recollected longer, rely upon it he must have done something very good, or very bad, he must at least have built a church or—burnt one down.

That visit of mine to Seend in the summer of 1866 was a visit made in company with many; there were forty of us, but this time it was a party of four. And this brings me to remark upon the proportion of happiness to be had in large parties or small. There was something in Thackeray's advice as to social pleasure when he said, "If you wish to enjoy yourself, never go beyond the leg of mutton," which said muttony leg he meant to represent—to symbolise, a small entertainment. But I, for my part, would lay down no rigid rule. Does it not come to this—in a large party the pleasure is diffused, in a small one it is condensed? Then the pleasure is diverse; among a large number my happiness is partly in looking on at the happiness of others, in hearing the light laughter, in seeing the bright smiles. In a party of forty there are sure to be young people, and they are sure to be light-hearted, and light-heartedness is pleasant to look at, and is catching too. Young people make us feel young again, and how beautiful is mere youth! it is the very bloom on the Plum, soon to be rubbed off by the world's wear; but—— no more of this. In a small party of like minds and like tastes there will be at any rate more close talk, more of head to head, and of heart to heart. The last time I was at Seend there were many ladies tripping from Rose to Rose; this time no ladies, but four, and with our host five, male rosarians. As we by chance met in the same railway carriage, I could see there was written upon the face of each, "I mean to be happy to-day." Then the day was just the thing, neither frying to Rose and rosarian, nor showery, but just a little air going, and alternate gleam and cloud. All five were rosarians, four up to boiling-point and the fifth just simmering.

But here is Seend Station; a climb up the hill follows, and then "The Bell," a really old-fashioned, neat, and very clean village inn, with a twistabout staircase, and tidy little rooms around. I almost expected to find old Izaak Walton with his fishing-rods in the corner of the room, he over a frugal lunch deep in talk with "Venator and Piscator" about "a fine fresh May morning," and the singing birds, "those little nimble musicians of the air that warble forth their curious ditties with which nature hath furnished them to the shame of art." And the meal over, I expected to hear old Izaak say, "And now, scholar, I think it will be time to repair our angle rods." At any rate, had I slept at "The Bell," I have no doubt I should have found, as Izaak did at his inn, that "the sheets smelt of Lavender." But a truce to fancy; there, in the village inn's best room, was our luncheon; and the better to enjoy a long visit to the Roses, we lunched well—a good plan, gentle reader, for we are in the body yet. We ate Strawberries so good this bad season, that I was inclined to say with Dr. Boteler, "Doubtless God could have made a better berry, but doubtless God never did."

Lunch over, then away down the village street to Mr. Awdry's fruit garden, where old George, the gardener, awaited us. Old George, his master's right-hand—I must put him in print—there he is before me, a 6-foot man, white-hatted and white-headed, with a decided military look and bearing, which stooping all his life to cultivate mother earth had not altered. Well done, old George! Here we find an orchard house in full swing, Grapes and wall fruit looking equally well; then we spied over and walked through a plot of pyramid Pears in perfect health, Crasannes, Beurré d'Amanlis, Williams's Bon Chrétien, &c., all bearing abundantly. Coming to the Strawberries within this walled garden old George confided to me that he found that Dr. Hogg did not do on a hill, but that he does admirably in a valley; perhaps that is because the real Doctor, our Doctor, lives and does well in the valley of Pimlico!

Marking the exceeding fruitfulness of everything save Strawberries, we pass on to reach, *viâ* the pretty old church, the Rosery. How beautiful is the view of the rich valley, and beyond, our Wiltshire Downs! When I looked on that valley I thought of what Charles V. said of the city of Florence, "It was too pleasant to be looked on, but only on holidays." The striking feature of Mr. Awdry's Rosery is its being among green fields; itself, until a few years since, one of them. And in England, as we have so much green, a large Rose garden is very telling in a green setting. Entering I find as before a silver frame to the Rose picture in the shape of a fence lined with Félicité Perpétuée, now in all its blooming glory. Since my last visit Mr. Awdry had entirely given up standards; every Rose is now dwarf, and worked on the Manetti. This lowering of the flowers gave a still greater resemblance to a carpet, with its bright squares divided by green lines—viz., grass paths. We passed on with the master, who was as proud and happy as a mother showing her nursery darlings, and as to old George of the white hat, he seemed like head nurse; but which was happier, or prouder of the Rosery, master or man, I scarcely know, but certainly old George was as happy as if every Rose was his own. The bushes (we may talk again of Rose bushes now that they are budded below the soil), are in rows, and in each row six together of the same colour, and many sixes make up a whole row. The size of the Rosery and the size of the blooms both struck me. There was Pierre Notting in its dark glory, Mr. Awdry's and old George's special favourite, the latter remarking, "It does smell *so* sweet." There were Céline Forestier grown larger than usual, and Charles Lefebvre, Senateur Vaisse, and Comtesse Cécile de Chabrillant, numerous, and holding their proper place—namely, the first; John Hopper strong and good; while

Jules Margottin was, as usual, always good—if I could only have one Rose, let it be Jules, wood, leaf, flower so vigorous—Madame Vidot, best of light Hybrid Perpetuals; and William Griffiths, the firmest and living longest as a cut flower. But who can sufficiently praise Louis XIV., Lord Macaulay, Prince Camille de Rohan, and dozens of others? Only one first-class Rose I was unable to find, and that was Alfred Colomb. There are also two Roses not first-class, and yet I hold they catch the eye more than any others; these are Eugène Appert and Empereur de Maroc. What a pity it is that they are not so perfect as Charles Lefebvre.

In this Rosery Strawberries are grown along the sides of the paths; although this has been in North Wilts a bad season, yet those at Seend were the best I had tasted. Sir Harry was good, but Dr. Hogg was better. Here were we five cutting buds, eating Strawberries, chatting, laughing, talking Rose talk; indeed, inclined to take a rosy view of things in general. Some of us were representative men; our host represented one of our oldest and most numerous Wilts families, he its head; then another was an Anglo-Indian, a third an Anglo-Frenchman, and I represented, however humbly, "our Journal." The ground of the Rosery slopes gently to the south, and a summer-house is at its upper end. Hither retiring to sort my buds, I could also view in its completeness this charming Rose garden, the white border, the pillars and arches along and across the paths, the Rose squares within them, and the rich-coloured loam the ground colour. Then bear in mind the scenery beyond and the dry bracing North Wilts air. One circumstance makes ours a prettier part of England than some others, for almost all the land is pasture, ours being a dairy country.

Satisfied but not satiated, we next bent our steps to the old church. Wonderful is the attractive power over all travellers of these old churches, scattered like earthly stars all over England. The builder of Seend church was a clothier, as two pair of shears cut in the arch of one of its windows reveal to us. A wealthy liberal clothier built the sacred fane, bringing to mind the grand days of West of England cloth manufacture, before the north with its coal, and, mayhap, its greater energy beat us. But although the cloth trade of Wiltshire is not what it once was, yet the county owes much to it, as said an old Wiltshire man, the owner of thousands of its broad acres, "Wiltshire aristocracy is made from cloth." What a pity that trade and landowning are ever thought antagonistic, for each helps the other. Peeping about church and churchyard, we find our good host's family burying place, which, engirdled by an iron railing, he, like a good rosarian, has planted with the choicest and most frequent-blooming Roses, and there I saw Alfred Colomb in all his glory. A nice thought was this, giving the fairest flowers to those best loved.

Back to "The Bell," for dinner, where pleasant chat made the time seem too short, and that last train (Why was it not late as well as last?) will soon, our watches tell us, come groaning and panting to the station.

Thus passed a happy day, and which visit did I enjoy most? Well, comparisons are odious, but I must say, if I want to enjoy Roses, the best plan is to go with but few friends, and those gentlemen, for *two* kinds of flowers are apt to confuse the mind. These thoughts strike me, how every true lover of floriculture increases not only his own happiness, but that of his friends, and what a pure happiness flowers give to those who love them. Here was my host made happy through much of the year by his Roses, and adding to the happiness of others by opening his rosery to them. One sad thought only during this day that did one good, crossed my mind—it will be my last visit to the Seend Rosery, for part of the Roses will be removed to Bath, the rest sold, and the green turf will again, as it had done for centuries, reign where for a few years the queen of flowers has reigned supreme. But who will not wish Mr. Awdry may have as much happiness with his Roses in Bath, as he has had with his Roses in Seend?—Wiltshire Rector.

THE EARLY ROSE POTATO.

Having purchased a pound of the above Potatoes from Messrs. James Carter & Co. I set them in March in the following manner:—I cut them into sixty-five pieces, getting an eye to almost every set; I believe every one of them germinated. I placed them in a row covered with about 2 inches of soil; when the tops were about 6 inches high I drew about two more inches of soil over the root. The soil is of a light sandy character. Thinking they were a first early Potato I cooked 2 lbs. in the middle of June; they were sad, very white, and sweet. I took up the remainder of the crop on the 16th of August, and have carefully weighed them. The 1 lb. of seed has produced 44 lbs., and I believe that had the whole of the sets been in equally favourable positions, I should have had 60 lbs. at least. I may say that in size and shape, the sets were something like a Filbert. One of these sets produced five Potatoes weighing 1¾ lbs. There are at least twenty that weigh half a pound each. I cooked some more yesterday (August 17th), and found them splendid. I never tasted anything to equal them.—A Subscriber, *Nottingham*.

NOTES OF NORTHERN PRODUCTIONS.

I perceive it would never do for Mr. Bréhaut and myself to have a Peach house in common, for we should both be wanting to eat the same fruit. I quite agree with him that Early Rivers is by far the best early Peach we have. It ripened with me in the middle of July in a perfectly cool house with an open door and open ventilators within 6 feet of it. A tree in the heated house ripened on the 10th of June.

In this house I can add from 30° to 40° to the external temperature, but in practice I use just enough to keep frost out at night, and with sunshine to allow 80°. My house is divided into three compartments, respectively of 40 feet, 30 feet, and 50 feet in length; the first is heated both above and below the surface, the middle only below, and the west end is unheated, though it has the pipes laid for use if wanted. The form of the house is a lean-to with a hip-roof, having 7-feet and 14-feet rafters, and the pitch such as to have the midday sun perpendicular to the glass on the 15th of April. The back wall is covered with Peach trees *en cordon oblique*; all the rest of the trees are in pots, and stand on the slate bed beneath which the hot-water pipes run. The potted trees were packed closely in the cold end, and kept dry till the middle of January; the ventilators, which are very large, being for the most part always open, those at the top invariably so. The early Peaches were showing blossom early in January, and I feared I should be obliged to light the fire sooner than I wished; however, the trees were not moved into the other compartments till the middle of the month, the earliest sorts going to the warm end. The bottom heat was allowed to work for ten days, with abundant ventilation, before any surface heat was given; by that time the blossom was well out; and here I may remark, that both this year and last Early Beatrice was a fortnight later in opening its flowers than any other tree in the house. In the middle compartment bottom heat alone was given, and the cold end was still very crowded with potted trees, but kept as cool as possible. All the trees set most abundantly, but as there were no insects about I used a brush to fertilise, and, perhaps, the quantity of pollen in the brush, which I kept dry, may have made up for the cloudiness of the season; but on this point I have my doubts, because the few trees I have outside on the walls have very fair crops, and I left them entirely to nature. Apricots outside failed completely, but then we had frost every night in June, and often it was severe, so severe as to take the leaves off the Apple trees, and to these June frosts I attribute the failure of the Apricot crop.

To return to the Peaches. The earliest to ripen were Early Beatrice and Early Louise simultaneously on the 3rd of June; of the two, Early Louise is the larger, and for in-door work is, no doubt, the better; but that remarkable property of late blossoming seems to mark Early Beatrice as the sort for us northerns out of doors; at any rate I have worked some for the purpose of putting into my neighbours' gardens, and by this time next year I hope we shall know how far it will answer. The next after these two very early Peaches was Early Rivers, on June 16th; then Early Silver, Hales' Early, followed closely by Early York, Rivers' Early York, and Early Crawford. Of these Hales' Early is a very large handsome Peach with little flavour; Early Silver and Rivers's Early York very fine. Early Alfred and Early Albert came next, and then Early Grosse Mignonne and the ordinary varieties.

The warm compartment had fresh trees brought into it to take the place of those whose crops were gathered, and it has now (August 17th), a few trees, mostly Nectarines, of its third set ripening fruit. By this method of shifting the potted trees, it is quite amazing to see the quantity of fruit a small house can be made to produce. The trees are hardened-off and plunged in a warm piece of ground, and as they have plenty

of space given them outside, the ground they cover is very considerable, and they look as if it were impossible for them to have occupied so small a space in winter.

The enormous Susquehanna Peach of last year might have been the result of allowing a vigorous young tree to throw all its strength into two Peaches, so this year I left a numerous crop on, and therefore a very heavy one, for the Peaches are again very large, though of course not so large as those of last year. I have just weighed and measured two that were allowed to hang from the same eye, one weighs 9 ozs., the other 8 ozs., and the girth of the larger is nearly 11 inches. These are just about the usual size of the rest of the crop. This Peach is a very good one of the yellow-fleshed class, quite as good but much larger than Exquisite, which has always stood alongside of it.

Another magnificent Peach is Mr. Rivers's Nectarine Peach, the average weight being more than 8 ozs., and the flavour peculiar and exquisite. Princess of Wales is nearly ripe, and is again of the large size of last year. As this is a very high-flavoured Peach it ought to be in every collection. Lord Palmerston and Lady Palmerston are far from ripe, and have been in the middle compartment since January. They are already very large, and in due course I hope to be able to report further upon their qualities.

Before ending I have a few words to say about the Nectarines. Rivers's Stanwick Elruge was the first to ripen, and is very fine. The medium-sized Pine Apple is far superior to its ancestor Pitmaston both in size and quality. Albert Victor is new in texture and flavour, being a melting Nectarine—so much so, that two ladies yesterday thought they were eating a Peach, and one of them is no novice in Peach-eating. Victoria is always good and a most abundant bearer, and I may add a most useful one to have in a house, from the enormous quantity of pollen it produces. Albert (or No. 8) is a very grand one, weighing 6 ozs., and exactly like the Stanwick in flavour; like it, too, it is apt to crack. Prince of Wales Nectarine I do not think worth its room, though very beautiful to look at.

Such is my experience of the season so far as these new varieties are concerned; and I should advise all Peach-growers to have Early Louise, Early Rivers, Early Silver, Rivers's Early York, Early Alfred, Nectarine Peach, and Princess of Wales. These give a succession and a wonderful variety of flavour. I see I have forgotten to mention Alexandra Noblesse. It is just like the old Noblesse in flavour, but larger and more vigorous, and from having glands it is not liable to mildew like the old variety. It must also go into the above list; and when Grosse Mignonne is added to it, along with the late varieties Lord and Lady Palmerston, I do not know that any others need be added, unless it be one which I had from Mr. Rivers under the name of Malta, but which turned out very superior to that variety.

We have had a most inclement season in our district; cold, parching, easterly winds all through June and for a great part of July blighted all the trees. Strawberries, which usually grow very large here, were misshapen, and for us a bad crop.

I am glad to see attention drawn to that most admirable variety of Strawberry Vicomtesse Héricart de Thury; it fully deserves all the praise given to it. It is not the same as Prince Imperial, and as I have that variety from Sawbridgeworth I take it for granted the difference is in the varieties, and that they ought not to be considered synonymous. Dr. Hogg was one of the few that defied the weather, and I think it the best dessert fruit grown. Rivers's Eliza also did very well and grew to a large size. Frogmore Late Pine failed completely. Sir Charles Napier surprised me by being as good as ever.—W. Kingsley.

PELARGONIUM BAYARD.

Your correspondent "Sans peur," at page 117, speaks of the above bedding Pelargonium in laudatory terms. As I have grown it for two seasons both as a pot plant and in a mass in a bed, I seek to express my opinion respecting its merits. I unhesitatingly pronounce it the best Pelargonium at present in commerce, and in my judgment of it I am supported by many eminent horticulturists. I have a bed of it in a small geometric flower garden adjoining my own cottage, and from the time of planting until now it has been the object of general admiration. Bayard is one of the best varieties of Mr. Pearson's raising sent out last year; but in his trial grounds, about two months ago, I saw several others which then promised to eclipse Bayard, notwithstanding its "brilliant beauty." The most conspicuous were William Thomson and Douglas Pearson; the former does honour to the name it bears.—Quintin Read, *Pleasley Vale Gardens, Mansfield.*

RUST ON GRAPES.

I lately saw a curious instance of rusted Grapes, one or two facts in connection with which are worthy of note. The vinery in which these Grapes are growing is a small lean-to, ventilated by means of sliding sashes in front, and on the upper half of the roof by moveable lights, which slide down and are pulled up by ropes. The house contains two Vines managed on the extension system; one is a Black Hamburgh and the other a Black Prince. Both are carrying a heavy crop, both are alike vigorous, and here the similarity ceases; for with but one slight exception the foliage and fruit of the Black Prince are perfectly healthy and free from any disease, while the Black Hamburgh is diseased both in fruit and foliage. The backs or under sides of all the leaves developed in the earlier stages of its growth are covered with warts, and almost the whole of the fruit is regularly encrusted with rust, and yet although so severely affected, the fruit has continued to swell; but so unsightly is the effect produced by the rust that hardly a bunch will be fit to send to table. The foliage of the sub-laterals is perfectly healthy, so that it is quite evident the diseased foliage does not arise from any debility of the Vine, but from external causes. The disease of the foliage is doubtless caused by its being subjected to the action of a close warm temperature saturated with moisture, and that of the fruit in this case by a sudden change in the temperature of the house during setting, in consequence of which the cuticle (peculiarly sensitive at that period of its growth) became affected, and the rust has gradually spread till it has almost covered the entire surface of the berries. Slight traces of rust visible on a few berries of Black Prince at the top of the house, right under the part at which the cold air must have entered, tend to lead one to the above conclusion, as with this slight exception the Black Prince Vine is entirely free from disease; its tougher cuticle and more hardy constitution apparently enabling it to withstand the effects of a treatment which has proved so fatal to the crop of its more delicate neighbour.—Edward Luckhurst, *Egerton House Gardens, Kent.*

YUCCAS, AND THEIR FLOWERING.

Amongst the results of the dry summer of 1868 the extraordinary blooming of trees this season is not the least remarkable. The Paulownia imperialis bloomed where it had never bloomed before; Edwardsia microphylla and other greenhouse plants which had withstood the winter, also flowered out of doors; while the flowering of the Elms and other trees showed the effects of the hot, dry autumn. To a like cause I attribute the unusual number of blooms we have at the present time (the end of July) upon our Yuccas. The tendency of this plant to push up its flower-spikes at all seasons, often leads to the destruction of its blooms when they appear late in autumn. It often happens, after a fine summer, that a great number are sacrificed in this way, and many were so destroyed last winter; but it would appear that others were not so matured in the bud as to expand in the autumn, and have done so now. The exceeding beauty of these excites the admiration of everyone; no flower spike of any other plant that I am acquainted with can at all compare with that of the Yucca in elegance of shape and density of bloom, and a full-grown spike is a load for anyone. Besides, the plant presents a tropical aspect, when thriving has a sturdy appearance peculiar to itself, and when a number of plants are in flower at one time the effect is very striking. We have now upwards of fifty of the larger species in bloom, varying in height from 5 feet to nearly 11 feet, most of them being about 7 feet high, and more than half this height consists of bloom. The species or varieties seem to run into each other so imperceptibly that it is difficult, in fact almost impossible, to distinguish between them, more especially as two portions of the same plant often present different features. However, as the specific names, gloriosa, recurva, aloifolia, acuminata, and some others, are used, it is well to retain them. Y. filamentosa is of humbler growth, and flowers more freely than the abovenamed, but it is no hardier. The variegated forms of Yucca are not yet sufficiently plentiful to be much used out of doors, excepting in some particular spot, and where, probably, their flowers are not desired.

The soil suited to the Yucca has been variously described, some considering lime and other calcareous matters injurious,

but here it would be difficult to find a place where these substances naturally exist in greater abundance than the border where the Yuccas are growing. The substratum is an open stone shatter, which can be penetrated by the roots of trees, and is much liked by them, and, no doubt, by those of the Yuccas as well. These, with Irises and some other plants, occupy a border by the side of a terrace wall, fully exposed to the south, and sheltered on all the other sides. Many of the Yuccas are of great age, and have occupied their present site many years; but those who plant Yuccas for effect must not expect them to bloom like Pelargoniums, immediately after planting; however, when the situation and season are favourable, they will be rewarded by spikes of bloom sooner than they expect.—J. Ronson.

CAMPANULA PYRAMIDALIS CULTURE.

This fine old plant seems for many years to have been under a cloud, so seldom has it been seen in fashionable quarters; but as it has claims which will not be set aside, it is almost certain that it will soon come up again with almost the freshness of a novelty, and gardeners may successively find out that two or three plants tenfold more worthless might with advantage be transferred from the greenhouse to the rubbish heap, to make room for the steeple Bellflower of olden times.

Although it has been treated with coldness by many of those who ought to have known better, it has been all along a favourite window plant with amateur cultivators, and I can say without fear of contradiction, that no other plant grown combines in itself so many of the qualities essential to plants suitable for window decoration. In the first place it is strikingly handsome; it is no minute beauty which we must bend over, and after due examination pronounce pretty, but it levies the tribute of admiration at first sight from all who see it. It is not, in general, thought "the correct thing" to stare in at people's windows; but when they contain one or more of these blue pyramids, 8 or 9 feet high, there is no help for it. It is also easy of cultivation, not subject to the attacks of vermin, and, which is a great desideratum in window plants, it does not obstruct much light. As an example of what can be done with it as such, I was taken a few days ago to see two plants grown, and at present flowering in the windows of a large public school. They had been in flower for nearly two months, and seemed likely to continue so for a month longer. One of them was 8½, the other 9 feet in height, and their cultivator, on my remarking that they were only in 8-inch pots, informed me that in general he found every inch in the diameter of the pot counted a foot in the height of the flower spike; thus, if the last shift was into 6, 8, or 10-inch pots, the plants would throw up stems 6, 8, or 10 feet high.

The reason why this Campanula is so seldom grown, will most likely be found in the fact that, as things go, it is rather a slow subject. In these days, when Vines have to carry heavy crops at eighteen months old, and when the old saying, that "He who plants Pears plants for his heirs," has become absolute nonsense, it seems folly to expect that any considerable number of people could be found who would patiently wait nearly three years for a spike of Blue-bells, however grand; but if we begin at the beginning, and raise our own plants, we must do so.

Campanula pyramidalis is generally propagated either by seed—and seedlings make the best plants—or by division of the old plants after flowering. The seeds should be sown in heat about the middle of March in light sandy soil, and merely covered with a dusting of fine peat and silver sand. When large enough to be handled, prick out the seedlings singly in small pots, and continue them in heat until the pots are filled with roots; afterwards place the plants in a cold frame or pit, giving small shifts when necessary, the last for the season taking place not later than the beginning of August. For this use a rich but porous compost, and take care to insure perfect drainage. During winter the plants should be kept rather dry, in any place where damp rather than frost can be guarded against, and for that purpose the sill of a large, light window is all that can be desired. Receiving the same treatment during the second summer, with the addition of frequent manure waterings, next August should find them in 8 or 10-inch pots, leaving room for one more shift in spring, just before the flower stems begin to rise. After the roots have penetrated this, and all the time the plants are in flower, continue to give rather weak guano or other manure water every second day, and soon the great blue Gothic spires, which more than sufficiently repay all these little attentions, will be worth looking at.

After the flowers are past, cut the stems over, and in the following spring, when growth has begun, divide the old stools into as many plants as there are growing points. Treated the same as seedlings, these will flower in the second season, but I have always found plants from seed the freest-growing.

Of course plants are to be bought if we know where to purchase them, and thus much trouble is saved; but when once a beginning is made, and a dozen plants or so are raised every year, they form a succession, and the weary waiting for more than two years, which so harasses the imagination, is lost sight of.

The white variety is scarcely so robust, but when grown along with the blue is equally ornamental. As plants for the mixed or herbaceous border, these Campanulas are very fine, although there they have not the same stately dimensions nor delicate colours which characterise them under glass. A warm sheltered border, backed by a wall or shrubbery, is the situation which suits them best.—Ayrshire Gardener.

THE QUINCE STOCK.

I believe more men fail with the Pear upon the Quince than upon the Pear, for the simple reason that they fail to perceive a very different mode of treatment is necessary for the one than the other. It is not uncommon to hear a gardener say, "Well, I have discarded the Quince stock as useless. I planted a number of them with a number worked upon the Pear side by side; they all received the same treatment, and the end of it is, I would not see them about the place!" Now this is exactly what I find fault with. Such gardeners belong to the same class as those quack doctors, who will not be loath to make you believe that they can give a box of pills, or some other trash, which will cure humanity of all the ills to which it is heir. Let the gardener who plants Pears upon the Quince understand that he has a very different subject to treat than the Pear upon the Pear. The latter is in its natural and most congenial position; the former is, as it were, a sojourner in a foreign land. The former is sure to succeed if the soil and climate suit, if root-pruning is attended to regularly, and the tree kept free from its various and many enemies. But then there are many soils and situations where the Pear will not succeed upon the Pear unless deep artificial borders are made.

The west of Scotland, as I formerly said, is one of these, the average depth of soil in many of its districts not being more than 12 or 15 inches, while close beneath this lies a stratum of gravel highly impregnated with iron. Now I will ask any reasonable man, Will the Pear stock succeed in such a position, seeing that it must be utterly impossible to keep the roots from entering this bad substratum, even suppose we had the power of root-pruning once a-month? It may be possible for a few years, but only for a few. Almost as soon as the tree began to bear, disease, canker, and death would be draining its very life blood out at every leaf. Another enemy we here have to contend against is wet; and I believe and know from experience that the Quince is a better resister of damp than the Pear, where properly managed.

I have here about five dozen Pears on the Quince and five dozen on the Pear. They are open for inspection to every inquirer. They are five and six years of age, and I have no hesitation in decidedly affirming that those upon the Quince are the best trees, produce the best wood yearly, which ripens as hard and brown as a Vine, and, to add to all, their appearance is much more handsome; and from what I have seen elsewhere, when they arrive at full bearing, the Quince will prove the more profitable investment of the two.

Those worked upon the Pear will be root-pruned this year in autumn, which will be the second time during their five years' existence, and in some cases it will have been oftener.

Those upon the Quince we manage in quite a different way. Every year, or at least every two years, we cut a trench round each plant, being as careful as possible not to injure one of the roots. We often remove the soil away from them to a little extent, to enable us to get the fresh materials placed as near the body of the roots as possible. This being done, we introduce a fresh mixture of richly manured loam, placing the roots which were laid bare into their position as we proceed. We also proceed to uncover the upper surface all over the extent of the plant to the depth of 3 or 4 inches, or until we find that we are coming into contact with the upper roots. Into this we

place 3 inches of good rotten dung, covering the whole over with an inch or two of soil. Now, no one can deny but that there is as little trouble in doing this as in root-pruning; and if this be the case, and the after-results prove better, the advantage entirely lies with the Quince stock.

Our reasons for proceeding upon these principles with the Pear upon the Quince are as follows:—The Quince, as every one knows, is a weakly grower compared to the Pear, therefore by placing the Pear upon it we are imposing a burden greater than it can bear in a natural way.

It is impossible that the Quince can do the work required of it by the Pear without assistance, and it is still more wonderful that so many intelligent and able gardeners should expect it to do so.—James M'Millan (*The Gardener*).

FRUIT-GROWING AT MR. DANCER'S, LITTLE SUTTON, CHISWICK.

A more pleasing walk than that which I have just finished, or a more splendid sight in fruit than that which I have just seen in Mr. Francis Dancer's great market fruit garden at Chiswick, cannot well be imagined. Fruits—good fruits—are at all times pleasant to look upon, but when seen as they are grown in Mr. Dancer's establishment, which was so ably and fully noticed by "Leo" in the last two volumes, they are something more than that.

Although the present is not quite such an abundant fruit season as the last—indeed, in many districts the crops are painfully short, and dire complaints reach me from all quarters—Mr. Dancer seems to have fared well, and with few exceptions, principally amongst the Plums, his trees are again as densely laden as ever. The lines upon lines of trees of Denyer's Victoria Plum bending beneath their heavy freight, every little twig having to be supported by sturdy props, are really a grand sight. The enormous weight of fruit borne by these trees is very astonishing, and all the fruit are of large size and splendid quality. This Victoria is the Plum of the season, heavily cropped everywhere, yet nowhere have I seen it so fine as here, and this is attributed to the high cultivation of the soil, which is heavily manured for vegetables. The trees grow very vigorously, and are left unpruned, so that the strength of the tree is directed towards the fruit instead of the production of mere shoots, as would be the case if they were pruned closely back. The other varieties of Plums cultivated by Mr. Dancer are not this season so heavily laden, although Mr. Dancer's favourite variety, Mitchelson's, is yielding well, and there has been a fair sprinkling of that most excellent market Plum, Gisborne's, which cannot be too highly recommended. It commands a high price in all its stages. It is one of the best kinds for bottling green, and makes an excellent preserve when ripe. Plums this season, like Peaches, had their blossoms destroyed by the cold, cutting winds in spring.

Another pretty sight here is a long line of dwarf Beurré d'Amanlis Pears on the Quince stock, very heavily laden with large and beautiful fruit. This is a fine-looking variety of Pear and a great bearer, of fair average quality. It is not, however, so good in quality, nor so well known in market as Williams's Bon Chrétien, which comes into use at the same time, but the heaviness of the crop generally produced makes it not an unprofitable sort to grow. Of other Pears bearing good crops, cultivated extensively by Mr. Dancer, may be mentioned Jersey Gratioli, a really good market variety; Louise Bonne of Jersey, the very best Pear in cultivation, taking all points into consideration; Aston Town, a rather small sort, but a prodigious bearer; Beurré de Capiaumont, Beurré Bosc, and several others.

The grandest sight here, however, and one which all fruit cultivators ought to have seen (the fruit will be gathered ere this is printed), is the crop of Small's Admirable and Lord Suffield Apples, two of the finest early kitchen Apples in cultivation. It is very extraordinary and very splendid. There may be somewhat over an acre planted with these trees, in lines of fifties or so, and about 10 feet between the trees in the lines. They are dwarf bush trees, like good-sized Gooseberry bushes, and are bearing fruit nearly as abundantly; each fruit a specimen—clear, large, fine, and nearly uniform in size. Some lines of these trees are grafted on the English Paradise, and some on the Crab stock as received from Mr. Rivers, and a more capital illustration of the superiority of the one stock over the other could not be desired. Those worked on the Paradise are not nearly so large; they are, however, bearing nearly double the quantity of fruit, and further, the fruit is finer, clearer, and larger. The difference is very marked in every way; the strongest and the most vigorous trees bearing not only the smallest quantity, but the smallest fruit, and these are on the Crab stock. Who would use the Crab stock for Apples, excepting for large rampant standard orchard trees, after seeing such superior results obtained by the use of the Paradise under exactly the same conditions? These dwarf fruiting trees are much preferred by Mr. Dancer to the tall orchard standards generally to be seen in market gardens; they produce fruit more abundantly, more regularly; they are more easily attended to, and the crop is more easily gathered, which last is no small consideration, the expense and the danger in gathering fruit on tall trees being very great. Further, the fruit on the dwarf trees are not so liable to damage and loss as those on tall ones, which are at the mercy of every little gale.

Amongst other Apples bearing profusely here this season may be mentioned a variety named Barchard's Pippin, a late sort, in the way of King of the Pippins, and of very good quality. It is a clean and vigorous grower, and always a very determined bearer, consequently a valuable market sort. Manks Codlin also looked well. It must, however, be very vexing to Mr. Dancer to see acres of his beautiful orchards being felled to the ground for the erection of ricketty take-in buildings and unprofitable railways. Cox's Orange Pippin is also bearing enormously—some hundreds of bushels of fine fruit. The little Yellow Ingestrie Pippin is also greatly cultivated, and found very profitable; also the Golden Noble, Cox's Pomona, &c.

The practice here followed in fruit culture is to grow the trees well, to plant thickly, so as to cover the ground quickly, to obtain the fruit as near the ground as possible, and to leave pruning and pinching alone, doing nothing further than shortening the ends of some long straggling shoots, and thinning the branches where too thick, so as to allow plenty of light and air to every portion of the tree. That it is successful is best determined by the results, the like of which I have never seen.—Archambaud.

HOLLYHOCK CULTURE.

This noble autumn-flowering plant is very much neglected being interspersed amongst other plants in shrubbery borders but if planted in rows in rich, well-drained soil, so as to form a background to a neat border, it would well repay the grower with a splendid display of bloom.

It is propagated by cuttings, single eyes, and seeds. The cuttings should be taken off the plants early in spring, and do best dibbled in light soil in a frame where a slight bottom heat can be given. When well rooted take them carefully up, and plant them in 6-inch pots, using one-half rich loam, one-fourth well-decayed manure, and one-fourth leaf mould, with a good dash of silver sand, all well mixed together. Remove the plants to a cool frame for a short time to harden-off previous to planting them out in the open ground. This mode of propagation has the advantage of affording a succession of blooms after the old plants have succumbed, and though the spikes are not so fine in the first season as those on old plants, they will fully equal them the next.

The next mode of propagation is by single eyes taken off in July and August, and inserted in light soil, in pans well drained, and plunged in a frame in tan or leaves, so as to have the assistance of a little bottom heat, giving air as required. When the eyes have made a little growth, and are sufficiently rooted, pot the young plants singly in 3-inch pots, replace them in a close frame for a few weeks, and when the pots become full of roots another shift will be required, this time into 6-inch pots, using soil as directed for cuttings. At this stage the plants may be placed in a cool pit or frame to protect them through the winter, admitting plenty of air on all favourable opportunities. They will be ready for the open ground in spring.

The third method of propagation is by seeds, which should be gathered early in the autumn from the most double blooms of the finest shape and colour, and sown in pans, giving the seedlings the same treatment throughout as plants from single eyes

Plants established in the ground, if planted in well-drained soil, may be left there all the winter, merely protecting them with a covering of coal ashes.

I have practised the mode of culture I have described, and

found it most satisfactory. I have many plants measuring upwards of 12 feet high, and covered with blooms from the base to the apex.—HENRY C. OGLE, *Welwyn*.

AMONG THE ROSES.

NOT young love at his pranks, but old, sober, staid affection, which never tires of the objects of its love; and as I had lately an opportunity of paying a visit to two of the most celebrated of our Rose gardens—those of Messrs. Rivers, of Sawbridgeworth, and Messrs. Paul & Son, of Cheshunt, I have deemed it well, notwithstanding the notes I have already given, to append thereto a few remarks made in company with Mr. Perry and Mr. George Paul. The former has been among Roses for many a long year until he has grown grey in the service; but he still retains all the enthusiasm of youth, mellowed, however, with the experience of age. He sees not a Venus in every new and highly praised *débutante*, but he can and does appreciate to the full extent the lovely damsels who now and then appear as brilliant stars in the train of the queen of flowers. Like his employer he loves the Rose, and rejoices over the increased and increasing favour she is receiving. Of Mr. George Paul, it is not too much to say that he is the most successful exhibitor that we have. Wherever he has appeared this year (save once), with his cut blooms, his spear has borne down all before it, and I should think he might paper his room with the first-prize cards that he has obtained. From such sources one is sure to obtain some valuable information.

It was on the principle of the "early bird getting the first worm" that I sallied out in the morning before breakfast to encounter Mr. Perry, and I do not think that Mr. Perry considered he was a foolish worm to be out so early to be caught. The morning was bright; and although in August one does not expect the flowers of June, yet in that wonderful Hertfordshire soil you may expect them if anywhere, and I did see some very fine, yea, grand blooms. And as one saw quarter after quarter of plants on the Manetti, the thought did arise, What would Rose-growing be now had it not been for the introduction of that stock by Mr. Rivers?

As we walked along, Roses were criticised and examined, and opinions compared. We very seldom disagreed in our estimates, and I now give the principal results of our little tour. Paul Verdier must be discarded, as it is nothing more than a Hybrid China. Of Adrienne Marx the same must be said. Charles Verdier, although bearing the name of an honest good rosarian, must go, as it will not open. Joséphine Beauharnais is very good, but not vigorous enough. Annie Wood is sometimes very fine, and will make a good pillar Rose. Monsieur Noman is excellent, as we all consider it; Antoine Ducher, very good and fine; Thorin, bright, but not full enough; Eugène Scribe, good; Souvenir de Monsieur Boll, very good this season; Fisher Holmes, very bright and good; Souvenir de Mons. Corval, no good; Marie Larpin, a sweet little Bourbon, a Modèle de Perfection with a better habit. Boule de Neige is a beautiful pure white; Duchesse d'Aoste, good; François Fontaine, good crimson; Ville de Lyon, good bright rose; Prince Humbert, good; Merveille d'Anjou, no marvel at all, and very flat; Aurore du Matin, not good; and Madame Alice Dureau, a very nice Rose. Coquette des Alpes is very pretty, especially when the edge of the petal is bordered; Pitord, good; Charles Lee, bright crimson, good; Thyra Hammerick, excellent; Marquise de Mortemart, good; Madame Bertha Baron, poor; Mdlle. Marie Rady, good; and Mdlle. Marguerite Dombrain, excellent. It must be remembered that Mr. Rivers is not now an exhibitor of Roses, and that these remarks do not simply apply to the exhibition table, but are a general comment on the flowers as they are.

I started by midday train for Cheshunt, and had intended to have paid Mr. Francis a visit at Hertford, but was obliged to postpone that until later in the season. Of the Old Nurseries of Messrs. Paul & Son it is needless for me to speak. They have long been famous, and their wonderful soil, well seconded as it is by the skill and experience of the present owner, tend to keep them so. Here, too, I had the advantage of a ramble through the Rose grounds with Mr. George Paul, and as we went along the following notes were made. Conspicuous among crimson Roses was Duke of Edinburgh, originated, as it is well known, at this nursery—a Rose which has improved very much since its first introduction, although then considered first-rate; it has a brilliancy quite unsurpassed—nay, I may almost say unequalled, reminding me of the blooms I saw of Napoleon III. at Vitry, but which I have never seen on that miffy Rose since. Then the constitution is so good and the habit so fine, that they add greatly to its value. I saw also here a Rose which may be valuable by-and-by, a climbing Victor Verdier. Near it was a row of the old kind, vigorous enough, but this had shoots 6 and 8 feet long, retaining the fine flower of the parent with this largely developed growth. Mr. Paul purposes growing it on and sending it out in 1870, if it still maintain its character.

Then there were Madame Caillat, good, clear bright red, and a variegated-leaved form of the same; Baroness Rothschild—and is it not a beauty?—considered justly on both sides of the Channel as the best Hybrid Perpetual of 1868; Reine du Midi, doubtful; Mrs. Bellenden Ker, one of Lacharme's white breed, like Baronne de Maynard, &c.; Mademoiselle Marie Cirodde, over-praised, it may be suitable for a pillar from its vigorous habit, but that, I believe, is all; Princess Mary of Cambridge, another of the Cheshunt Roses, and a very beautiful and useful flower; Black Prince, very dark; Camille Bernardin, excellent, especially as a garden Rose; Horace Vernet, very brilliant, although a little crenated on the edge; Madame Thérèse Levet, a very beautiful bright cherry rose, of fine form, and has made a distinguished appearance this season in Messrs. Paul's stands; François Trevye, bright scarlet, shaded with brownish crimson; Jean Lambert, a good scarlet, with open flowers, very free in autumn, and quite distinct; Victor le Bihan, good; Elie Morel, light rose, with clear pink edges, very fine; Madame Alice Dureau, a large and full globular flower; and La France, fine, and excellent for its habit and continuous blooming.

The stroll through these nurseries suggested to me the desirability of making plantations of Roses on their own roots now. It is not everybody, like my good friend Mr. Radclyffe, who can move Manetti-stocked Roses in August; but Roses in pots of most of the good kinds can now be had, and if put out at once, a season would be gained. Already the cry, "They come! they come!" is heard. Guillot has some fine new Teas; Lacharme, I am told, a fine dark Rose; and when one hears growers praise another man's productions, alas! such is human nature, you may generally conclude that there is something in it.

Why do not some of our amateur growers give us their experience of the different varieties, mentioning their soils and situations? it would be a valuable guide to others. Doubtless, they are often deterred because they think there is nothing novel in what they have to say; but facts are always novel—*i.e.*, they bear on some case or point on which light is thrown by them. If a man says his soil is heavy, and such-and-such Roses are good, I am at once, if my soil is similar, stirred up to think perhaps they would do with me too, and the fact becomes a novelty to me. So pray do not let Mr. Radclyffe, Mr. Hole, and myself, monopolise the Rose talk. I had written thus far when a note came in by post from Mr. Radclyffe, telling me he had won the two first prizes at Blandford. He says he had 150 there, and that Duke of Edinburgh, Marguerite de St. Amand, and Baron Hausmann, were among the best that he saw at the show.—D., *Deal*.

DO BIRDS EAT ALPINE STRAWBERRIES?

I OBSERVE in your last number the question, "Do Birds Eat Alpine Strawberries?" and as my experience may not be uninteresting to your correspondent "H.," I may mention that four or five years ago a couple of packets of Alpine Strawberry seed (white and red), were purchased. The seed was sown in pans in the middle of March, on a little heat; the plants when up were hardened-off, pricked out into boxes, and placed in a cold frame, and finally planted out in the end of May. A fair crop of fruit of very fine quality was the result that autumn; but by some chance the beds in which the plants were grown were not netted, and it was remarked at the time as something quite peculiar, that though the other fruit in the garden was beginning to be scarce, yet not a single Alpine was touched by the birds.

The following year, and ever since, we have had the most abundant crops of Alpines (the runners are never cut), about the first Strawberries that ripen, lasting the whole summer in the greatest profusion; and at the present moment, August 23rd, they are still going on, not a net ever having been near them, though, be it remarked, with regard to other fruit—

Gooseberries, Apples, and Pears included—were it not for the nets the birds would leave us nothing.—D. H.

PLANTS FLOWERING IN JULY.

July 3. Silene alpestris
inflata
maritima plena
Potentilla alba
Hopwoodiana
argeotea
Thymus vulgaris

WONDERS OF AN AMATEUR.

I WONDER whether any amateur read the excellent treatise in your number of May 28th, 1868, with regard to "Standard Nosegay Pelargoniums for Winter Blooming?" In my humble way, with many drawbacks, I followed the system indicated, and was rewarded by specimens of Cybister and Stella, the only Nosegays I owned, which amazed my friends and myself, and induced me to procure this summer every variety therein suggested, with a view to the winter.

I wonder whether I am lucky in having all my specimens of Lilium lancifolium roseum, in 8-inch pots, with eighteen and nineteen healthy buds and blossoms each?

I wonder whether everybody knows that the Scarlet Lobelia will flower luxuriantly, to the height of 3 feet, in 4-inch pots, in dwelling-rooms?

I wonder why Sunset and Beauty Pelargoniums—the latter, perhaps, capricious as her name—decline to grow healthily under my auspices?

I wonder why I never saw till last year Tropæolum speciosum, a hardy, tuberous, trifoliate variety, with a luxuriant habit and a carmine blossom, figured, I see, in "Paxton," just twenty years ago? It came under my notice in an old Scotch garden, and seems to luxuriate in its new quarters near Windsor. I wonder, too, why more use is not made of the Tropæolums (or Nasturtiums), for the winter-decoration of the conservatory? Sown in September they will enliven the house for two or three dull months in the winter.

I wonder whether we amateurs shall ever have a handbook, which, in addition to telling us that Cactuses, for instance, are of the Cactaceous tribe, and entering into the specific distinctions of plants and details of the history of their discovery, will inform us of their practical management? [The "Cottage Gardeners' Dictionary" does so.]

I wonder, lastly, and I do it with trembling, why, when I wrote to ask you for a plan for a bed on a grass plot, 18 feet by 3, I was met by the chilling answer that I could get a book on garden plans for 5*s.* 4*d.*? I cannot afford such a luxury. If I had asked you to recommend a nurseryman to me, I should have expected you to refer me to your advertisements; but the kind, copious, and judicious directions with which you had previously furnished me for the treatment of certain pet plants, led me to hope that such a simple thing as a plan for a ribbon-border might be within your power and will to bestow on me. [If you send a plan we will tell you how to plant it, but we cannot undertake to furnish one.]—RUSH.

DOUBLE GRAFTING.

I SEE in your Journal of August 19th, page 138, an article on the above, by some person styling himself "OBSERVER," who sends us spinning to the Romans, Chinese, and Tartars to look for evidences of double grafting from 2000 to 10,000 years ago. I do not exactly know whether these same gentlemen lived and practised grafting before the stone age, or whether Tubal Cain had appeared amongst them, yet such must have been the case, as appears from the erudition of your correspondent. I myself am half afraid that the edge tools were not so well adapted for cutting purposes as those made by Saynor in our day.

As to "OBSERVER'S" instinctively having double grafted when a boy, why I believe that, as I happened to do the same thing myself by working eight or ten sorts of Apples on one tree, only I had slyly watched my uncle doing the same thing, I think fifty-five years ago last March. In this, I think, "OBSERVER'S" instinct had the best of it. It was a wonderful performance for a boy of tender years certainly, and I am pleased it has been recorded in the columns of THE JOURNAL OF HORTICULTURE, as a stimulant to others to go and do likewise. As to the more extended sense of the subject, I may say that I have been a double-grafter "for a purpose," in a nursery point of view, more than forty years, and I know that our continental neighbours have practised the same for commercial purposes for at least the last half century, and many years ago I could buy in the French markets Pears on Quince stocks worked by the thousand for the purpose of being double grafted. And here I will say, that "OBSERVER" is wrong in recommending the Angers Quince as the best, the Portugal sort is the best and hardiest. The Angers sort here is destroyed by every hard winter. As to the Paris Quince I never heard of it before, although I have twenty-five sorts, but this just shows that I am not quite up in the stock line.

What your correspondent means by "the flourish of trumpets" that would have been made if a Frenchman had attained the same success in double grafting as "OBSERVER'S" friend

has, I am at a loss to know. And he goes on to say that Mr. Rivers has discovered an intermediate stock for double grafting Pears upon, but "OBSERVER" was not surprised to find that its name was withheld, because of the ingratitude of the present generation in not properly acknowledging all his patron's doings and sayings. Now, I am going to be more generous to "ungrateful public," as I do not care whether he is grateful or the reverse. I work for the love of the thing, and shall give the public all the assistance I can. I know he cannot get on without such fellows as I. And as I have also discovered an intermediate stock of wonderful proportions, strong as a giant and dwarf as Tom Thumb, I mean to give the public the benefit of my discovery, and let him be grateful or not as he pleases. I do not think he will be able to help himself when he gets some of my nice luscious Pears I mean to grow on our little dwarf friend for him—*i.e.*, on the Nain vort, whose action on the graft is wonderful. Such giant-growing kinds of Pear as Gilogil, Catillac, Triomphe de Jodoigne, Jargonelle, Uvedale's St. Germain, &c., are reduced to prolific dwarf bushes, which bear wonderfully. And the seedlings of this little tree come true, and can be grafted at once, or may be first worked upon the Quince, and then double grafted as may seem best; only it does not matter much as regards their dwarfing nature whether they are double worked or not, but trees worked first upon the Quince generally give better flavoured fruit. This is especially the case in dry seasons, in wet ones the difference of flavour is not so apparent.

With respect to double grafting the Apple, I have for some years worked Manks Codlin, Keswick Codlin, Downton Pippin, and several other dwarf-growing, free-bearing kinds, and then regrafted them with other large shy bearers; the result has generally been good. But all this double work is set aside by my Pommier de Paradis stock, which has the merit of growing well, dwarfing the trees worked upon it, rendering them at the same time more prolific and better flavoured. No one else seems to possess this fine stock, as all the examples brought to a comparison with it have proved not to be anything like it, nor so valuable in so many points of view.

The last clause of "OBSERVER" is quite correct, and has been a subject of investigation for a number of years by many pomologists, &c.; and it is not looked upon as in any way chimerical, but, on the contrary, as a well-known matter of fact, that all fruits are either improved or deteriorated by the kind of stock they are worked upon—for instance, the Apricot, which we generally work upon Plum stocks, is thereby improved in size, flavour, and quality, whilst the same worked upon stocks obtained by sowing Apricot stones is generally deteriorated in size, quality, and bearing. The same holds good with many sorts of Peaches and Nectarines budded upon Almond stocks, whilst, on the contrary, these are again improved by being budded on the Plum. This is a fact that I myself have proved over and over again many years ago, and to those conversant with these matters it is well known that even the very kernels of Apricots and Peaches are affected by the kind of stock the trees have grown on. The subject, therefore, of stocks is one that cannot be compassed by the intelligence of any one individual, nor by any one generation of men. It is one of those mysterious chemical subjects, like the extraction of many colours by one plant, say, Tropæolum tricolorum, out of the same portion of earth, that almost bids defiance to man's ingenuity. It is, therefore, a work of generations to solve this influence of the stock upon the graft, and *vice versâ*. —JOHN SCOTT.

PAPERS READ AT THE HORTICULTURAL CONGRESS AT MANCHESTER.

REMARKS AND EXPERIMENTS ON THE APPLICATION OF WATER TO THE ROOTS OF PLANTS

GROWING UNDER GLASS.

PLANTS, like human beings, breathe, digest, and perspire. These important functions being principally performed by the leaves, it is a certain and just conclusion that whatever treatment promotes the healthy and free action of these organs, does a proportionate amount of good to the plant. Cleanliness, a pure atmosphere, and a regular and suitable temperature, with a proper amount of light, may be regarded as the leading conditions requisite for healthy vegetation; but although perfection in plant-growth depends so much upon the due performance of the functions of the leaves, yet there is a prior consideration—viz., the roots of the plants. The roots of a plant may be described as being its foundation, because they are the organs soonest developed, also the first substantial agents at work towards forming and building up a plant. A plant will not sustain life long without its roots, but there are many instances where the roots will live without branches or leaves for a greater length of time, and they have the power of throwing out fresh ones. However, the more a person dives into the vast subject of vegetable life, the more complicated and marvellous does it appear, especially root action and root growth, the roots penetrating the earth in every direction in search of food, and, when confined within the limits of a pot or other vessel, tightly enveloping the earth in their network as if jealous of the treasures stored up in the soil.

Heat and water are as essential to the formation and growth of roots as they are to wood and leaf development; they must both be present in the atmosphere as well as in the soil, and it is on the artificial application of water to the roots of plants that I purpose offering a few remarks. I have confined them to plants growing under glass, because everything growing under it is influenced by the proper application of water.

It has long since been a recognised fact, that plants search after and obtain food by the agency of their roots, and that the food so obtained is taken up by these in a liquid state and conveyed to the leaves for digestion; and no plainer proof of this fact need be stated than that, when a plant becomes sufficiently dry at the roots to flag, it soon recovers itself when water is applied to them. But without discussing the various other modes by which plants obtain their support, the above facts are convincing that water not only affords food to the plant of itself, but has also the power of rendering the chemical parts of a soil soluble and capable of being taken up by the roots as required. It is, therefore, very necessary for all those who have charge of plants to use every means in their power towards gaining a thorough knowledge of their wants in the way of water at the roots, for it is as easy to give a plant too much water as to give not enough, and either extreme is injurious to the plant and disappointing to the cultivator. Let me impress upon beginners, for whom these remarks are principally intended, that such knowledge is not to be gained without considerable experience and close observation. It will, however, not be very difficult to put my remarks into practice, for I am not prepared to lay before you the results of a series of puzzling and scientific experiments with water, but simply to lay down a few rules and impart some information on watering.

In order that water may be applied to plants under glass in the most beneficial way, it is absolutely necessary to know what relation the temperature of the soil bears to that of the atmosphere of the house. I have tried it many times and have found that from a 16-sized (9-inch) pot downwards the temperature of the soil is about the same as that of the air, and subject to the same variations, but above that size, including the largest tubs and other vessels used for plants, the average temperature in a day is a degree or two lower, but subject to less variation. In large beds and borders from 2 to 4 feet in depth, and with the surface exposed to the atmosphere of the house, the temperature on an average is several degrees lower, with but trifling variation. From these facts it appears that the larger the bulk of soil the more uniform is the temperature. Such facts go far to prove why plants thrive so well when planted out in borders.

In coming to the next subject—viz., the influence of water on the temperature of the soil, I may remark, that during my four years' experience of it, I have tried all sorts of soils in which house plants are usually grown, and I find that water has the effect of lowering as well as of increasing the temperature of the soil; for instance, water at a temperature of 60° applied to a pot of soil having a temperature of 75°, reduces the heat to 67°; but reverse the experiment, and apply water at 75° to soil at 60°, and the temperature rises to 65°, or about one-third of the difference between the two original temperatures. According to another experiment—applying water of the same temperature as that of the soil, the heat of the latter is increased two or three degrees; but if the water is 2° colder than the soil, it has no apparent effect on the temperature. From these experiments we may conclude that the nearer the temperature of the water is to that of the soil, all other conditions being favourable, the more progress the plant makes; for although the variations of temperature caused by water are but of temporary duration when it is applied either too cold or too warm, yet repeated applications of water in one or other of these conditions often cause a permanent derangement of the functions of the plant, which no after-treatment can thoroughly remedy. Three years ago I selected a batch of two dozen even-sized Cinerarias, and placed them under one structure; one half were watered with cold water at a chance temperature, whilst the remainder always had water of the same temperature as that of the house: in three weeks anyone might easily have picked out the former; their foliage was of a lighter green, thinner in texture, and not so large as that of the others; their roots were more wiry, and less numerous; and the plants were many days later in coming into bloom. I have been in the habit of growing Vines in pots from the eye to the ripening of the fruit in twelve months, and when the above experiments were tried with them, the results were similar, with in addition much shanking in the bunches of those Vines which had cold water applied to them. The Vines which I exhibited at the International Horticultural Exhibition in 1866, were from a number of the best-treated ones.

The foregoing facts with regard to the application of water to plants, will be sufficient to teach the gardener the importance of comparing the temperature of the water he uses with that of the house he enters

before applying it to plants, and then, if proper judgment be exercised, the results cannot fail to be satisfactory.

Before concluding, I feel anxious to call attention to a few irregularities in the system of watering practised in many places, the principal being periodical watering and not choosing the proper time for it. The former is bad in principle, because it induces the operator to anticipate the dryness of many of his plants, while others will have become so dry as to baffle all efforts to soak the ball of soil by means of the watering-pot; as a natural consequence many plants are overwatered, while the dryness of others renders it necessary to immerse the whole ball in water. This I consider as great an evil as the former, because the roots are inactive from drought, and an excess of water suddenly sets them to work, forming a number of irregular and deformed growths, and in some cases decomposition and death follow. As regards the proper time for watering, I am of opinion that the best is before the house is opened in the morning, or at shutting up in the after part of the day, because, as the house is closed to external air, evaporation is not going on so rapidly, consequently the action of the roots is steady and progressive, and at all times equal to the demand made upon them by the branches. Excessive dryness and excessive moisture at the roots are the great enemies to plant cultivation.—T. Record, *Gardener to Col. E. Lloyd, Lillesden, Hawkhurst.*

SOUNDS OF TREES.

The sounds and motions of trees constitute subtle but important elements of pleasure. It is not enough that a tree shall have a comely form as a whole; that it cast a dense shade in the sultry days of summer, and that, perhaps, it yield a nut or fruit; and finally that, when it falls before the inevitable axe, its prostrate trunk shall furnish good timber. Besides these uses of bodily comfort and of economy, a tree, like a rich-hearted person, has a hundred harmless ways, which we hardly stop to analyse; but which, if they were suddenly taken away, we should miss.

The murmuring of trees is profoundly affecting to a sensitive spirit. In some moods of imagination one cannot help feeling that trees have a low song, or a conversation of leaves. They whisper, or speak, or cry out, and even roar. No one knows this last quality so well as those who have been in old Oak forests in a storm, with violent winds. A dense forest opposes such a resistance to the free passage of the air, that the sound is much deadened. But in a park, or Oak opening, where spaces are left for the motion of the air, and among open-branched trees, a storm moves with such power and majesty that not even the battles of thunder clouds are more sublime, and under certain circumstances it becomes terrific. At the beginning of the tempest the trees sway and toss as if seeking to escape; as the violence increases, the branches bounce back; the leaves, turning their white under sides to the light, fairly scream. The huge boughs creak and strain like a ship in a storm. Now and then some branches which have grown across each other are drawn back and forth, as if demons were scraping infernal base-viols. Occasionally a branch breaks with a wild crash, or some infirm tree, caught unawares in a huge puff of the storm, goes down with crashing as it falls, and with a thunder-stroke when it reaches the ground. I would go further to hear a storm concert than any music that man ever made. No one who is familiar with forest sounds but is sure, when he hears Beethoven's music, that much of it was inspired by the sounds of winds among trees.

There are milder joys, however, in tree converse. Only this morning I awakened to hear it rain. That steady plash of drops which a north-east wind brings on, is not easily mistaken. I flatter myself that my ear is too well trained to all the ordinary sounds of nature to be easily deceived! I rise and throw back the blinds, when lo! not a drop is falling! It is the wind in my Maple trees. I had thought of that, and listened with the most discriminating attention, and was sure that it was rain.

Twice in our lives we lived in houses built on the edge of the original forests. These had been thinned out and recesses opened up. It happened in both cases that an Ash and Hickory had been left, which shot up, without side branches, to a great height. The trunks were supple and tough. Whenever the winds moved gently, these long and lithe trees moved with singular grace and beauty. As there was no perceptible wind along the ground, their movement seemed voluntary. And yet there was in it that kind of irresolution that one sees in sleep-walking. But as soon as the breath became a breeze, the wide circles through which these rooted gymnasts moved were wonderful. They seemed going forth in every direction, and yet surely and quickly springing back to position again. And in every motion, such was their elasticity, they manifested the utmost grace. The sighing of winds in a Pine forest has no parallel sound except upon the seashore. Of all the sounds of leaves it is the sweetest and saddest, to certain moods of summer leisure.

The Pine sings, like the poet, with no everyday voice, but in a tone apart from all common sounds. It has the power to change the associations, and to quicken the poetic sensibility, as no other singing tree can do. Every one should have this old harper, like a seer or a priest among trees, about his dwelling. Under an old Pine would naturally be found the young maiden, whose new lover was far across the sea. In the sounds that would descend she could not fail to hear the voices of the sea—the roar of winds, the splash of waves running in upon the shore. A young mother, whose first-born had returned to God who gave it, would at twilight go to the Pines; for, to her ear, the whole air must needs seem full of spirit voices. They would sing to her thoughts in just such sad strains as would soothe sorrow. Nor would it be strange if in the rise and fall of these sylvan syllables, she should imagine that she heard her babe again, calling to her from the air.

Every country place should have that very coquette among trees, the Aspen. It seems never to sleep. Its twinkling fingers are playing in the air at some arch fantasy almost without pause. If you sit at a window with a book, it will wink and blink, and beckon, and coax, till you cannot help speaking to it! That must be a still day that does not see the Aspen quiver. A single leaf sometimes will begin to wag, and not another on the whole tree will move! Sometimes a hidden breath will catch at a lower branch, then shifting, will leave them still, while it shakes a topmost twig. Though the air may move so gently that your cheek does not feel it, this sensitive tree will seem all of a shudder, and turn its leaves upward with shuddering chill! It is the daintiest fairy of all the trees. One should have an Aspen on every side of his house, that no window should be without a chance to look upon its nods and becks, and to rejoice in its innocent witchcraft. I have seen such fair sprites, too, in human form. But one does not get off so easily if he takes too much sport with them. The Aspen leaf makes no wounds. Its frolics spin no silken threads which one cannot follow and will not break.

The musical qualities of trees have not enough been considered in planting around our dwellings. The great-leaved Magnolias have no sound. Willows have but little. Cedars, Yew trees, and Lombardy Poplars are almost silent. It is said that the Lombardy Poplar is the male tree, the female never

being brought over. It is very likely. It is stiff enough to be an old bachelor. It spreads out no side branches. Its top dies early. It casts a penurious shadow.—HENRY WARD BEECHER.

ROOTING TENDRILS AND LEAVES.

I QUITE agree with De Candolle in assigning the leaves of plants to be "but a modified, or changed form of branch;" and likewise am quite willing to agree with M. Lestiboudois that the tendrils of the Grape Vine (I have not experimented with the tendrils of any other class of plants), are nothing more than homogeneous branches, not leaves.

The reason I claim such to be the case is this:—I have repeatedly taken the leaf of the Grape Vine, and after detaching its petiole from the stem have rooted it (the leaves) with the same degree of certainty as the cuttings of the branches are rooted; although I must confess that they are longer in rooting, and much longer in throwing up a bud from the collar of the leaf than the ordinary cuttings are; but they will eventually throw up a bud, and ultimately make as good a plant as the plant grown from a single bud. After being so successful with the leaves, I thought that I would take the tendrils in hand, and try and see what I could make out of these. I accordingly, the past season, put in several pots of tendrils of the Rogers No. 4 variety, and after a long time was highly gratified to find that the majority of them had emitted roots, and after being potted-off singly, several of them actually made leaves, and filled the pots with fleshy, healthy roots, but did not show any buds before the cold weather set in and stopped their growing. I am sorry to state, however, that I have lost these plants that I had intended to have grown on next season. It will be noticed that I have called these rooted tendrils, plants; I call cuttings of anything young plants, as soon as they have made roots. My man, not being cognisant of these plants, threw them away with the refuse.—JAMES CHARLTON, *Rochester, New York.*

[To this communication, published in the "American Gardener's Monthly," Mr. E. Fryer, of Naperville, adds the following remarks in a subsequent number of the same periodical.]

Almost every observing gardener accustomed to the growing of Grape Vines, foreign and native, will have noticed on strong-growing, healthy Vines, that a tendril will sometimes change its form and become a miniature branch, small leaves showing on the upper part of the extended tendril. This fact, I think, goes to show that such tendrils at least are rather more than "modified leaves."

I have in many instances taken the leafy part of this tendril, when it acquired the proper condition, cut it up in pieces with a leaf at each, and rooted them in the ordinary way; the second season they will make strong plants, but as to whether they would bear fruit as well as cuttings struck from bearing wood, I have not yet had any experience. Healthy leaves I have struck with certainty and ease, and in one season they become a plant perfect in all its parts. With the tendril only, I confess I have not been so successful as Mr. Charlton. I have rooted them occasionally, but never succeeded in obtaining a perfect plant having either leaf or branch. If Mr. Charlton means by tendril what is generally understood as such, having no leafy appendages whatever, and has obtained from these leafy plants that ripened, he has accomplished a feat which, though it may not be of value to the public, is certainly new and interesting to the general propagator. The tendrils of the Cobæa scandens and many other strong-growing climbers will root as well as those of the Grape Vine, but require considerable time—from thirty to one hundred days, for the rooting process. In every instance I have failed to obtain a perfect plant from any of them that I have experimented with. Not so with the leaves; the Rose, Dahlia, Cobæa, Lophospermum, Passiflora, &c., will all strike at the base of the leaf and become perfect plants in one season. The leaf of the Hoya, if taken from a healthy plant, will generally make a plant with a growing shoot the first season; but sometimes if taken from a plant that is not vigorous, or from near the base, owing probably to a want of due development in the leaf itself, though it will root, it may remain in a semi-dormant condition for years without sending up a shoot. Almost everyone is acquainted with the method of propagating the Begonias, Gloxinias, &c., from leaves, which, by being gently pressed on warm sand or earth, make roots, and soon send up leaves, making many, yet perfect plants from a single leaf. These facts, though only some, perhaps none, of them are new, yet simple as they are, in the hands of a practical man go far to prove the correctness of the theory of the man of science, De Candolle, that "the leaves of plants are only a changed form of branches."

The practice of striking green cuttings of all the more common bedding plants, and also of hardwooded plants, such as the Camellia, Tea plants, &c., when these latter are struck from green cuttings, with only a leaf and small piece of stem to each cutting, is also in support of De Candolle's theory. Take away the leaf and the cutting will not strike; in most cases if the leaf is destroyed after the roots are formed the plant will die. In the hands of experienced propagators there is a wonderful power in a healthy leaf. The creed of the old-school gardeners, "an eye for a root, and an eye for a shoot," is wholly ignored by our American practice of the present time. We pay no attention whatever to an eye or bud at the base of the cutting, unless the cuttings are so short as to require it, but it is not at all necessary to its rooting. As an instance, with Verbenas, which are now required in such multitudes, we cut off all the soft part of the young shoots, and these are cut up in pieces with only a pair of leaves on the top, no bud at the bottom of the cuttings, unless required as above stated. Most other bedding plants the same.

The Camellia which, by the old English practice of striking ripened cuttings of the single red variety for stocks, required from eight to twelve months for rooting, is now accomplished in from six to eight weeks when green cuttings are used. With us the rooting of the Camellia is not confined to the single variety, but is applied to nearly all varieties, the old but beautiful Alba plena being one of the freest-rooting of all. While on the subject, I will here state what may seem strange to some, that here in the West the Alba plena on its own roots is longer-lived and more healthy than when worked on the single stock. So of that celebrated variety, Sarah Frost; it grows as strongly, if not more so, on its own roots than when inarched or grafted.

TREE-PRUNER.

Fig. 2, shows how the scissors are operated by a handle, which gives great power by the leverage, and very large limbs can be cut off with ease. *Fig.* 1, shows the saw arrangement,

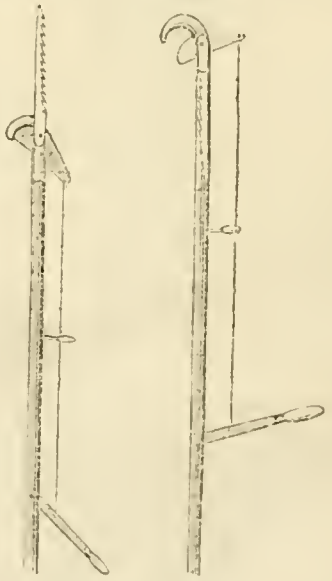

Fig. 1. Fig. 2.

which is closed in *fig.* 2, opened out and ready for use. We have had opportunities of examining many kinds of tree-pruners lately, and find this the best of all. — (*American Gardener's Monthly.*)

WILL THE WELLINGTONIA GIGANTEA THRIVE HEREAFTER?

To disparage Black Hamburgh Grapes, Green Gage Plums, Jargonelle Pears, and some other kinds of fruit, has much the appearance of horticultural treason; and if this be the case

with fruit, what will be said when that king of the forest, the Wellingtonia, is assailed? Yet it has been hinted that in this country the tree is not likely to hold the high position which at first it seemed destined to occupy.

A few years after its introduction much emulation existed amongst those who had the best specimens, and for a year or two the heights of the most promising plants were recorded in the gardening periodicals; but this practice has died out of late, so that I fear the tree is not such a favourite as it was. Be this as it may, some inquiry into the present condition of those trees which occupied so high a position about 1860 or 1862, cannot fail to elicit something; and if the result should show that one-half of these trees have succumbed to disease or climatic action, we may then conclude that the tree is not destined to effect the change in our arboricultural scenery which was expected. I myself have grave doubts of the plant's doing well for any length of time. Occupying in its native country a higher elevation by many thousands of feet than can be assigned to it here, it is quite possible the rarefied air of these upper regions may suit the plant better than the dense atmosphere of its usual sites with us. Before, however, venturing further conjectures on this question, let us inquire if there be reason to suspect it of constitutional debility, or, in other words, if many of the specimens of large size show signs of ill health or want of vigour; and should one-half of them do so, it is sufficient to create alarm if no local cause can be assigned. The vigour with which the tree grew at first, and its reputed hardiness, led many to predict for it a great future (myself amongst the number, although I never supposed that it or any other imported tree would exceed our indigenous trees in size), and I yet hope this tree will in many cases equal native ones; still we have before us the unpleasant sight of trees 25 feet high and upwards falling into an unhealthy state. If this should be the case generally, then adieu to the Wellingtonia as an ornamental tree; and as I have heard of some trees, not so high as 25 feet, having "gone off" in an unsatisfactory manner, it becomes important to publicly ask the question, "Are such cases frequent?" I hope the answer will be in the negative; but a fair public inquiry will solve the problem.

Some years ago a fine tree of this species occupied a place along with other Conifers and ornamental shrubs in the nursery ground of Messrs. Bunyard, of Maidstone. The soil was dry and fertile, overlying the limestone rock, called here Kentish rag. This tree grew vigorously for some years, until I believe it attained something over 13 feet in height, when it gradually declined. The reason assigned by some was, that its roots had been impeded in their descent by the rock. This was not a likely cause, and might not have been much noticed had not some Wellingtonias at other places fallen into a similar condition; and I recollect a well-informed nurseryman from Scotland pronouncing it a "rank impostor." This, I think, was more than was deserved, but enough was said against it to call for further inquiries, and, by way of setting an example, I may say that one of the largest plants we have here, which in the autumn of 1865 was upwards of 18 feet high, and as healthy as could be until the dry weather of last year, began to show signs of distress in the July of that year, its inner foliage dying off, and also a branch or two near the bottom. As the tree occupied a position on the lawn where its roots were not likely to encounter those of other trees, I expected that a good watering at the time, and the ample rainfall of the past winter and spring, would have restored the tree to its wonted vigour. I find, however, this is not the case, the ripening and dying off of the foliage going on more extensively this summer than last, and some branches have actually died. The leader continues healthy, and the tree has grown taller, being now upwards of 26 feet high, and, like most of its class, symmetrical in outline; but I fear it has arrived at that period when growth is slow, if not uncertain and sickly, and bearing of other trees of a similar size going wrong, I begin to fear for this. All our other trees seem healthy enough, the next largest being nearly 23 feet high, and in every respect a more robust tree than that described, and it stands in the open park with nothing higher than itself for 100 yards or more. A fence serves to protect it from cattle. The spread of the branches is nearly as many feet in diameter as the tree is high, and it is succeeding well; so, too, are all our other trees, of which we have a great number; but if the defective constitution of the plant only exhibits itself when it has attained some size, there may be time enough yet for them to go wrong. The situation of the tree which has shown signs of not thriving is a favourable one, much more so than that of a fine Thuja Lobbii not far from it, which has outstripped it in growth, being now nearly 29 feet high, and as straight as a gun barrel. This fine tree has grown nearly 10 feet within the last four years, and in the preceding five years it grew upwards of 15 feet. I am rather sorry to say it is now loaded with fruit, and that may, perhaps, check its future growth, otherwise it is a species not planted to half the extent it ought to be. Are there any specimens of this tree higher than that referred to—29 feet? Probably there are, as the situation in which it is placed is not one of the best.

Returning to the subject of Wellingtonia, I may add that a fine tree in the garden of Messrs. Hollingworth, at Maidstone, continues in the most robust health, and is now 28 feet high; and I believe a still finer one at Fairlawn, the seat of J. Ridgway, Esq., is also healthy and vigorous, being 31 feet high. These examples ought to create a hope that in the cases where a retrogression has taken place, some local cause might have affected the specimens, and let us trust it is so; but I am told of more failures than I have authority to name, and consequently feel somewhat afraid this promising tree is not so certain of future success as its friends would like. As it has been much planted of late years, and oft-times as a memorial tree, it would be well to inquire whether the condition of the largest specimens, or of those which ought to be the largest, is such as to warrant its being so generally adopted by those who plant for the next century or the one after that, as well as by those who do so simply for immediate effect. I am far from despairing of it yet, but I have heard more to its disadvantage lately than is at all agreeable.—J. Robson.

NOTES AND GLEANINGS.

We have received from Mr. Wray, of Ramsgate, a bunch of Muscat Hamburgh Grape, from a Vine grafted on the Syrian. The berries are the largest we have ever seen of that variety, and this increase in size is evidently due to the stock. The bunch is well set and large. The Muscat flavour is not well marked, though traceable, indicating that the stock also influences the flavour; but as the berries were not quite ripe, it is probable that this may yet be developed.

—— The Knight of Kerry informs us that his gardener has grown a Beechwood Melon of 12 lbs. weight, and asks if that "exceeds the usual scale." It does so most assuredly, as we never heard of one weighing anything like so much. We should be glad to be informed of any unusual weights, such as this.

WORK FOR THE WEEK.

KITCHEN GARDEN.

Destroy weeds, for if they are now permitted to seed, great labour will be required to keep them down in the autumn. Transplant the last spring *Broccoli*, and the Grange's, Snow's, and Walcheren, sown in July for lifting to be packed in beds for the winter. *Brussels Sprouts*, *Savoys*, and Curled *Kale* may still be planted, and every spare piece of ground filled with them. *Cauliflower* and Walcheren *Broccoli* may now be sown for the spring crop. A few more *Dwarf Kidney Beans* may be tried for the last supply. *Peas*, the Marrow kinds should be topped as soon as they reach the height of their stakes. Sow *Chervil*, *American Cress*, and *Parsley* in a sheltered situation. Sow Early Horn *Carrot*, to remain in the ground for winter use. Cut herbs, if not already done, and keep the hoe moving amongst all growing crops. High cultivation amongst all green crops will amply repay any extra labour it may require. Hoeing or forking amongst growing crops, provided the roots are not injured, is highly beneficial, and will prove a sort of fallow for successive crops.

FRUIT GARDEN.

Apples and Pears should be gathered as they ripen. Early fruit, more particularly, is the better of being gathered a few days before it ripens on the trees, as in the latter case it usually turns mealy directly. Protect the finer kinds of fruit from wasps. Peaches and Nectarines should likewise be gathered a day or so before they are quite ripe.

FLOWER GARDEN.

The beauty of bedding plants is in most localities but of comparatively short duration, even in the best of seasons, and

now they are in full flower every care should be taken to render them as attractive as possible. Go over the beds frequently, and remedy any defects that may be perceptible; pegging down plants which have an inclination to grow above the others, and keeping the edges of the masses well filled up, but not allowing them to become too bulky. Where the plants are pushing freely, some considerable trouble will be involved in stopping the shoots; but this operation must be repeated with sufficient frequency to keep the plants within due limits, since nothing looks worse than their running over the edging and encroaching upon the grass. Attend to plants in vases, taking care that they do not suffer from want of water at the roots, and they may even be benefited by an occasional supply of manure water, provided it is given often and weak; too strong doses do more harm than good. All evergreens in unsuitable situations may now be moved. Where a general transplantation of evergreens is intended, the middle of next month is a suitable time for the operation. Deciduous trees and shrubs, as a matter of course, should not be transplanted until they have shed their leaves. The roots, however, may now or very soon be cut round preparatory to removal. This is a good time for removing the dead wood from shrubs, and controlling their luxuriant growth by careful pruning. Preparation must be forthwith made for next year's floral display. If a good stock of Scarlet Pelargonium cuttings has not already been put in, let it be done immediately. Proceed afterwards with the general bedding stock. Endeavour annually to get some new plants, and to vary your arrangements, that the scene may not be monotonous. With the exception of propagation, all else is mere routine for the present.

GREENHOUSE AND CONSERVATORY.

In keeping up a stock of plants there must be, besides those depended on for the principal show of bloom, younger plants coming on to supersede those which in consequence of old age or decay have to be consigned to the rubbish heap. I previously adverted to the rapidity with which even difficult plants may be grown. Any plants, therefore, in pots which it is desirable should be grown quickly, and to which has been allowed a slight rest after their spring growth, may now be shifted according to their habits and condition. It will not, however, be advisable to give them so large a shift at this season as might have been ventured upon in spring, as whatever wood is made after the present shift must be ripened, unless in the case of such free-flowering plants as bloom on the current year's growing wood. As this shift will have to carry the plant through the winter months, the drainage of the pots should be ample. After a few days an open situation should be selected for the newly potted plants, that the new growth may be made under conditions favourable for its maturation. The greatest care must be taken where valuable tender-rooted plants are out of doors lest heavy rains should damage their roots, and no time should be lost in placing such under the cover of glass. The hardier plants left out should be examined frequently, to see that the water passes freely through the pots. Hyacinths and other Dutch bulbs are now arriving. Those for early forcing should be procured and potted, and even where that is not intended there will be a better chance of obtaining good bulbs early than late, when all the best are bought up. Van Thol Tulips for forcing may be potted early next month; place them on coal ashes, and cover them as previously recommended for Hyacinths, removing them early in November into heat; the bulk need not be potted until late in October, and a last batch of Tournesol or Rex Rubrorum towards the end of November. Orange trees in pots, to be forced for winter decoration, should now be fully exposed in order to well ripen their wood. The Mandarin, being a free grower with a dwarf bushy habit, small foliage, and a most abundant bloomer, is probably the best for this purpose; but any of the varieties flower profusely provided the wood is thoroughly ripened in autumn. These and Daphnes, should be grown largely where sweet-scented flowers are in demand for winter. Take care also to have plenty of Salvia splendens, which is an exceedingly gay plant, and very useful for mixing among Chrysanthemums in the show house.

STOVE.

A number of Orchids will by this time have made their growth, and may be removed gradually to a drier and cooler atmosphere. Those which continue growing must be syringed two or three times a-day, and a humid atmosphere kept up by watering every vacant part of the interior; at the same time plants on blocks or suspended in baskets should be frequently soaked, so as to thoroughly moisten the growing material.—W. Keane.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Forked over the ground among Cabbages, Coleworts, and more especially the Cauliflower plants recently turned-out. Watering after planting is a great help until the plants are established; yet when rapid and healthy growth among vegetables is desirable, we do not attach sufficient importance to surface-stirring the soil either by hoe or fork—the latter being the better in all cases where weeds are not troublesome. To Mr. James Barnes, of Bicton, the country is especially indebted for drawing attention to this work, which was too often sadly neglected. We turned-out a piece of Cauliflower after Peas, Beans, &c., with balls, watering at planting, and on an average each plant showed only one decaying leaf; we gave the plants a little soot water, and that caused them to hold their own, and grow in the warmest days, though we did not think they were growing fast enough. A few showers had rather crusted the surface of the well-pulverised soil, and the day after the watering the soil between the plants was forked over 2 or 3 inches deep, and the mere access to air thus given has acted like a charm. For several days you might almost have thought you saw the plants growing. We mention this fact in no spirit of egotism, but merely for impressing on the holders of small gardens the importance of surface-stirring among all growing crops, not only for keeping them clear of weeds, but of greatly adding to rapidity and luxuriance of growth. Some time ago we mentioned the importance of mulching with short grass, chiefly for keeping excessive heat out and moisture in; but when the mulching is left on for a long time and is at all thick, it excludes the air too much, and therefore requires to be broken and turned frequently, when the full benefit is obtained. We have often been forced to mulch Peas in a dry hot season, but if such mulching caked on the surface like a drugget, the Peas never succeeded so well as when it was frequently broken, so that the air could have free entrance whilst the force of the sun's rays was excluded.

With water at command, and the surface of the soil loose, and frequently stirred, we would not trouble much with mulching. It is a great help when the other means are limited; but, like many a good thing, it is often misused—for instance, when applied so early as to keep out the genial heat of spring and early summer, or allowed to be so close in summer as to keep out free atmospheric influence. Many a time have we seen watering resorted to, when a surface-stirring would have been far more effective. The work, too, is much lighter than watering.

Took up our earliest Horn Carrots, as they were full-grown and clean, for if left longer in the ground they would be apt to throw out roots from the sides, and perhaps worms would disfigure them. One reason, besides, for lifting them was, that we were much in want of a good piece of ground for sowing winter Onions. Our spring-sown main crops of Onions are still growing so fast that we are averse to disturbing them as yet. We have no doubt that Carrots often remain too long in the ground, and thus those otherwise sound are often disfigured. Hoed the last-sown crop, which is still small. This will keep us in small Carrots until we have a supply of the forced Horns and the small Dutch in spring. Sowed our third piece of winter Spinach, and if the weather be fine we shall sow a few rows in September. Run the hoe between the rows of the first sown. We generally sow these crops rather thinly, as that saves the trouble of thinning. When the seeds are sown thinly, however, it is advisable to red-lead them, as there is no seed to which mice are more partial. In a seed-room they will make chaff of Spinach seed before they touch Peas or Beans.

Peas.—There is in gardening always something to puzzle even a strict observer. We sowed some rows of Dickson's Favourite Pea to come in late. Of these some look most promising, as green and flourishing as possible, and others are already becoming mildewed at the bottom and looking badly. As far as we know, the ground for all was much alike, the treatment afterwards much the same, and yet the results are so different. There are many simple things that bid defiance to our knowledge to account for them. Why, under similar circumstances, should one row of the same kind of Pea be so healthy and another spotted with mildew? A little sulphur and lime dusted on the mildew will do good, especially if rain,

or the garden engine, follow a couple of days afterwards. Mildew will make its appearance in autumn, when there is a moist atmosphere and a rather dry soil, and when the reverse is the case, when there is a moist soil at the roots and a cloudy cold air around the tops. The roots dry, with a free evaporation from the foliage, and moisture at the roots with a partial stoppage of perspiration from cloudy showery weather, are very likely to produce mildew.

Celery.—Finished earthing-up to its full height the dwarf Celery we intend for use early in September. Our next bed of the Incomparable White is tolerably strong, but shorter than usual. One advantage of this kind is that if you grow it from 15 to 18 inches high, you can send it to table 12 or 15 inches in length. We have had fine specimens for the salad-bowl from plants not more than 16 inches in height—a matter of importance for the holders of small gardens. We generally grow ours in beds, three or four rows across. Such dwarf kinds, it will be observed, need but little earthing-up, and as we tie every plant with a slight strand of matting, there is no difficulty whatever in the earthing-up, with or without boards placed across between the rows. The bed referred to, we have had thoroughly cleaned at the bottom, removing all suckers with the point of a knife, but without injuring the leaves or leafstalks of the main plant. All the dwarf whites we have tried are more apt to stole at the bottom in this way than the taller-growing whites, or even the general run of reds, though all do it at times more or less. These plants being of a good size when planted out, were looked over then, but still a few more suckers will be likely to show themselves, and if left untouched, especially when the planting is rather close, will so far detract from the strength of the main plant or head. Sometimes in early Celery we have left the suckers, and then on taking up for salads the smaller blanched suckers proved useful for soups and stews. We have thus had a good stick for table in the centre, and from four to half a dozen small blanched sticks or shoots round it. In general, however, the best Celery is obtained by nipping out all the suckers that appear, so that the strength of the roots shall be thrown into the one main plant or stem. After planting, it is of little use removing the suckers until the plants attain a good size.

Having thus dressed the bed, we proceeded to tie the plants 8 or 10 inches from the ground-level. In tall sorts, as in a red bed, the strands of matting are placed higher according to the height of the plant. This tying encourages the central leaves of the plant to rise, and even causes blanching to commence at the centre. There is no nicety required in this tying, except to be careful to tie loosely enough, so as to leave plenty of room for the plant to expand in growth. Even men accustomed to the work are apt to tie the plant too tightly. All that is wanted is to keep it together, but to give plenty of room for expansion. The object of the tying, besides what is stated above, is to keep the heart free, and secure from earth finding its way there, as it often causes the centre to rot. The disadvantages of tight-tying are that the band is apt to cut the outside footstalks of leaves, and the heart instead of rising freely is forced to turn back on itself or protrude itself at the sides.

The removal of the suckers, and tying, involved trampling the surface of the bed; therefore, when tying was finished, the points of a light fork were used on the surface; and as the growth was not too strong, as well as to drive away worms, &c., a little soot was strewn along the bed, and a good watering was given. In a week or so the most careless tyers will see the importance of loose tying, as generally with such encouragement the growth is very rapid, after removing the suckers. This bed will be earthed-up at one operation, or at most in two—generally at once—in pieces as we expect it to be wanted, say three weeks beforehand When long tied, less time will do. For instance, in this large bed, most likely eight days or so after giving a good watering, we shall earth-up at once 4 or 5 yards of it, following with a piece more every eight or ten days, until the bed be finished, and so on with the succession beds. By doing this a bolted or run head of early Celery is with us a rarity. We cannot say what may be the case this season, for our young Celery had scarcely justice as respects moisture; but for a number of years we had a single bolted head of early Celery when we used to have it much earlier than now—that is, fit for use in the beginning of July. Of course when to be used so early it had to receive a considerable amount of artificial heat; in fact, the trench that ultimately received it was a mild hotbed at bottom.

We must excuse ourselves for entering into the above details, by stating that numerous subscribers wish to know all about our mode of earthing-up, as so different from that of all other writers, except those who have evidently copied from us, and who uniformly recommend, in earthing-up Celery, to give only a few inches at a time. Now, as frequently stated, we have no objection to this plan late in autumn, when the sun's force is declining; but we have no hesitation in stating that bit-by-bit earthing-up in July and August, and even the first part of a sunny September, is the chief cause why, when early Celery is taken up, there are so many bolted heads, of no use for the salad bowl, or as an accompaniment to cheese. Our practice rests on the simple fact, that the Celery is a ditch-side plant; that to keep it growing freely it must have moisture to meet the free evaporation from its foliage on a sunny day; that to make it throw up its flower-stem freely, the best mode to adopt is to keep it dry at the roots, and this is what is constantly done by the bit-by-bit earthing-up system, as, supposing you give a good watering at first when you add 2 inches of soil, and 3 or more inches over it at earthing-up, no rain will reach the roots, and the evaporation from the foliage still goes on; so that in lifting the Celery it will not be uncommon to find the bulk of the roots surrounded by soil which is dust-dry. Can we wonder that the plants in self-defence throw up their flower-stems?

Before leaving the subject we would advert to a few correlative matters. Our tying-up acts as slight earthing-up would do, but it leaves the roots open to natural or artificial moisture. Again, we have grown early Celery to an immense size; but except for a particular purpose, we now look on all such huge heads as labour misapplied, or even worse; first, because from these huge plants, like a man's leg, the head that was obtained for table was not at all proportionate in size to that obtained from our compact moderate-sized plants in a bed; and secondly, because these huge plants, if not protected from wet, were a great loss and disappointment, as in rainy weather the wet found its way down to the heart of the plant, and unable to find its way out, it remained there as in a cup, became foul like other stagnant water, and finally scarred or caused the valuable part of the Celery to decay. We have taken up in September the large heads referred to, and found fully one-half only fit for the rubbish heap. For economy in every way, middle-sized heads are best, and they will be sweetest when the manure used is sweet and well decomposed. In earthing-up Celery for early use, as on our plan it will never stand long nothing is better than the common soil. For late Celery, and that which is to remain through the winter, and especially in heavy soils, the Celery will keep better if surrounded with ashes, sand, moss, or anything that will keep slugs and worms away, and allow superfluous moisture to pass off. An inch of coal or furnace ashes round the plants will be of great advantage in keeping them sound.

Insects and Popular Prejudice.—We shall refer to previous weeks for other departments, and say a word on the prevalence of insects, and the wonderful quantity this season of the Coccinella, called familiarly the lady bird, lady cow, &c., too generally known from its prettily spotted outside covering to need particular description. We lately stated that though free from the infliction in the garden, the neighbouring fields and gardens had suffered severely as respects Peas and Beans from different kinds of fly. Some have brought and sent to us lots of the pretty lady bird, which they said quite covered their Beans and were ruining them, and that the more they killed the more numerous they seemed to be. The innocent, pretty, lady bird was blamed for the very evil which it was doing its best to mitigate or remove. Our continental neighbours are more intelligent, for they encourage these pretty insects to harbour in their gardens. We are not so sure that the lady birds in their perfect state devour in great quantity the different kind of aphides that infest our vegetables and trees, though when we have shut up such insects along with leaves of Plums and Beans, we found the leaves clean, and the insects with which they were encrusted out of sight, not one remaining. In the larva state, the lady bird devours aphides of all kinds greedily, and the chief work it performs now on all vegetation encrusted with fly, is to deposit eggs where the larvæ will be likely to find plenty of food. Never in our experience did we know the lady birds appear so early and so plentifully as this season. On banks and warm pastures, we saw them plentifully in March and April. Now in garden, field, and pasture, they seem crowding everywhere, and so thickly do they swarm in some places of public resort, that ladies cannot walk, we are told, without

crushing them. We have seen great numbers of them, little clouds in fact, on the wing, and that is not very common. Sportsmen say that it will be a rare time for pheasants, which are fond of them. They are friends to the gardener, and if some entomologist would enlighten us as to the time they generally take to pass through their various transformations, it would be very interesting and profitable, and help to do away with much ignorance and misconception. We have several times instituted experiments to satisfy ourselves, but chiefly from accidents our experiments were not fairly carried out so as to be trustworthy.—R. F.

COVENT GARDEN MARKET.—August 25.

Our market is well supplied, and business has been somewhat better, but no advance in prices can be maintained. Pine Apples, Grapes, Peaches, and Nectarines are sufficient for the trade. The Potato trade is heavy; there are large stocks on hand, generally free from disease.

TRADE CATALOGUES RECEIVED.

William Paul, Waltham Cross, London, N.—*Bulb Catalogue*, 1869.

James Veitch & Sons, Royal Exotic Nursery, King's Road, Chelsea, S.W.—*Catalogue of Hyacinths and other Bulbous Roots.*

B. S. Williams, Victoria and Paradise Nurseries.—*General Bulb Catalogue, and Catalogue of Fruit Trees, Roses, &c.*

John Scott, Merriott Nurseries, Crewkerne, Somerset. — *Catalogue of Flower Roots.*

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely to The Editors of the Journal of Horticulture, &c.*, 171, *Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

Books (*J. Carrington*).—The book you name is "Thomson's Handy Book of the Flower Garden," published by Blackwood & Sons. (*Subscriber*).—There is no such work, but you will find the subject treated on in McIntosh's "Book of the Garden," and Thompson's "Gardener's Assistant." (*G. W.*).—"The Garden Manual," which may be had post free from our office, for 1*s.* 8*d.*

Rendle's Patent Plant Protectors (*Rev. E. H.; E C. S.*).—Mr. Rendle's address is 68, Welbeck Street. The best book for your purpose is the "Cottage Gardeners' Dictionary."

Twin Cucumber (*Cucumber*).—This is not new, though unusual. It is caused by the union of two ovaries.

Cucumber Diseased (*Subscriber, J. E.*).—We can offer you no remedy for the disease. It has baffled all the most experienced cultivators. Do you not think your spring water is too cold, and contains some mineral substance prejudicial to the plant?

Vicomtesse Héricart de Thury Strawberry (*F. H. G.*).—It was advertised in our number for August 5th. We cannot depart from our rule of not recommending one dealer in preference to another. Nurserymen who have a stock of this variety should advertise.

Alpine Strawberries (*C. W.*).—Blanche d'Orleans, white, larger than the common White Alpine; Galande, dark red, of agreeable flavour, an abundant bearer; and Bruno de Gilbert, almost black, very abundant-bearing in autumn. Alpine Strawberry runners can be obtained of most of the principal nurserymen. September is a good time to plant for summer bearing, and March for autumn. We prefer raising plants from seed, sowing in March in a shallow box, placed near the glass in a frame, and hardening the plants well off previous to planting them out. We plant them 1 foot apart on an east border. Plants from seed are of freer growth, and produce abundantly.

Wintering Coleuses (*J. W. C.*).—They require to be kept in rather small pots in a house, where the temperature does not fall below 40°, but is generally 45°. The atmosphere should be dry, and no more water ought to be given than is required to keep them fresh; indeed, the drier they are the safer they will be in winter. If they are in the open ground they should be taken up before frost, placed in small pots, just large enough to hold the roots well, and set in a light and airy position. The soil ought to be sandy and not rich; light loam with a little leaf mould is most suitable. You should write to Mr. Looker for the information you require.

Bougainvillea lateritia (*T. C.*).—When the plant begins to grow it should be encouraged with an abundance of moisture, and have free ventilation. The shoots must be trained near the glass. This treatment ought to begin in March, and should be continued until August, when the atmosphere should be kept dry, and no more water given at the root than is needed to keep the leaves fresh, though if they flag a little under powerful sun no harm will result. The temperature should be proportionate to the dryness, and fully as high as when the plant was making growth. From March to October it should have a stove heat; from October to March a temperature of not less than 45° in severe frost, and generally one ranging from 45° to 50°.

Digitalis lutea (*Idem*).—We are not aware that it is indigenous to this country. It is a native of France. Seed may be had of the principal seedsmen.

Cool-house Orchids (*Idem*).—The Orchids, now that the Grapes are cut, and you wish to throw the house open, need not be removed. They will be all the better of the increased ventilation and dryness. We presume that it is not intended to remove the lights, that the plants will be secure from heavy rains, and that in very moist, cold weather, gentle fire heat will be given to dissipate damp.

Blanching Celery in Sawdust (*Amateur*).—You may blanch Celery in anything that will exclude light. See "Doings of Last Week."

Celery Hollow (*Amateur*).—The chief causes of Celery becoming hollow are poor soil and a deficiency of moisture during dry, hot weather, and not unfrequently sudden checks given in the early stages of growth, in pricking-off, transplanting, &c. Cole's Defiance Dwarf Red is an excellent sort. Dickson's Manchester Champion Red, and Champion White, an early sort of large size, are good for growing in quantity.

Prizes for Bouquets (*Evergreen*).—So soon as you prove that there was any injustice done, we shall not be backward in helping to expose it. Your insinuations need no reply from us.

Propagating Hollyhocks (*T.*).—As there are no shoots from the base, and only the flowering stems, and as the sort is desirable, we would cut the stems off to within a few inches of their base, and make cuttings of them. For each cutting two joints will be sufficient, and the stem must be cut across below a joint. Remove the lowest leaf, and half of the upper one, and insert the cuttings round the sides of pots, well drained, and filled with moist sandy loam. The soil should be firmly pressed round the base of the cuttings, then fill up the holes with sand. If the joints are long, put in the shoots as eyes with but one joint, cutting in a sloping direction about half an inch below the eye, and about an inch above it, and put into the soil so that the eye will be covered about half an inch with fine soil. No water should be given, as the soil ought to be moist before the cuttings are inserted. Plunge the pots to within half an inch of the rim in a hotbed of from 70° to 75°, using sawdust or ashes for plunging them in, keep closely shaded, and admit no air, excepting a little for an hour in the morning, to carry off any accumulation of steam. In six weeks the cuttings will begin to grow, and should have a little water, without, however, wetting the leaves. When rooted, pot off singly in small pots, and place in a cold frame, keeping it close and shaded for ten days or a fortnight; then gradually admit air, and remove the shade by degrees. Water should be given as required, and abundance of air. No time should be lost in putting in cuttings, so as to have them rooted before winter. The old plant should be taken up after flowering, potted, and wintered in a frame. It may produce shoots suitable for cuttings in spring, the tops only being employed.

Leucojum vernum Sowing (*M. D.*).—The seeds should be sown now in light sandy soil, and covered with fine soil about a quarter of an inch deep. The seeds may also be kept through the winter in dry sand in a cool dry place, but are best sown as soon as ripe, giving a light mulching of partially rotten leaves before severe weather.

Picotee Pipings (*A. E. F. C.*).—You should continue the same treatment until the cuttings or pipings begin to grow. This you will know by the fresh leaves in the centre of the cuttings becoming longer than the old leaves. When this takes place the pipings have rooted, or have formed a callosity which will root. More air should be given gradually by day as well as by night, and the shading should be withdrawn by degrees. The plants will be fit to pot off singly in about six weeks from the time of putting in, by which time they should be well hardened-off, exposing them fully at all times, except during heavy rains. Give shade from bright sun for a few days after potting, and afterwards expose them freely to the air, but protect from heavy rains and severe frost. In mild

weather, when it is necessary to keep on the lights in order to throw off heavy rain, these should be raised at back; in frosty weather keep them close, and cover them with mats at night. Avoid having the soil very wet in winter. Give an abundance of air. Plant out in March.

Climber for North-west Aspect (*Summers Ville*).—The fastest-growing climber for a north-western aspect is Virginian Creeper. If you wish for a flowering plant, a Dundee Rambler Rose, or Cratægus pyracantha may suit you. Rægner's Ivy, with very fine heart-shaped leaves, is also a good evergreen for the purpose.

Covering a Wall with Ivy (*Idem*).—The best plan is to procure some good strong plants in pots, which may be had in most nurseries; plant them in rich sandy soil, and keep them well watered in dry weather when the plants are growing. Secure the shoots to the wall, spreading them out so as to cover every part. If you mix seeds with the mortar they will not grow. Ivy is not an epiphyte, but has very extensive roots, and to succeed well requires a rich open soil.

Rose Cuttings (*Q. Q.*).—We would at once plant out in a carefully-prepared bed the Rose cuttings put in last October and March. You will gain a year by planting now. The plants will be well rooted before winter, and prepared for a good growth and bloom next year. Take up carefully, and after planting water, if the weather prove dry.

Roses against a Fence (*Idem*).—The Hybrid Perpetuals would be the better of being unnailed, and allowed to grow at will next year; but we would remove them this autumn, and plant them in a cooler position. The Perpetuals like open, not hot, dry situations. We think the Tea-scented Roses you name would not succeed planted on the north side, and their shoots trained down the southern side of the wall. The wood would not ripen, and the shoots would be damaged, if not destroyed in severe weather, from being unripe. They should be planted on the south side, and are well worthy of such a position, and far more suitable than the Hybrid Perpetuals.

Tricolor Pelargoniums (*Idem*).—The colours of the leaves would be improved if the lights were put on, air admitted freely day and night, the lights being drawn off on fine days, but the plants protected from rain.

Pelargonium not Flowering (*A. G.*).—Your Pelargonium must be of very delicate constitution and languid growth. The only advice we can give you is to stimulate it by enriching the soil.

Seedling Lobelia and Pansy (*Peter*).—The flowers when they reached us were quite withered. The Pansy was very dark, but was too shrivelled for any opinion to be formed as to its merit. If you have any subjects which you wish to submit to the Floral Committee of the Royal Horticultural Society, you may send them, carriage paid, to the Secretary of the Committee, Royal Horticultural Society, South Kensington, and they must arrive there before half-past 10 A.M., on the day on which the Committee meets. It is not necessary to attend personally.

Desfontainia spinosa (*J. W. W.*).—It succeeds in the open ground, and would no doubt thrive if you planted it in a sheltered border; but we would not advise its being planted in the Rhododendron bed, nor yet along with the Camellias, for they require a more sandy soil than Rhododendrons—besides, they flower at different times, and are different in foliage and habit. The Desfontainia is quite hardy, and a fine Holly-like shrub, with bell-shaped red flowers.

Planting Camellias Out of Doors (*Idem*).—They would no doubt thrive in the centre of Ireland, but for reasons above mentioned we would not plant them in the Rhododendron bed, but prepare a bed of light fibrous loam, and one part sandy peat, making it 2 feet deep, and providing drainage. If the ground be low, the bed should be raised above the ground level, but not very much, as the plants may suffer from drought in summer. Alba plena, white; Alexina, white, striped and blotched with carmine; Donkelaarii, crimson mottled with white; Lecana superba, bright crimson; Storyi, rosy pink; and Valtevaredo, rose, are good sorts. Camellias make but little progress for a year or two after planting out. They seem to require time.

Kalmia latifolia not Flowering (*Idem*).—The Kalmias are probably grown in too moist soil; too boggy, and not sufficiently sandy. Take them up this autumn, and plant in sandy peat. That and the change of soil, from checking the vigour of the plants, will tend to insure bloom. Water freely when the plants are making fresh growth.

Old Tan (*W. H. Gullingford*).—Old tan which is so thoroughly decomposed as yours, is the same as leaf mould.

Syringing Vines after Setting (*W. K.*).—Syringing Vines after the setting of the fruit is not recommended, and for this reason—that the leaves, by maintaining a nice moist temperature in the house, may be kept equally clear of insects without water, and nearly all water, except rain water, is impure. Water often contains much chalk, which dirties and spots the berries, and very much disfigures their appearance.

Ventilating Vineries (*Idem*).—We strongly recommend abundance of air at all times, day and night, in vineries whilst the fruit is ripening, raising the temperature, if necessary, by the aid of fire heat. Grapes, above all fruits, require a brisk bracing atmosphere surrounding them whilst ripening, in order to give flavour and colour to the fruits.

Grapes Scalded (*F. H.*).—Keep the house cool, give abundance of air during the day, and keep down moisture at night.

Vines (*John Anderson*).—Graft the Muscat of Alexandria, by all means, with the kinds you require.

Rhus Cotinus Branch Broken and Propagation (*J. H. S.*).—Supporting the broken branch with a prop is good, also the tying with tar cord, but we should have placed a little moss between the bark and the cord to keep the latter from injuring the bark. The cord ought to have been untwisted, and should have been of the softest description, so as to equalise the pressure. The prop should be firm, and the branch fastened to it so as to secure it from wind. In addition to the clay poultice, which we presume you will mix with cow dung to keep it from cracking, we advise you to place a little moss over the clay to keep it moist and prevent its cracking. You will thus preserve the branch if it is not splintered, and the bark on the under side of the branch not broken. You will know by this time whether it will live or not, for if the sap cannot rise the foliage will droop. If this continue fresh all will be well. It is propagated by layers in autumn, or by suckers, which old plants often produce plentifully at a considerable distance from the stem. They should be detached in autumn, and planted in sandy soil in a warm situation.

Skeletonising Leaves (*E. S. S.*).—You will find all the information you require in an article in No. 375, June 4th, 1868.

Club Root in Cauliflowers (*Constant Reader*).—It is most frequent in dry seasons, and in ground where the Cabbage tribe has been often grown before. Sometimes the insect will attack one row, and the next will escape. Frequently change the positions of the crops; dig, trench, and expose the soil well to frost; lime it, or point-in a dressing of soot. As regards the plants, transplant them frequently, rejecting all that exhibit protuberances on the roots. A little wood ashes or soot dropped into the holes at planting, may also prove beneficial as a preventive. But when once a plant is fairly affected the best thing to do is to burn it; even if the protuberance is removed the plant rarely comes to much.

Slow-combustion Boiler (*G. Brown*).—We cannot tell what patent slow-combustion boiler you refer to, and, therefore, cannot enlighten you; but with a close-fitting ash-pit door, and a good damper in the chimney, we should have no difficulty in making any boiler in use a slow-combustion one.

Ventilating a Greenhouse (*West Cumberland*).—We do not see why in your case you should not have a table for plants at the end of the house, likewise one along the front above the soil, one at the other end, also one in the centre of the house. We think that the two ventilators in the roof in such a small house, and with front sashes opening, ought to do well, but to make sure, you might have a small ventilator at each end of the house, just under the apex of the angle formed there. In a house longer than yours, we have only ventilators in the two angles at the end, not more than a foot square, but we leave them open night and day in summer. You did right in watering your cuttings well before placing them in the frame. It is well to let the foliage become dry before shutting up. In dull weather they will need little more watering, but in a sunny day a skiff from the syringe, or a little shading will be necessary. There seems to be no reason why the Vines should not grow.

Vinery, Peach House, and Plant House Combined (*Analysis*).—It will be no drawback whatever that part of your Vine and Peach border should be inside the house; but bear in mind that your back wall will be of little use for Peaches, if you cover the roof with Vines in front. If strong rods are spur-pruned, and these are from 5 to 6 feet apart, the Peaches will do pretty well. For the same reason we would do away with the stage for plants in the centre, and be satisfied with a flat stage or table, so as not to shade the back wall. For neatness, we would place the pipes underneath the path. For effect we would place them on the top of the inside Vine border in front.

Heating a Greenhouse and Forcing Pit (*E. S. S.*).—Your piping ought to be sufficient to keep out frost from the greenhouse. It is probable that the Melons and Cucumbers suffer a little from not having quite enough surface heat in the confined space of a frame. Water will circulate even on the level, but there is no question in a length of 40 feet, if the flow-pipe rose from one end to the other, from 3 to 6 or 9 inches, and had an air pipe at the highest part, and then fell to the boiler in the same ratio, that the circulation would be better. You say you have not much of a rise to the extreme end in the greenhouse. If you have a rise at all, have you an air pipe at the highest point? If not, insert one at once. A small gas pipe will do, fixing one end in the pipe, so as to reach the water, and the other end a few feet higher outside the house. We fancy you must not have an air pipe, as with the smallest rise—say 2 or 3 inches, your pipes ought to heat rapidly with such a fire as you speak of. See to the air pipe which prevents air being confined between two bodies of water, and so becoming as impassable as a solid rock, before you sink your boiler. No doubt the sinking the boiler a couple of feet would increase the circulation, if you could do so conveniently. In all boilers, the nearer the top the flow-pipe is the better. Yours seems a long way from the top—not, perhaps, a matter of so much consequence in a conical boiler, but still of consequence, as the hottest water will always be at the top. One cause of dissatisfaction in your case, is having a short upright chimney from the boiler, and you say nothing of a damper. In this case, without a damper to throw back the heat round the boiler, we should say that more than one-half of the heat from your fuel goes up the chimney. We thus approve of the flue once round the house from the fireplace, but for a chimney we would be content to take it across the end and back, and other end to *f*. As you have pipes in front, we would place the flow-flue at back. We approve of the arrangement for Cucumbers, &c.

Erecting a Greenhouse (*James Walton*).—If the site for the greenhouse is in the line of street or road, we are of opinion you will have to give notice to the surveyor; but if not, and the greenhouse is intended to stand away in back ground, and free from other buildings, then we are of opinion you are not required to give notice. (*Sedent*).—It will be much the safest and most satisfactory both for your landlady and yourself to have a memorandum of an agreement. Then no misunderstanding can be pleaded. It is the curse of Ireland that the small tenants have merely verbal agreements, for these are not binding on either party.

Heating a Stove, Greenhouse, and Late Vinery (*Amateur*).—We cannot so well advise you, because you do not say how you mean to arrange your house. A span-roofed house will require from one-third more to twice the amount of piping needed for a lean-to of the same size, in proportion to the surface of glass exposed. A neat way of heating your range of three houses, would be to have a flow and return pipe for the 60-feet length, and that if desirable could be sunk out of sight beneath the path. As the first 20 feet next the boiler would be a stove, we would have valves so as to make the circulation complete there without going farther into the cold houses, unless when necessary. From these mains you could take what pipes were necessary. To make yourself secure, if the height at the apex is from 12 to 15 feet, you would need in the stove from 140 to 160 feet of 4-inch piping, and in each of the other places from 80 feet to 120 feet. One of the neatest modes of arranging such houses, would be to have a pathway all round, a platform at the sides, and a platform in the centre, and the piping beneath an open iron pathway.

Heating a Greenhouse (*Probo*).—You should use a 4-inch pipe, as you cannot go round the house. You cannot have anything better than a small saddle boiler for the purpose; but see that it is properly set, and is not nearer the furnace door than 15 inches.

Rape Dust (*T. J.*).—Any seed and manure merchant in any country town can supply you with Rape dust.

Pine Apples and Melons at Taunton Deane Show.—Mr. Hopper, gardener to J. H. Walmsley, Esq., The Elms, Acton, writes that the Pine Apples which Mr. Wills praises so highly, were shown by him, and not by Mr. Jarvis, Lord Bridport's gardener; also that he was second for the best-flavoured Melon.

Ready Penny Potato (*S. A. M.*).—We do not know this kind, nor its properties. The "Household Encyclopædia" was published by Kent and Co., Paternoster Row.

Stove for Conservatory (*W. J. H.*).—There is no stove we can recommend that would answer the purpose you require it for, unless it be a gas stove, and then you must have a pipe to carry off the fumes.

Forcing House (*A Subscriber*).—Do not use galvanised iron; you will lose heat. Use wooden boards with sawdust between them, which are far preferable.

Ants, to Destroy (*Sutton*).—Mix arsenic with treacle, spread it thinly on pieces of glass or earthenware, and place it near the nest, and you will soon be rid of them.

Insects in Hepbaria (*D. H.*).—A weak solution of corrosive sublimate applied over the specimens with a camel's-hair brush, will destroy the insects and prevent attacks from them, while it does not injure the colour of the flowers and leaves.

Water Weed (*I. H. S.*).—Conferva reticulata.

Names of Fruits (*Inquirer*).—Your Plum is Drap d'Or. Our readers should always send a young shoot and leaves with the fruit of Plums, Peaches, and Nectarines.

Names of Plants (*F. J., Ireland*).—Your plant is the Clover Dodder, Cuscuta trifolii. (*Tertia*).—Your plant is Centranthus ruber, which has already been figured in the "Wild Flowers." Many thanks for your offer. (*H. D.*).—Rhamnus Frangula. (*M. B.*).—Eranthemum sanguinolentum. Try the Spidanella in sand. (*Felices Amant.*).—1, Pteris cretica; 2, Adiantum cultratum; 3, Doodia lunulata; 4, Adiantum flabelliforme. (*Inquirer*).—Gnaphalium lanatum. (*Thomas*).—1, Funkia ovata; 2, Lastrea Filix-mas; 3, Spiræa ulmaria variegata; 4, Hyssopus officinalis. (*G. S.*).—We cannot name your Campanula from the scrap sent. (*J. D.*).—1, Centranthus ruber; 2, Rhus Cotinus.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending August 24th.

Date.	Barometer.		Thermometer.				Wind.	Rain in inches.	General Remarks.

POULTRY, BEE, AND PIGEON CHRONICLE.

WHITWORTH AND ROCHDALE POULTRY SHOW.

The Show of the 18th inst. proved the most successful of any yet held by this Society, the entries embracing first-rate specimens from almost every principal poultry and Pigeon breeder in the kingdom. The day was extremely favourable for an out-of-door show, being fine and sunny without oppressive heat, and we are told the receipts at the gates were unusually large.

The *Spanish* classes were remarkably good, and Mr. Brierley's cup pen was a leading feature of the Show. *Cochins* were exceedingly good, but many of the adults were in deep moult, consequently Mr. Sidgwick's excellent pen of chickens were the cup-winners. The Dark *Brahmas* were first-rate, but the Light-coloured ones did not show to advantage. The *Game* classes, though not heavy as to numbers, were of high quality, and the same remark applies with equal force to the *Polands* and *Hamburghs* generally. The Black Hamburghs were very superior. The *Dorking* and *Bantam* classes were scantily filled, and want of condition in the majority of pens was very evident. The *Turkeys*, and the whole of the water fowls, were of the highest character.

The entries of *Pigeons* were unusually large and the birds of first-rate quality.

(*From a Correspondent.*)

The *Rabbits*, divided into three classes, numbered six entries of Lop-eared, the beautiful doe of Mr. A. H. Easten carrying off the first prize; and that shown by Mr. C. Gravil was also a good specimen, though not fortunate enough to come off with honours; yet I am inclined to think she deserved a better position, more especially when the test was for the best Rabbit, not for length of ear, as is at times stated in the lists of prizes. The second prize was given to a well-marked animal from Mr. J. T. Sykes, but smaller than the others named The Silver-Greys came next, and I regret to say that some of the specimens sent appeared to have "ventured out too soon," earlier than the state of their health would warrant them; yet some good specimens were shown among the seven entries. I should here like to ask the question as to the true shade of the Silver-Grey, for the most beautifully silvered had not the good fortune to carry off the prizes, and some excellent ones were shown. The "Any other variety" class numbered eleven entries, and there was a keen contest for the first prize between Mr. Butterworth's Himalayan doe and Mr. C. Rayson's buck of the same kind. Of the two, perhaps the doe was the larger, and well marked. The second prize was given to a splendid Angora buck belonging to Mr. Rayson: his Belgian Hare Rabbit doe, the only one shown, was highly commended. Two pens were empty, and so the Rabbit fanciers were disappointed of seeing a novelty, at least by name—viz., the Belier, entered for competition. I think the Committee would do well to have some better cards for the highly commended pens, as it seems paltry to write "H. C." with pencil upon the number card of the pen.

Spanish.—1 and Cup, C. W. Brierley, Middleton. 2, H. Beldon, Goitstock, Bingley. *hc*, J. C. & E. Newbitt, Epworth; F. & C. Haworth, Newfield, Haslingden. *Chickens.*—1, F. & C. Haworth. 2, W. F. Pickard, Thorner, Leeds. *c*, P. H. Jones, Fulham.

Cochins (Cinnamon and Buff).—1 and 2, H. Mapplebeck, Moseley, Birmingham. *hc*, C. Sidgwick, Ryddlesden Hall, Keighley; W. A. Taylor, Manchester. *Chickens.*—1, Cup, and *hc*, C. Sidgwick 2, W. A. Taylor.

Any other Variety.—1, T. Stretch, Ormskirk. 2, W. A. Taylor. *c*, C. W. Brierley. *Chickens.*—Prize, C. Sidgwick Partridge).

Brahmas.—1 and Cup, J. H. Pickles, Birkdale, Southport. 2, E. Leech, Rochdale. *hc*, C. Layland, Morris Brook, near Warrington; W. Hargreaves, Bacop. *Chickens.*—1, C. Layland. 2, D. Holdworth, Broadfield, Rochdale. *hc*, H. Dowsett, Pleshey, Chelmsford. *c*, C. Layland; P. H. Jones.

Brahmas (Light).—1, H. Dowsett. 2, J. Pares, Postford, Guildford. *Chickens.*—1 and 2, J. Pares. *hc*, H. Lacy, Hebden Bridge

Game.—1, Cup, and 2, C. W. Brierley. *Cocks.*—1 and *hc*, C. W. Brierley. 2, W. Boyes, Beverley. *Chickens.*—1 and 2, J. Carlisle, Earby.

Polands.—1 and 2, H. Beldon. *hc*, W. Gamon. *Chickens.*—1 and 2, H. Beldon. *hc*, W. Gamon.

Hamburghs (Golden-spangled).—1, T. Walker, jun., Denton. 2, S. and R. Ashton, Roe Cross, Mottram. *hc*, H. Pickles, jun., Earby. *c*, F. Greenwood, Rochdale; T. Boulton, Hanford, Stoke-on-Trent. *Chickens.*—1, T. Walker, jun. 2, T. Scholes, Hollinwood, Manchester. *hc*, E. Briarley, Heywood; T. Walker, jun.

Hamburghs (Silver-spangled).—1 and Cup, H. Beldon. 2, W. A. Taylor, Manchester. *hc*, J. Fielding, Newchurch, Manchester; H. Pickles, jun. *Chickens.*—1, J. Fielding. 2, Ashton & Booth, Broadbottom, Mottram. *hc*, H. Beldon; H. Pickles, jun.

Hamburghs (Golden-pencilled).—1, S. Smith. 2, T. Wrigley, jun., Tonge, Middleton. *Chickens.*—1, H. Pickles, jun. 2, T. Wrigley, jun. *hc*, S. Lord, Healey Bottoms, Rochdale.

Hamburghs (Silver-pencilled).—1, H. Beldon. 2, Withheld. *Chickens.*—1, H. Pickles, jun. 2, H. Beldon.

Hamburghs (Black).—1, C. Sidgwick. 2, D. Lord, Stacksteads. *Chickens.*—1 and *hc*, C. Sidgwick. 2, S. Butterfield, Keighley. *c*, N. Rigg, Rochdale.

Dorkings.—1 and Cup, J. Stott, Healey, Rochdale. 2, J. White, Warlaby, Northallerton. *Chickens.*—1, T. Briden, Earby. 2, Rev. E. Bartrum, Berkhampstead. *hc*, W. H. King, Rochdale; J. White.

Any other Distinct Breed except Bantams.—1, C. W. Brierley. 2, S. H. Stott (Hondans.

Game Bantams.—1, W. Adams, Ipswich. 2, J. W. Morris, Rochdale. *Cocks.*—1 and Cup, W. F. Entwisle, Leeds. 2, C. W. Brierley.

Bantams (Any other variety).—1, H. Beldon (Pekin). 2, S. & R. Ashton.

Ducks (Aylesbury).—1, Cup, 2, and *hc*, Mrs. M. Seamons, Hartwell, Aylesbury. *c*, E. Leech.

Ducks (Rouen).—1, E. Leech. 2, W. Gamon. *hc*, D. Howarth, Broadfield, Rochdale.

Any other Variety.—1 and 2, C. W. Brierley. *hc*, T. C. Harrison, Hull.

Extra Stock.—*hc*, E. Kierby, Rochdale.

Geese (White).—1 and Cup, T. Statter, jun., Stand Hall, Whitefield. 2, E. Leech. *hc*, S. H. Stott; Rev. G. Hustler, Stillingfleet Vicarage, York.

Geese (Grey or Mottled).—1, S. H. Stott. 2, T. H. Revidge, Blackburn. *Goslings.*—1, S. H. Stott. 2, E. Leech.

Turkeys.—*Cock.*—1, E. Leech. 2, D. Howarth. *Hen.*—1, Cup, and 2, E. Leech.

Selling Class.—1, M. Cavannah, Shawclough, Rochdale. 2, W. Bamford, Marsden Lane, Harper Ley. 3, F. & C. Howarth. *c*, R. Mills (Black Spanish); W. A. Taylor; D. Howarth.

PIGEONS.

Pouters.—*Cock.*—Cup, 1, 2, and *hc*, R. Fulton, Deptford. 3, W. Gamon. *Hen.*—1, 2, and 3, R. Fulton. *hc*, R. Fulton; W. Gamon.

Carriers.—*Cock.*—1, 3, and *c*, R. Fulton. 2, F. Crossley, Elland. *hc*, R. Fulton; J. Hawley. *Hen.*—1 and 2, F. Crossley. 3, J. Hawley. *hc*, H. Yardley; R. Fulton.

Tumblers (Almond).—1, 2, and 3, R. Fulton. *hc*, J. Fielding jun. *c*, F. T. Wiltshire, West Croyden, Surrey.

BALDS OR BEARDS.—1, 2, and *c*, J. Fielding. 3, H. W. Hale, Croydon.
TUMBLERS (Any other variety).—1, J. Hawley. 2 and 3, R. Fulton. *hc*, R. Minnitt, jun, Healey Parsonage, Rochdale; R. Fulton. *c*, F. Crossley; J. Fielding, jun.
OWLS.—1, F. Crossley. 2 and 3, J. Fielding, jun. *hc*, F. Crossley; P. H. Jones.
BARBS.—1 and 3, Capt. Heaton, Eccles. 2, F. T. Wiltshire. *hc*, J. H. Ivimy, Lingfield, East Grinstead; F. Crossley; P. H. Jones, Fulham; R. Fulton; Capt. Heaton. *c*, H. Yardley, Birmingham.
DRAGOONS.—1, H. Yardley. 2, W. Gamon. 3, P. H. Jones. *c*, T. Charnley, Blackburn; W. Gamon.
TRUMPETERS.—1 and 2, J. Hawley. 3, W. Gamon. *hc*, Hudson & Burnip, Epworth; W. Gamon.
TURBITS.—1, P. H. Jones. 2 and 3, J. Fielding, jun.
JACOBINS.—1, P. H. Jones. 2, J. C. & E. Newbitt. 3, J. Hawley.
ANTWERPS.—1 and 2, H. Yardley. 3, J. Hawley.
FANTAILS.—1, W. R. Park, Abbot's Meadow, Melrose. 2, J. C. & E. Newbitt. 3, W. H. Tomlinson. *hc*, J. Walker; J. C. & E. Newbitt; P. H. Jones.
MAGPIES.—1, P. H. Jones. 2, J. Hawley. 3, E. E. M. Royds.
ANY OTHER VARIETY.—1, H. Yardley. 2, W. Massey, Spalding. 3, P. H. Jones.
SELLING CLASS.—1, F. Kay, Beverley. 2, E. Walker, Leicester. 3, W. Massey. *hc*, W. Butterworth, Rochdale; F. Kay.
RABBITS.—*Lop-eared.*—1, A. H. Easten, Hull. 2, J. T. Sykes, Rochdale. *Silver-Grey.*—1 and 2, E. E. M. Royds, Rochdale. *Any other Breed.*—1, J. Butterworth, Rochdale (Angora). 2, C. Rayson, Prestwich (Himalayan). *hc*, C. Rayson (Belgian Hare Rabbit).

The Judges of *Poultry* were Messrs. Douglas, Hewitt, and Teebay; and of *Pigeons*, Messrs. Tegetmeier and Wolstenholme.

KEIGHLEY POULTRY SHOW.

MOST favourable weather, an unusual number of entries from the most noted breeders, and an attendance of visitors beyond all precedent, rendered the Show of the 20th inst. the most successful of any hitherto held at Keighley.

The Buff *Cochins* exhibited by Messrs. Mapplebeck and Sidgwick call for especial mention, the chickens taking the cup for this variety, and Mr. Sidgwick deserves all praise for the truly excellent condition in which they were placed in competition. Mr. Brierley's extraordinary pen of *Spanish* fowls secured the silver cup, but the hen seemed to us to be somewhat "knocked-up" by over-exhibition. The same gentleman also obtained the silver cup for the best pen of *Game* fowls with very well-shown Brown Reds. In *Hamburghs* Mr. Beldon was the most fortunate exhibitor with birds of the highest merit; and Mr. Sidgwick's excellent Black Hamburghs were equally worthy of the highest praise. *Polish* chickens were very good and well shown. Game *Bantams* were for the most part considerably out of feather. The classes for *Ducks* and *Geese* were especially good, and the "Variety" class of Ducks was the object of general attraction. In this class the varieties taking prizes were the Whistling Ducks and the Ruddy Shell Ducks. Mandarins, Teal, Carolina, and Bahama Ducks were also in this competition.

The *Pigeons* were of very superior quality, and the general attractiveness of this portion of the Exhibition was evident from the assemblage of visitors which absolutely thronged this portion of the Exhibition.

The *Rabbits*, though not so strong numerically as the Committee could have desired, were admirable specimens, and the competition was good in each of the four classes devoted to them. The Angora Rabbits were particularly first-rate.

COCHIN-CHINA (Buff).—1 and 2, H. Mapplebeck, Woodfield, Moseley, Birmingham. *hc*, C. Sidgwick, Riddlesden Hall, Keighley; W. A. Taylor, Manchester. *Chickens.*—Cup, 1, and *hc*, C. Sidgwick. 2, W. A. Taylor.
COCHIN-CHINA (Any colour).—1, W. A. Taylor. 2, C. W. Brierley, Middleton. *hc*, — Crossley, Bloomfield, near Halifax. *Chickens.*—1 and 2, C. Sidgwick.
SPANISH (Black).—1, C. W. Brierley. 2, H. Beldon, Bingley. *hc*, J. C. and E. Newbitt, Epworth. *Chickens.*—1, H. Beldon. 2, W. & F. Pickard, Thorner, Leeds. *c*, J. H. Booth, Silsden; J. Berry, Silsden.
HAMBURGH (Silver-pencilled).—1 and 2, H. Beldon. *Chickens.*—1, Cup, and 2, H. Beldon. Extra 3, H. Pickles, jun, Earby. *hc*, J. Steel, Branshaw Moor; H. Pickles, jun.
HAMBURGH (Golden-spangled).—1, H. Beldon. 2, S. & R. Ashton, Mottram. *hc*, H. Pickles, jun. *Chickens.*—1, W. Driver, Morton Banks. 2, H. Beldon.
HAMBURGH (Golden-pencilled).—1, E. Clayton, Morton Banks. 2, S. Smith, Northowram. *hc*, H. Beldon. *Chickens.*—1, H. Beldon. 2, J. Wilkinson, Northowram. *hc*, S. Smith.
HAMBURGH (Silver-spangled).—1 and 2, H. Beldon. *hc*, W. A. Taylor. *Chickens.*—Cup, 1, and 2, H. Beldon. Extra 4, H. Pickles jun. *hc*, W. Bairstow, Bingley. *c*, G. Mitchell, Keighley; W. Bairstow.
HAMBURGH (Black).—1 and *hc*, C. Sidgwick. 2, J. Smith, Gilstead. *Chickens.*—1, Cup, 3, and 4. C. Sidgwick. 2, T. Fawcett, Baildon. *hc*, S. Butterfield, Keighley. *c*, W. Green, Keighley.
POLISH.—1 and 2, H. Beldon. *Chickens.*—1, J. Bowker, Keighley. 2 and *hc*, H. Beldon, Bingley. *c*, W. Gamon, Chester.
DORKING.—1, T. Briden, Earby. 2, G. Andrews, Turford. *Chickens.*—1, T. E. Kell, Wetherby. 2, T. Briden, Earby.
GAME (Red).—1 and Cup, C. W. Brierley. 2, H. Jowett, Idle. *hc*, E. Aykroyd, Bradford. *Chickens.*—1 and Cup, H. Jowett. 2, J. Fortune, Morton Banks. *hc*, J. Carlisle, Earby, Skipton. J. Pearson, Bradford.
GAME (Any other variety).—1 and Cup, H. M. Julian, Hull. 2, H. Jowett. *hc*, G. Noble, Staincliffe. *Chickens.*—1, Cup, and 2, T. Dyson, Halifax.
ANY OTHER DISTINCT BREED.—1, E. Leech, Rochdale. 2, J. Smith, Long Lee. *Chickens.*—1, E. Leech. 2, J. J. Malden, Biggleswade. *hc*, J. J. Malden; M. Scott, Idle. *c*, S. H. Stott, Rochdale.
GAME BANTAM.—1, J. Crosland, Wakefield. 2, W. F. Entwisle, Leeds. *hc*, G. Noble; W. Greaves, Bradford. *Chickens.*—1, G. Noble. 2 and *hc*, J. Crosland. *c*, W. F. Entwisle.
BANTAM (Any other distinct breed).—1, H. Beldon. 2, T. C. Harrison, Hull. *hc*, S. & W. Clapham, Keighley. *c*, S. & R. Ashton; S. H. Stott. *Chickens.*—1, J. H. Riley, Keighley. *c*, T. C. Harrison, Hull; R. B. Riley, Halifax.
DUCKS (Rouen).—1, J. Dixon, Bradford. 2, J. Newton, Silsden. *hc*, J. H. Booth, Silsden; E. Leech, Rochdale; J. Dixon.
DUCKS (Aylesbury).—1, E. Leech. 2, no competition.
DUCKS (Any other variety).—1 and 2, C. W. Brierley. *hc*, S. & R. Ashton; J. Dixten; T. C. Harrison; W. Greaves.
GEESE.—1 and 2, E. Leech, *hc*, H. Crossley; S. H. Stott.
SELLING CLASS (Any variety).—*Cock.*—1, J. Bowker, Keighley. 2, F. H. Hawood, Haslingden. *hc*, J. Berry. *c*, J. Smith; C. W. Brierley, Middleton; R. Longbottom, Bingley. *Hens.*—1, J. Bowker. 2, J. H. Booth. *hc*, W. Johnson, Idle; H. Beldon; J. Berry, Silsden; J. Carlisle, Earby. *c*, H. Wilkinson, Skipton; J. Smith, Allerton.

PIGEONS.

POUTER.—*Cock.*—1, 2, and *c*, E. Horner, Harewood. 3, W. Gamon. *Hen.*—1, 2, and 3, E. Horner.
CARRIER.—*Cock.*—1, J. Thompson, Bingley. 2 and 3, E. Horner. *c*, J. Hawley, Bingley. *Hen.*—1, J. Hawley. 2, H. Smith, Skipton. 3 and *c*, E. Horner.
TUMBLERS (Almond).—1, J. Fielding, jun., Rochdale. 2, J. Hawley.
TUMBLERS (Mottled).—1, J. Hawley. 2, J. Fielding, jun.
BALDS OR BEARDS.—1, 2, and 3, J. Fielding, jun. *c*, E. Horner.
OWLS.—1, 2, and *c*, J. Fielding, jun. 3, T. Eggleston, Halifax.
TURBITS.—1 and 3, E. Horner. 2, J. Fielding, jun. *c*, T. C. & E. Newbitt.
JACOBINS.—1 and 3, E. Horner. 2 and *c*, J. Thompson.
FANTAILS.—1, 2, and *c*, J. Hawley. 3, T. C. & E. Newbitt.
BARBS.—1, J. Firth, Dewsbury. 2 and 3, J. Fielding, jun. *c*, E. Horner.
DRAGOONS.—1, S. Smith, Bradford. 2, J. Thompson. 3, T. Smith. *c*, T. Smith; J. Thompson.
TRUMPETERS.—1, J. Hawley. 2 and 3, E. Horner. *c*, J. Firth.
MAGPIES.—1 and 2, E. Horner. 3, J. T. Lishman, Girlington. *c*, J. Hawley.
ARCHANGELS.—1, J. Thompson. 2, H. Yardley. 3, J. Booth. *c*, S. & R. Ashton.
ANY OTHER BREED.—1 and 3, E. Horner. 2, J. Fielding, jun. *c*, J. Hawley.
SELLING CLASS (Any variety).—1 and 2, E. Horner. 3, J. Fortune, Morton Banks.
RABBITS.—*Long-eared Buck.*—1 and *hc*, T. Ingham, Leeds. 2, C. Gravil, jun., Thorne. *Doe.*—1, C. Gravil, jun. 2 and *c*, T. Ingham. *hc*, A. H. Easten, Hull. *Any other Variety.*—*Buck.*—1, A. H. Easten. 2, T. Rawstron. *hc*, L. Sharp, Keighley; S. M. Smith, Keighley. *Doe.*—1, A. H. Easten. 2, E. Driver, Morton Banks. *hc*, L. Sharp.

The Judges were for *Poultry*, Mr. E. Hewitt, Eden Cottage, Sparkbrook, Birmingham, and Mr. R. Teebay, Fulwood, Preston; for *Pigeons*, Mr. W. Smith, Halifax.

DEANE POULTRY SHOW.

THIS Show was held on the 19th inst., and though the entries were not very numerous, some good specimens were shown. Mr. Leech, of Rochdale, would doubtless have taken several prizes had he not sent a cock and hen for each pen, instead of one cock and two hens as required by the rules.

SPANISH.—1, C. W. Brierley, Middleton. 2, T. C. & E. Newbitt, Epworth
DORKINGS.—1, W. H. King, Rochdale. 2, W. Parr, Particroft.
GAME.—1, C. W. Brierley. 2, R. H. Ainsworth, Moss Bank, Bolton. *Cock.*—1, C. W. Brierley. 2, A. Smith, West Leigh.
COCHIN-CHINA.—1, C. W. Brierley. 2, T. Teasdale, Longworth, Bolton.
BRAHMAS.—2, M. Platt, Deane (Dark).
HAMBURGHS.—*Golden-pencilled.*—1 and 2, W. Parr. *Silver-pencilled.*—1, J. Platt. 2, W. Parr. *Golden-spangled.*—1, W. Perr. *Silver-spangled.*—1 and 2, J. Fielding, Newchurch, Mancheater.
POLANDS.—1, J. Partington, Leigh (Silver-spangled). 2, W. Gamon, Chester.
ANY OTHER VARIETY.—1, D. Lord, Stacksteads, Manchester (Black Hamburghs). 2, H. Wyndham, Wawne, Beverley (Crêve-Cœurs).
GAME BANTAMS.—1 and 2, W. F. Entwisle, Leeds.
BANTAMS (Any other variety).—1, N. Platt, Dean (White Rose-comb Bantams). 2, R. H. Ainsworth.
DUCKS.—*Aylesbury.*—1, H. S. Woodcock, Wigan. *Rouen.*—1, C. W. Brierley. 2, W. Gamon. *Any variety.*—1, S. H. Stott, Rochdale. 2, C. W. Brierley.
TURKEYS.—1, S. H. Stott.
PIGEONS.—*Carriers.*—1 and 2, J. Chadwick. *Tumblers.*—1, H. Yardley. Birmingham. *Owls* (English).—1, A. Jackson, Heaton. 2, W. Gamon. *Pouters.*—1 and 2, W. Gamon. *Fantails.*—1, T. C. & E. Newbitt. 2, J. Chadwick. *Dragoons.*—1, D. B. Bromilow, Over Hulton. 2, H Yardley. *Antwerps.*—1, H. Yardley. 2, W. Markland, Deane. *Any other Variety.*—1 and 2, J. Chadwick (Black and White Barbs). *Extra Stock.*—2, D. Bromilow (Dragoons).

The Judges were Mr. S. Fielding, Trentham, and Mr. T. H. Ridpeth, Outwood Hall, Hanford, near Manchester.

POCKLINGTON POULTRY SHOW.

(From a Correspondent.)

THIS was held on the 18th inst., when the following awards were made:—

GAME (Black-breasted and other Reds).—1, W. Boys, Beverley. 2, O. A. Young, Driffield.
GAME (Any other variety).—1, W. Boys. 2, W. Bearpark, Ainderby Steeple, Northallerton. *Chickens.*—1, C. Kelsey, M. Weighton. 2, W. Bearpark.

Spanish.—1, W. Bearpark. 2, G. Holmes, Driffield. *Chickens.*—1, G. Holmes, 2, Mrs. J. Cook.

Dorkings.—1, D. White, Driffield. 2, G. Holmes. *Chickens.*—1, W. J. Holster, York. 2, O. A. Young.

Cochin-China.—1, G. H. Radmine, Whitby. 2, S. Robson, Brotherton. *Any other Variety.*—1, — Smithson, Manor House, Barmby. 2, J. Appleton, Pocklington. *Chickens.*—1, R. Dawson, Beverley. 2, Mrs. Dawson.

Brahma Pootras.—1, O. A. Young. 2, Lady Muncaster, Warter Priory. *Chickens.*—1, J. Taylor, Barmby Moor.

Hamburghs.—1, G. Holmes. 2, W. Bearpark.

Hamburghs.—1 and 2, G. Holmes. *Chickens.*—1 and 2, G. Holmes.

Farmyard Cross.—1, O. A. Young. 2, G. Holmes.

Game Bantams.—1, J. Dugglehy, Driffield. 2, G. Holmes.

Bantams (Any variety).—1, T. C. Harrison, Hull. 2, G. Holmes.

Single Cocks—*Game.*—1, W. Boys. 2, W. English, Pickering. *Spanish.*—1, T. Robson. 2, O. A. Young. *Dorking.*—1, D. White. *Cochin-China.*—1, R. Dawson. 2, G. Holmes. *Hamburghs.*—1, G. Holmes. 2, J. Webster. *Bantam.*—1, W. Gilson, Pocklington. 2, G Holmes.

Ducks.—1, M. Harrison, Warter. 2, O. A. Young. *Ducklings.*—1, M. Harrison. 2, O. A. Young.

Ducks (Any variety).—1, T. C. Harrison, Hull. 2, W. J. Hulster York. *Ducklings.*—1, Miss Singleton, Pocklington. 2, Mrs. Bolderson, Beilby.

Geese.—1, W. J. Hulster. 2, O. A. Young. *Goslings.*—1, T. Croft. 2, M. Harrison.

Turkeys.—1, O. A. Young. 2, W. J. Hulster.

Guinea Fowls.—1, T. Croft. 2, O. A. Young.

Pigeons.—*Pouters or Croppers.*—1, S. Robson. 2, W. Bearpark. *Tumblers*—1, F. Kay, Beverley. 2, C. N. Lythe, Cottingham. *Barbs.*—1, H. Yardley, Birmingham. 2, C. Anton, York. *Jacobins.*—1, R. Fleming, Hull. 2, H. Yardley. *Fantails.*—1 and 2, C. N. Lythe. *Trumpeters.*—1, S. Robson. 2, C. N. Lythe. *Owls*—1, F. Kay. *Turbits.*—1, C. N. Lythe. 2, Pickering and Marshall, Driffield. *Carriers.*—1, W. Campoey, Beverley. 2, H. Yardley. *Nuns.*—1, C. N. Lythe. 2, H. Yardley. *Any other Variety.*—1, H. Yardley. 2, C. Anton.

Rabbits.—*Longest Ears.*—1, J. Appleby, Pocklington. 2, J. Staveley, Sibthorpe. *Buck.*—1, T. Spink. *Doe.*—1, R. Graygen. 2, J. Sellers.

WORCESTER POULTRY SHOW.

This Show opened on the 24th inst., and will close to-day. The competition was restricted exclusively to chickens, and considering the time of year, it has rarely been our privilege to meet with its equal in general quality. The arrangements, as might be anticipated, under the eye of Mr. Holland, need no improvement, and the courtesy and the desire of that gentleman to meet the wishes of all exhibitors, claim the highest approval.

The *Game* classes might certainly have been stronger, the bulk of these varieties being somewhat out of feather. The Grey *Dorking*, on the contrary, was one of the most meritorious of classes; and the Buff and Partridge *Cochins* were of unusual excellence. Of Dark *Brahmas* there was one of the best and heaviest entries in the Show, exceeding the anticipations of most poultry exhibitors. The Light-coloured Brahmas were good, but there was not a large entry. All the *Hamburghs* were excellent, the Blacks, Silver-pencilled, and Silver-spangled being especially so. *Game Bantams* were mostly the worse for moulting, but many pens from our first-rate breeders were to be found among the winners. Laced Sebright Bantams were a weak entry, and, unfortunately, some of the best birds arrived too late for competition.

Of *Geese*, *Turkeys*, and *Ducks* we do not wish to see better entries; they were all first-rate. The class for any other variety of Ducks was unexpectedly a weak one, a pen of excellent Buenos Ayrean being first, and a pen of common Teal second.

As regards the weather, nothing could be more favourable, and there was a very large attendance of visitors. Messrs. Turner's pens left nothing to be desired in the way of improvement, and every attention was paid to the poultry.

CHICKENS.

Game (Black or Brown-breasted Reds).—1, W. H. Cooke, Stanford-on-Teme, Worcester. 2, C. Chaloner, Steetly, Whitwell, Chesterfield. 3, T. Dyson, Halifax.

Game (Black or Brown-breasted Reds).—1 and 3, S. Matthews, Stowmarket. 2, W. Jones, Worcester. *hc*, F. Oreton, Walsall *c*, E. Shaw, Plas Wilmot, Oswestry; H. C. & W. J. Mason, Drighlington, Leeds.

Game (Duckwings and other Greys and Blues).—1, Mrs. E. Winwood, Worcester. 2, C. Chaloner.

Game (Duckwings and other Greys and Blues).—1, H. C. & W. J. Mason. 2, C. Chaloner. *hc*, G. S. Sainsbury, Devizes; E. Winwood. *c*, J. Cope, Barnsley; Miss L. Winwood, Worcester.

Game (Any other variety).—1, J. Pares, Postford, Guildford. 2, W. Griffith, Worcester.

Game (Any other variety).—1, H. C. & W. J. Mason. 2, G. & C. Furness, Accrington.

Dorkings (Coloured, except Silver-Grey).—1, Rev. A. K. Cornwall, Bencombe, Dursley. 2, L. Patton, Hillmore, Taunton. 3, Miss E. Whittington, Preston Hill, Henley-in-Arden. *hc*, J. Smith, Sbil jngles Park, Sussex; F. Parlett, Great Baddow, Chelmsford; Miss E Whittington; Rev. E. Cadogan, Walton Parsonage, Warwick. *c*, E. Shaw; J. F. Liebert, Wellesbourne Hall, Warwick.

Dorkings (Silver-Grey).—1, D. Campbell, M.D., Brentwood. 2, J. Watts, Hazelwell, Hall, King's Heath, Birmingham.

Spanish.—1, Tonkin & Tuckey, Bristol. 2, F. James, Peckham Rye, Surrey. 3, W. R. Bull, Newport Pagnell. *c*, F. James; H. & S. Cooper, Walsall.

Cochin-China (Cinnamon and Buff).—1, C. Sidgwick, Ryddlesden Hall, Keighley. 2, D. Young, Leamington. 3, Mrs. Allsopp, Hindlip Hall, Worcester. *hc*, T. Stretch, Ormskirk; C. Sidgwick; W. A. Taylor, Manchester; Mrs. Allsopp. *c*, J. Cattell, Bristol Road, Birmingham; F. W. Rust, Hastings.

Cochin-China (Partridge and Grouse).—1 and 2, C. Sidgwick. 3, H. Lingwood, Martlesham, Woodbridge, Suffolk. *hc*, T. Stretch; E. Shaw. *c*, G. Lamb, Compton, Wolverhampton.

Cochin-China (Any other variety).—1 and 2, A. J. E. Swindell, Heathland, Kinver, Stourbridge. *hc*, A. P. Steedman, Bromsgrove.

Brahma Pootra (Dark).—1 and 3, H. B. Morrell, Caermawr, Radnorshire. 2, H. Lingwood. *hc*, H. B. Morrell; Hon. Mrs. A. Baillie Hamilton, Edgcomont, Woburn; Mrs. Hurt, Alderwasley, Derby. *c*, Rev. J. Bowen, Llangorse, Talgarth; H. Dowsett, Pleasley, Chelmsford. J. K. Fowler, Aylesbury; Mrs. Burrell, Stoke Park, Ipswich.

Brahma Pootra (Light).—1, H. Dowsett. 2, T. A. Dean, Morton-on-Lugg, Hereford. *hc* and *c*, J. Pares.

Hamburghs (Black) —1, C. Sidgwick. 2, J. M. Kilvert, Ludlow.

Hamburghs (Gold-pencilled).—1, H. Pickles, jun., Earby, Skipton. 2, W. Pierce, Hartford, Northwich, Cheshire. *c*, J. Watts.

Hamburghs (Silver-pencilled).—1 and *c*, Mrs. Allsopp. 2, H. Pickles, jun.

Hamburghs (Gold-spangled).—1, T. May, Wolverhampton. 2, Miss C. E. Palmer, Lighthorne, Warwick.

Hamburghs (Silver-spangled).—1, H. Pickles, jun. 2, W. Stephens, Gloucester.

Any Distinct Variety, not included in the above Classes.—1, Miss E. Williams, Henleys, Berrlew, Montgomeryshire. 2, Mrs. Seamons, Hartwell, Aylesbury (Crève-Cœur). 3, H. M. Maynard, Holmewood, Ryde, Isle of Wight (Houdans). *c*, J. B. Masefield, Ledbury (Houdans); W. O. Quibell, Newark (Houdans).

ADULT BIRDS.

Game Bantams.—1, J. Crosland, jun., Wakefield. 2, W. F. Entwisle, Leeds. 3, W. Adams, St. Clements, Ipswich. *hc*, J. Crosland; W. F. Entwisle.

Bantams (Laced).—1, H. Draycott, Humberstone, Leicester. 2, Countess of Winterton, Shillinglee Park, Sussex.

Bantams (Black or White).—1, S & R. Ashton, Mottram. 2, J. Elgar, Osmanthorpe Hall, Newark.

Turkeys —1, L. Patton. 2, Mrs. Allsopp.

Geese.—1, Mrs. Seamons. 2, J. K. Fowler. *hc*, S. H. Stott, Rochdale; Mrs. Allsopp.

Ducks.—*Aylesbury* —1, J. K. Fowler. 2, Mrs. Seamons. 3, E. C. Phillips, Fenyroch, Brecon. *hc*, J. K. Fowler. *c*, Mrs. Seamons. *Rouen.*—1, L. Patton. 2, W. Stephens, Gloucester. 3, F. Parlett. *hc*, J. K. Fowler. *c*, Mrs. E. G. Norris, Hatchford Parsonage, Cobham, Surrey.

Ducks (Any other variety).—1, Miss Clifton, Whittington Worcester. 2, S. & R. Ashton.

The Judge was Edwd. Hewitt, Esq., of Eden Cottage Sparkbrook, near Birmingham.

MEIGLE POULTRY SHOW.

The following awards were made at this Show, which took place on the 18th inst.:—

CHICKENS.

Dorkings.—Cup, P. W. Ogilvy, Ruthven. 2 and *hc*, G. Allan, Balbary.

Spanish.—1, J. Fergus, Polmont. 2, Mrs. Anderson, Meigle. *c*, T. Raines.

Brahmas.—1 and 2, P. W. Ogilvy. *c*, J. W. Morrison; D. Gellatly, Meigle.

Game.—1, P. W. Ogilvy. 2, J. Douglas, Clumber.

Cochin-China.—2, J. M'Donald, Carnoustie.

Hamburghs.—1, G. Caithness.

Bantams.—1, T. Raines. 2, P. W. Ogilvy.

Any other Variety.—1, Miss Anderson, Meigle.

Any Variety (Adult).—1, J. Douglas. 2, P. W. Ogilvy. *vhc*, T. Raines. *Chickens.*—1, P. Symon. 2, J. M'Donald. *c*, T. Raines.

Selling Class.—1, P. W. Ogilvy. 2, Mrs. Anderson. *c*, Miss Brown, Pensicbill.

Ducks.—1, P. W. Ogilvy. 2, Mrs. J. Douglas.

Geese.—1, Mrs. Barclay, Simprin. 2, Mrs. J. Douglas. *c*, W. Hendry, Aberdeen.

Turkeys.—1, Miss A. Kinloch. 2, Lord J. F. G. Hallyburton.

LOCAL.

Dorkings.—1 and 2, J. Allan. *c*, A. Bruce. *Chickens.*—1, A. Bruce. 2, D. Gellatly. *hc*, G. Allan.

Spanish.—1, W. Thomson. 2, Mrs. Anderson. 3, J. Cree. *Chickens.*—1 and 2, Mrs. Anderson. 3, W. Thomson.

Any other Variety.—1, J. Munro, Ruthven. 2, J. Witton, Ruthven. 3, Mrs. White, Whins, Ruthven. *c*, G. Brown. *Chickens.*—1, 2, and 3, D. Gellatly. *c*, D. Crichton, Ruthven.

Ducks.—1, D. Gellatly. 2, G. Cuthill. 3, G. Allan. *Ducklings* (Selling Class).—1, A. Bruce. 2, Mrs. Kidd. 3, Mrs. Duncan.

Selling Class.—1 and 3, W. Simpson. 2, R. Simpson, Cardean.

Pigeons.—1, D. Gellatly (Barbs). 2, D. Anderson, Meigle. 3, P. Henderson (Fantails).

KNARESBOROUGH POULTRY SHOW.

This Show, held on the 24th inst, was not so large as several of those which took place in previous years, though in quality some of the birds were faultless.

The most noticeable birds were the *Spanish* hens in the first-prize pen, and those in the winning pens of *Hamburghs*. The *Dorkings*, *Game*, and *Cochins* were moderately good. The winning *Pigeons* were very good.

The day was very fine, the Show well supported, and another year the Committee will, doubtless, be able to so far augment the prize list as to secure a larger show.

The following is the prize list:—

Cochin-China.—1, — Barnes, Thirsk. 2, W. & F. Pickard, Thorner. *c*, G. Holmes, Great Driffield; J. Walker, Haya Park, Knaresborough. *Chickens.*—1, — Barnes, Thirsk. 2, Miss Lord, Starbeck.

Dorkings.—1, A. C. Thompson, Kirby Hall, York. 2, J. Walker. *Chickens.*—1, A. C. Thompson.

Spanish.—1, W. & F. Pickard. 2, G. Holmes. *hc*, W. & F. Pickard. *Chickens.*—1 and 2, W. & F. Pickard. *hc*, G. Holmes; A. C. Thompson.

GAME (Any variety).—1 and 2, J. Watson, Knaresborough. *hc*, G. Holmes; J. Johnson, Starbeck. *Chickens.*—1, J. Watson. 2, J. Johnson.
HAMBURGHS (Golden-spangled).—1, J. Walker. 2, G. Holmes. *hc*, B. Marshall, Knaresborough. *Chickens.*—1, J. Walker.
HAMBURGHS (Golden-pencilled).—1, J. Walker. 2, G. Holmes. *c*, F. Horsman, Boroughbridge. *Chickens.*—1 and 2, J. Walker.
HAMBURGHS (Silver Pheasant or Spangled).—1, J. Walker. 2, G. Holmes. *c*, A. C. Thompson. *Chickens.*—1, J. Walker. 2, T. Cliff, Knaresborough.
HAMBURGH OR CRITTEPRAT (Silver-pencilled).—1, J. Walker. 2, G. Holmes. *Chickens.*—1 and 2, J. Walker.
BRAHMA POOTRA.—1 and 3, F. Powell, Knaresborough. 2, F. Horsman. *hc*, A. C. Thompson; F. Powell; J. Walker. *Chickens.*—1, 2, and *c*, F. Powell. *hc*, A. C. Thompson.
GAME BANTAMS (Any variety).—1, J. Pennington, Thirsk. 2, G. Holmes. *hc*, J. Walker; A. C. Thompson; F. Powell.
BANTAMS (Any other variety not previously mentioned).—1, F. Powell. 2, G. Holmes.
GEESE.—1 and *hc*, J. Walker. 2, J. Joy, Preston Bottoms.
DUCKS (Aylesbury).—1, A. C. Thompson.
DUCKS (Any other breed, not Aylesbury).—1, C. Graham, Aldborough. 2, J. Walker.
TURKEYS.—1, J. Joy.
GUINEA FOWLS.—1, J. Walker.
BARNDOOR FOWLS.—1, G. Holmes.
EXTRA STOCK.—1, C. Walker.

PIGEONS.—*Tumblers.*—1 and 2, J. Mason, Boroughbridge. *Fantails.*—1 and 2, J. Mason. *hc*, J. Watson, jun., Knaresborough. *c*, J. Walker. *Croppers.*—1, J. Watson, jun. 2, J. Walker. *Jacobins.*—1, J. Mason. 2, J. Walker. *Carriers.*—1 and 2, J. Watson, jun. *hc*, J. Mason.

Mr. Hutton, of Pudsey, was the Judge.

WOODSOME POULTRY SHOW.

THE fourteenth annual Exhibition of the Woodsome Society took place on the 18th inst. It was a good Show, exceedingly well attended, and the quality of the *Poultry* and *Rabbits* first-rate, but the *Pigeons* were not so good. The champion prize was closely contested by the first-prize Brown Red Game and the first-prize Golden-spangled Hamburghs, the latter winning by one point only.

DORKINGS.—1 and 2, J. T. Beaumont, Greenhead, Huddersfield.
SPANISH.—1, Burch & Boulter, Sheffield. 2, H. Beldon, Bingley.
COCHIN-CHINA.—*Cinnamon or Buff.*—1 and *hc*, C. Sidgwick, Ryddlesden Hall, Keighley. 2, J. H. Dawes, Mossley Hall, Birmingham. *Any other variety.*—1, J. White, Whitley, Netherton, near Wakefield. 2, J. Heeley, Hepworth, Holmfirth. *hc*, C. Sidgwick.
GAME (Black-breasted or Brown Red).—1, E. Aykroyd, Bradford. 2, G. White, Denby. *hc*, A. Senior, Riley, Kirkburton. *c*, H. Roberts, Highgate Lane, Lepton.
POLANDS.—1 and 2, H. Beldon.
BRAHMAS.—1, G. H. Walker, Slaithwaite. 2, C. Layland, Morris Brook, near Warrington. *c*, J. T. Beaumont; J. Battye & Co., Hillhouse, Holmfirth.
HAMBURGHS.—*Gold-pencilled.*—1, H. Beldon. 2, W. Parr, Patricroft, Manchester. *Gold-spangled.*—1, H. Beldon. 2, J. White. *hc*, J. Rollinson, Lindley, Otley. *c*, G. Haigh, Hogley Green, Holmfirth. *Silver-pencilled.*—1 and 2, H. Beldon. *Silver-spangled.*—1 and 2, H. Beldon. *c*, J. Bradbury, Bradshaw, Anstonland.
GAME BANTAMS.—1, J. Walker, Bradford. 2, G. Noble, Staincliffe. *hc*, W. F. Entwisle, Leeds; G. Noble; R. Armitage, Lepton; A. Senior; S. Binns, Spring Gate, Kirkburton; W. Greaves, Bradford. *Any other Variety.*—1, G. White, Denby. 2, H. Beldon. *hc*, J. Walker, Halifax.
CHICKENS (Any breed).—1, J. Bradbury. 2, C. Sidgwick. *hc*, J. T. Beaumont; S. Binns, Spring Gate, Kirkburton; R. Ellis, Junction, Saddleworth. *c*, J. Smith, Kirkburton.
DUCKS.—*Aylesbury.*—1, J. T. Beaumont. 2, B. Kaye, Honley. *hc*, J. North, jun., Huddersfield. *Rouen.*—1, J. White. 2, James Crossland, Huddersfield. *hc*, C. Sidgwick. *c*, S. H. Stott, Rochdale; James Crossland.
TURKEYS.—1, S. H. Stott. 2, James Crossland, Huddersfield.

PIGEONS.—*Carriers.*—1, James Crossland. 2, B. Shaw, Stirley, Berry Brow. *Pouters.*—1, James Crossland. 2, A. Broughton, Lockwood. *Tumblers.*—1 and 2, J. Hawley, Bingley. *Fantails.*—1, J. Hswley. 2, J. Hey, Brockholes. *c*, J. H. Sykes, Elmwood, Huddersfield. *Jacobins.*—1 and 2, James Crossland. *Trumpeters.*—1, J. Hawley. 2 and *hc*, J. H. Sykes. *c*, James Crossland. *Barbs.*—1, J. Hawley. 2, James Crossland. *hc*, J. H. Sykes. *Common Dovecote.*—1, L. Armitage. 2, J. H. Sykes. Equal 2, James Crossland. *c*, H. Sugden, Woodsome Lees.

RABBITS.—*Buck.*—1 and *hc*, T. Ingham, Leeds. 2, C. Gravil, Thorne. *Doe.*—1 and *hc*, T. Ingham. 2, C. Gravil.

The Judges were Mr. William Cannan, Bradford, and Mr. E. Hutton, Pudsey, Leeds.

LONG SUTTON POULTRY SHOW.—We have received the prize schedule of the Long Sutton Poultry Show, to be held on the 6th and 7th of October next, the entries closing on September 25th. It is one of the most liberal that have been issued for some time. Twelve silver cups are offered for competition, nine of which are of the value of five guineas each, and three of three guineas each. There are separate classes for young and old birds, consequently these cups cannot be monopolised by either young or old birds, each competing separately in their respective classes, and the competition is open to any part of the kingdom. There are also offered four other silver cups, restricted to local exhibitors. The money prizes are on a no less liberal scale. The list includes thirty classes for poultry, eighteen classes for Pigeons, and two for Rabbits. The Judges appointed appear by name in the prize schedule, and are Mr. Hewitt, of Birmingham, for poultry, and Mr. Tegetmeier, of London, for Pigeons.

THE INTRODUCTION AND PROPAGATION OF LIGURIANS.

(*Continued from page* 114.)

HAVING therefore, either by the purchase of a stock, or by the introduction of one or more queens, succeeded in obtaining the true breed, it is probable that most persons will expect to be enabled at once to propagate the pure Italian race; it is at least certain that I myself did so, and it took some time and a very considerable amount of rather unpalateable experience to undeceive me. It is true that if the Ligurian stocks be so exceptionally strong in early spring as to breed drones well in advance of every black colony within a radius of three to four miles, and young queens can be reared before any black drones are produced, such queens will have every chance of obtaining pure fertilisation. Although, singularly enough, I was so fortunate as to obtain this result with the first queen I ever reared, subsequent experience has satisfied me that success in the first attempt with only one Italian colony is so rare, that it is far better to devote the first season to furnishing every stock in the apiary with a Ligurian queen, multiplying queens at the same time as far as may be deemed desirable, but paying little or no heed to the character of their impregnation. For reasons which need not be entered upon here, but which have been already specified by me in discussing the subject of parthenogenesis in the honey bee, all these queens, although they may, and most of them probably will, breed a mixed worker progeny, will in the next and succeeding years breed only pure Italian drones, by the multitude of which the chances of a true impregnation will in the ensuing season be so much increased that the purity of the majority of young queens of the second year is not improbable; whilst if care be taken to keep all the stocks well up to the mark, success in the case of early-bred queens becomes nearly certain. During this second season, therefore, all doubtful queens of the first year should be weeded out and replaced by those of the current year.

Queens may also be bred in the autumn, and when all black drones have disappeared can scarcely fail of true impregnation, if a sufficient number of Italian drones can be preserved, and if the weather be warm enough.* For this purpose the usual drone massacre may be deferred almost indefinitely in one or more stocks by removing their queens. It is, however, in this case necessary to recruit the population, and at the same time to revive the courage of the bees by the occasional addition (or rather substitution of full brood-combs for empty ones), of combs filled with worker brood; whilst it is also essential promptly to destroy or remove any young princesses that may be raised, since not only will all the drones be speedily exterminated in the event of a princess becoming fertile, but the workers sometimes become so impatient of their presence under such circumstances, that a partial, or even an entire, massacre may take place even before the juvenile monarch has been able to avail herself of their services.

The Köhler-Dathe process, the revelation of which was anticipated in this country by my valued friend and correspondent, "R. S.," whose contributions to "our Journal" are unfortunately but too infrequent, can scarcely be of much use when the season is somewhat advanced, and so many old stocks and second swarms of common bees with young queens are worrying their drones that these persecuted unfortunates are incessantly on the wing, but up to and during the month of June, it will probably be found valuable in securing the pure impregnation of Italian queens. Mr. Köhler says the operation "is founded on my observation, that during many fine forenoons and afternoons the air is still warm enough for queens to fly out when drones usually have not commenced flying or have ceased to take wing. Until, therefore, the young queens become fertilised, we must compel the Italian queens and drones to go forth at such times as the German drones cannot possibly be abroad. The time during which drones are on the wing seldom extends with us to later than 4 or 5 P.M. If, therefore, we have one or more colonies with young queens which we know to a certainty have not yet been fertilised, we place these hives for three, four, or five days in a perfectly dark and cool cellar, and with them also the stock which contains the Italian drones. Whenever a very warm and sunny day occurs

* Dzierzon states that a temperature of above 70° is required.

we watch the German stocks until the drones have ceased their flight. As soon as this occurs we restore the hives containing the Italian queens and drones to their accustomed stands, and set them at liberty, after giving to each a cupful of liquid honey. The queen and drones being ardent, and having been unable to fly for days, the bees excited by the honey and their previous confinement become so eager after flight, that all play as if mad, and fertilisation follows. We must, however, be careful to return to the cellar in the evening every colony the queen of which has not been seen to return with the signs of a successful flight, and repeat the process until it is certain that the desired result has been obtained. This is essential, because it is well known that under ordinary circumstances some queens take flight several times before they succeed in meeting with a drone."

Dr. Preuss proposes still further to control the queen, and his method may, perhaps, be considered an improvement on the Köhler-Dathe process. He advises imprisoning the young queen on the fourth or fifth day of her existence, either under a wire pipe-cover, or by dividing off a part of the hive by means of a wire gauze partition, and then in the afternoon of the eighth or ninth day of her existence, and after the common drones have ceased to fly abroad, take out one or two combs with pure drones on them, stand them in the neighbourhood of the queen's hive, and then releasing her on a comb, rest it against the front of her hive, and permit her to take wing from it. He states that "as soon as the queen perceives the drones buzzing about her, she usually in less than a minute soars into the air, whence in from a quarter of an hour to an hour she returns fertilised to the hive, in order after three days to commence egg-laying." The combs are, of course, returned to their respective hives when the queen and drones have taken flight; and if the operation be not at once successful, the queen must be again imprisoned, and the process repeated on subsequent days until the desired result be attained.*

Mr. Köhler also describes another method which may be valuable where common hives are in use, and by which, as he expresses it, he obtains natural swarms by an artificial process, and can at the same time with one good Ligurian stock, Italianise a dozen colonies with the least possible trouble. The process is as follows:—"We take a hivo from which a swarm has just issued, and put it in the place of another very populous colony. After nine days, by means of the population received from the removed hive, it will certainly swarm again. If it is now shifted to the stand of another strong stock, it will, after two or three days, swarm again. We continue this process as long as we can hear queens piping in the hive of an evening. Under favourable circumstances, we may in this way obtain ten or twelve swarms, as the first hive supplies the queens and the others the bees. If, therefore, we have one or two Italian stocks, and feed them well early in the spring—say from the 20th of March, especially if they are well supplied with pollen, we may be sure that these hives will swarm first. By transposing them in this way with German stocks we shall obtain swarms with Italian queens and German bees."†—A Devonshire Bee-keeper.

(To be continued.)

REMOVING BEES TO THE MOORS IN HOT WEATHER.

I was sorry to see, in page 136, that "B." had been so unfortunate as to lose his bees in removing them to the heather. If he had followed my instructions in the Journal of July 21st, and September 1st, 1863, he would not have had to deplore the death of his bees; but they would have been now repaying him for taking them to such luxuriant pastures, where hundreds of tons of honey and wax are annually lost to the nation from want of collectors.—William Carr.

* Dr. Preuss's article appeared *in extenso* in No. 425 of "our Journal."
† The text of Mr. Köhler's article may be referred to in No. 386 of "our Journal."

OUR LETTER BOX.

Sickle Feather in Tail of a Brahma Pootra (*H. L.*).—The feather you sent is not a disqualification. It often arises from age. The older the cock the longer and larger the tail, and it often comes white at the points. Nothing justifies pulling out a tail. If the birds are properly judged tampering is sure to be detected, and that is more fatal than any excess of feather.

Silver-spangled Hamburghs Dark-combed (*C. P.*).—The nature of the diet you are giving your birds is unsatisfactory. Give them an entire change. Withdraw for a time all the maize, rice meal, grains, &c., and give them good barley meal made into dough, and thrown down to them on the ground. If the change should produce no effect in appearance, try them with one meal-a-day of stale bread soaked in ale.

Fowls Dying (*Bubo*).—We imagine your fowls have poison among the refuse wheat. You describe the symptoms of it. It is more than probable some of it has been dressed with arsenic for sowing. There is nothing remarkable about the stones; they are the grinders that enable the fowl to digest the food. When found in large numbers they are an indication of indigestion or discomfort. Wheat has a tendency to swell in the crop, and as soon as it is uncomfortably distended the patient flies to the water and drinks to excess; this causes the wheat to swell more, and then by instinct the bird picks up stones in the vain hope of getting rid of the discomfort in a natural way. All these symptoms would be aggravated tenfold if there were any arsenic. It would cause intense thirst and burning heat. If the intestines are examined there will probably be bright red spots always in a bleeding state, and these will account for the pain the birds suffer. Discontinue the "refuse wheat;" feed on good oat or barley meal mixed with milk; give them lettuces that have run to seed; withhold all other food save that which they pick up. If you have any severe cases now, shut up the birds, purge freely with a table-spoonful of castor-oil every day for three days, give milk to drink, and if necessary administer it with a syringe; afterwards give Bally's pills, and adopt a nourishing and slightly stimulating diet.

Feather-eating Fowls (*J. G. M.*).—We are afraid we can tell you of no plan by which you can prevent the French fowls from eating each other's feathers, if they are at all confined. We do not find they do it when at liberty. We have tried all we knew in medicine and food without success.

Rearing Young Pheasants (*Young Countryman*).—You will have no difficulty whatever in keeping your Pheasants. They have arrived at an age when they cause no trouble. You must enclose a place, on grass if possible, about 30 feet by 20, with hurdles made of split fir or other wood. The hurdles should be 14 feet high, and the laths forming them 1 inch apart. They should be fastened to upright poles, to which they should be attached. This is all that is necessary, as the birds require no shelter of any kind, and in such a place ten Pheasants may be kept as long as it is wished. Their food should be barley. It is necessary to cut one wing before they are put in such a pen; and as it may be desired to turn some out, and to keep in others, you should select the best and strongest, cut their wings, and put them in. Let the others fly away as soon as they will. As a rule, they take to roosting in the hedges, they go higher and higher till they reach the trees; in the same way they become less punctual at feeding time, till they absent themselves altogether. If you keep up only four birds you will require a pen only half the size of that we have mentioned. You may change their food at times by giving Indian corn or dough made of barleymeal, and slaked with milk or water. They should have fresh water always by them. There is an excellent work on Pheasants, published by Baily, Mount Street, price 1s.

Guinea Fowls (*G. McF.*).—We do not in England know so much of Guinea Fowls as we should. Much of our treatment of them is guesswork. It is believed, and we believe, they are monogamous, yet a person whom we can trust, says, he keeps a cock and four hens, and all the eggs are good. We believe they pair as strictly as Partridges. It is difficult to tell the sex. We tried to keep pairs, but we never did, and the eggs were very bad. We were once shooting on a wild track, where no house was in sight, and there was none within a quarter of a mile. The pointer stood in a patch of gorse. It was long before we could find the cause; when we did, we sprung a Guinea Fowl; she had forty-three eggs under her. None of them had been sat upon. When the hen wants to sit, she will go to the eggs and remain there. We have recounted the above anecdote only to show how prone they are to steal their nests, and it is more than likely your hen has a corner somewhere ready furnished.

Young Pigeons Diseased (*Pigeon*).—The causes of roup are cold and damp, and what are similar—draughts, and the cure is warmth. Considering the season is summer, we doubt if the complaint is roup, but rather canker, for the cure of which in young Pigeons we quote from a very old author:—"Take a half-pint phial and fill it three-parts full of the best vinegar, and drop into it as many drops of spirit of vitriol as will make it sufficiently pungent, which may be ascertained by trying it on the tongue a few times; sweeten it with a little honey, which will make it adhere to the throat, shake them well together, and take a feather and anoint the inside of the throat of the bird affected two or three times a-day, and in general a cure will be accomplished; hang the phial up in the loft where it will be ready for future occasions, as I do not perceive that the specific loses its virtue by keeping."

Australian Ground Parrakeet (*Old Subscriber*).—Canary seed and dry crumbled bread appear to suit this bird best. In constipation we should try bread and milk if the bird would eat it, or give four drops of castor oil. We should advise trying the bird with various kinds of food in order to save it.

Books (*J. B. B. N.*).—"Profitable Bee-keeping," by the Rev. P. V. M. Filleul, M.A., is published by the Society for Promoting Christian Knowledge, and may be obtained through any bookseller.

Black Stock Becoming Liourianised (*B. K.*)—There seems no doubt that the young queen of the whilom black colony has mated with a Ligurian drone, which causes her to produce a mixed progeny.

Driving and Uniting (*G. Scott*).—We should keep the stock hive and the second swarm if, as is most probably the case, the latter has filled its hive with comb. You will thus secure a harvest of fine honey in new combs, and may hope to leave young queens at the head of the two remaining colonies. It is well to remove one queen if it can be managed, preserving the younger or the larger of the two. The mode of uniting which you describe often answers completely, but on the other hand it sometimes fails altogether. The best plan is to drive both lots of bees into an empty hive, and then induct them into the one which they are permanently to occupy. You will find much valuable information on this and other points in Mr. Woodbury's articles on "Utilising and Uniting Condemned Bees," which appeared in Nos. 356, 357, 358, and 369 of our new series. The honey harvest ceases in our locality as soon as the fine weather breaks up in July, and if you can utilise the unhatched brood perhaps this is the best time for uniting. If not, you must balance matters as best you can between the destruction of brood and the possible waste of honey until, perhaps, about the end of September, when breeding comes nearly to a standstill.

From observations taken near London during the last forty-two years, the average day temperature of the week is 70.3°; and its night temperature 47.3°. The greatest heat was 85°, on the 8th, 1865; and the lowest cold 28°, on the 7th, 1855. The greatest fall of rain was 0.70 inch.

ALPINE STRAWBERRIES.

IN flavour and size of fruit these are not commendable, but though the flavour is not high, and the size what we must call small, they afford a plentiful supply, and of longer continuance than any other kind of Strawberry; indeed the Strawberry season may be said to be over when the Alpines are coming in plentifully, and on that account alone they have a claim to our attention. And they have other claims. First, the flavour is peculiar—a sort of acidity that is not distasteful, but refreshing, more so than that of any other kind of fruit, always excepting the Cherry. Secondly, the birds do not attack them so much as other fruits; very few at most seem to satisfy them. Thirdly, they are the only kinds that can be depended on for autumn fruiting. I have had plants that began bearing in July producing fine fruit up to Christmas in a mild autumn and winter. The Perpetual Pine has lost its perpetual or autumn-fruiting qualities, at least, so far as I have experience, and the fact is confirmed by others; hence the value of the Alpine as an autumn and successional fruit to the kinds generally cultivated. Fourthly, a dish of Red or White Alpines set up with their own leaves is not less pretty than a pile of huge Goliaths. I think them very pretty, and even for ornament alone a good addition to the dessert.

The best plants are those raised from seed. They are more vigorous, less liable to suffer from drought, are more continuous-bearing, and more to be depended on for autumn supply. The best plants I ever had were from seed distributed by the Royal Horticultural Society ten or eleven years ago. Plants from runners are of too weak growth, the fruit after the first picking becoming small, and the runners they produce do not keep up the successional and autumn supply. With some sorts of Alpine Strawberries propagation by runners must be practised, as it is a ready mode, and all cannot have seed; besides, in seed-saving, the finest and best fruit must be sacrificed; but considering that plants from seed are the best, and bear the finest fruit both in summer and autumn, I strongly recommend this mode of propagation. In sowing seed we do not run the same risk of perpetuating plants which yield but small fruit, or are shy bearers, as we do when taking runners from a bed in which there are various degrees of vigour, size of fruit, and continuance of bearing. The plants propagated by runners seem to become weaker, and for anything I know may sink to an equality with the plants on a hedge bank. By taking the fruit of the most vigorous and most continuous-bearing plants, and sowing, we obtain plants fully equal to the parents; in no case have I known them inferior, for it is not species which run into all sorts of forms, and give so many useless ones, though there are at times great results, but the cross-breds. Not only do Alpine Strawberries come true from seed, but every generation shows a marked improvement in the majority of the offspring, and it is by this progressive improvement that I hope to see the Alpine yielding fruit of the size and flavour of such kinds as Black Prince, if not of Cockscomb. Autumn production and increased size of fruit from plants raised from seed, are not peculiar to the Alpine Strawberry alone; the autumn-fruiting Raspberry is influenced in the same way. The seedlings are in most instances finer than the parent, none, or few, producing inferior fruit.

The Alpine Strawberry succeeds best in soil overlying gravel, limestone, or in those medium textured loams that are neither heavy nor light, and have an open subsoil from which superfluous water passes away freely.

In light, open soils, Alpine Strawberries succeed with copious waterings in dry weather after they come into flower, and during bearing; but in heavy wet soils they do not thrive, at least, they do not with me. The plants are apt to go off in winter, and in soils of this kind I have found a raised bed advantageous. It may be formed of any kind of rough material, marking out a space about 8 feet wide, and raising, about a foot high in the centre, a mound of stones or gravel, which is covered with a foot thick of soil. This may consist of two parts loam, neither heavy nor light, enriched with one part of well rotted manure—old cow dung is best. All round I place bricks on edge, alternately headers and stretchers; and when I have formed a row all round, I have cavities which are filled with soil level with the upper sides of the bricks. I then place another row or tier of bricks as before, and so on to the top, or until the bricks from both sides meet in the centre of the mound. It may seem strange to employ bricks for such a purpose, and it may be thought that a raised mound would answer just as well. It does not, however; for the plants cannot be so well watered, the water running away too quickly by the surface, and this is prevented by the brick terraces, and the bricks keep the fruit from damping, as it is apt to do in autumn from the frequent rains. The spaces for the plants formed by the bricks are filled with soil, and one plant is planted in each. The situation should be open, and the ends of the bed ought to be north and south. In such a bed the plants continue bearing until late in autumn. Alpine Auriculas in heavy soils are quite at home in beds of this description, and Parsley thrives where, from the wetness and coldness of the soil, it is often not to be had in winter when most wanted. In most soils, however, such contrivances are not required, all that is needed being a good trenching, and manure liberally worked in. A border or bank facing south is not good, the plants grow best on an east border; on a north border they succeed very well for summer fruiting, and an open spot with the lines running north and south answers very well.

The seed should be sown in February or the beginning of March in a shallow box or pan, well drained, and filled with a compost of two parts loam and one part leaf mould, covering lightly with fine soil. Place the pan in a gentle heat of from 70° to 75°, keep moist and close until the seedlings are up, then admit air, and keep them near the glass; when large enough to handle, prick them off in shallow boxes or pans, employing a light loam, enriched with one-third leaf mould. They should stand about an

inch apart. Return them to the frame, and keep them close and moist, shading from bright sun for a few days until they recover, and are growing freely; then give them plenty of air, harden them well off by the beginning of May, and plant them out where they are to fruit.

In planting, three lines may be placed in a 4-feet bed at 14 inches apart, and the plants 1 foot from each other in the lines. The outside lines may be 6 inches from the edges, and 1-foot alleys being left, they will be 2 feet from the opposite outside lines of each bed. They may also be planted in lines 18 inches apart, and the plants 1 foot apart in the lines, putting in two lines, and then allowing 2 feet between these and the next two lines, which space will serve as an alley, affording access to the plants for gathering the fruit and watering. The plants should be lifted carefully, preserving the roots as far as possible, and a good watering given, which should be repeated in dry weather. Before the dog-days, the intervals between the rows should every year be mulched with short manure or leaf mould. This to a great extent prevents evaporation, furnishes a good material for the runners to root in, and watering carries down a portion of the nourishing matters of the top-dressing to the Strawberry roots. The better the plants are attended to with water the better they will grow. They will not bear much the first year, though in autumn they may afford a tolerably good supply.

For autumn fruiting in the first year, the seed ought to be sown at the end of January or beginning of February in heat, the seedlings pricked off when large enough, forwarded in heat, and hardened off by the end of April, when they should be planted out.

When the plants commence blooming, slates or tiles should be placed between the rows to prevent the dampness of the soil in autumn causing the fruit to decay. There is another advantage in the slates, besides preserving the fruit—they become heated by the sun's rays, and the fruit acquire a better flavour. The runners ought to be allowed to grow; they should not be cut off as they appear, for from them we hope for fruit in autumn, as well as from the parent plants.

Instead of raising plants from seed for autumn fruiting, runners of the previous year may be planted in March or the beginning of April, and treated like the seedlings, only they are not put under glass. For summer fruiting, and continuing the supply until autumn, the runners should be planted out when they become well rooted, and during the year in which they are produced by the parent plants. The trusses of bloom ought to be pinched off as they show on those planted in spring to furnish late autumn fruit, until August, as by allowing them to fruit before they become established we keep them weak, unable to give more than a moiety of autumn fruit.

Having the plants now established from seed or runners, in March I cut away all the runners not rooted, point the soil between the lines and around the plants, and give a top-dressing of rotten manure fully an inch thick. When the plants are coming into bloom give a similar top-dressing, and afterwards water copiously in dry weather. There is no necessity for putting down slates in summer or in the second year, for the crop will come in from July to the end of August. When the gatherings are becoming smaller—the plants are very sluggish in August, as most Alpines are from the drought—I take away any runners where too crowded, but not many, and top-dress again, putting the top-dressing neatly round the plants and runners, and give a good soaking of water then and every third day as long as the weather continues dry. I place some slates between the rows by the end of September, destroying some runners which would have fruited, no doubt, but for the slates; but any loss from this cause is compensated for by the fruit being prevented from decaying. The result the second year is plenty of fruit in July and August, the supply slackening a little at the end of the month; and from September to Christmas, if the weather is mild, I have fruit—not a dish every day, but very often, and might have a dish every day if a sufficient number of plants were grown.

In the third year trim and top-dress in March. Leave a good many runners at that time between the rows, and water well after they come into bloom. They will bear an immense number of fruit—small, but the finest of all for preserving, as they keep their form so well, and they are particularly desirable for glasses on the table. It is hard to tell whether the red or white are the more beautiful. After they have borne all the fruit they will in the third year, break up the bed, and plant the ground with anything except Strawberries, the most exhausting crop I know. To keep up a supply we must sow or plant every year, or not more seldom than every alternate year.

The following varieties, besides the Red and White Alpine, are the best—viz., Blanche d'Orléans, white; fruit larger than the White Alpine, which it must supersede. Brune de Gilbert, dark red, nearly black; it fruits abundantly in autumn, but is small. Galande, dark red; an abundant bearer, perhaps the best-flavoured Alpine.

If blight appear it is a sign that the watering is insufficient, or runs off by the surface without wetting the soil, as water often does on slopes. In this case holes should be made with an iron bar or rod, and the water given gently; by the exercise of a little patience the soil may thus be made thoroughly moist. The blight or mildew disappears when the soil becomes moist, and a good wetting overhead on the evenings of hot days will wash it off the fruit, and keep the latter from becoming deformed, and from not swelling; indeed, if the mildew be left to itself the blooms turn blind. Plenty of air, water, and a broiling sun are the delight of the Strawberry.

It may not be known that seedlings grown in 6-inch pots, placed in a frame early in November, always afforded air, but protected from frost, if removed to a light, airy house in December, and set on a shelf near the glass, will fruit in winter. Their handsome fruit and pretty foliage render them fine objects for table decoration, the red variety contrasting well with the white. The plants should be grown in partial shade until the end of August, have all blooms picked off, and then be potted in 6-inch pots, layering the first runners just within the rim, as a fringe all round. Set the pots in the full sun, and water well. The plants may be had in bearing throughout the autumn, and at any time you like by picking off the flowers six weeks before you want them. Remove all runners but those wanted for the fringe.—G. Abbey.

NOTES ON ROSES.

During the last few weeks I have had several exceedingly fine flowers from Roses grafted as standards on the Briar in March last, many of which are now coming into bloom again, and by the end of the autumn, should nothing unforeseen occur, will form excellent bushy heads. I am led to make the above remark from the observations contained in some letters I received after the appearance of my article on Rose-grafting in the open air on the Briar (see Vol. XVI., page 178), as the quickest and best method for obtaining good and lasting standard Roses, many persons expressing an opinion that if grafted instead of budded the flowers would deteriorate. This I have found not to be the case, but, on the contrary, some of the weaker kinds grow much better, and the top of the Briar being closed over, no insects make their way in and eat down into the pith of the stock, as with those budded.

I am fully aware that the stock on which a plant or tree is budded or grafted will, and does, often alter the colour of the flower or flavour of the fruit of the scion, and I have an instance of this. Two standard Roses (both budded) of Lord Raglan, have been producing quite distinct flowers in the way of colour; the flowers of one tree being of a deep reddish-coloured purple, while those of the other had much blue or violet. In all other respects they are similar. Possibly had these two trees been grafted, the grafting might have been urged as the cause. However, what I want to make known at the present time, is the perfect success of grafting Roses as standards on the cleft or wedge principle, which I have heard has been, and still is doubted.

My Roses have done well this year so far, thanks to Fowler's Insecticide, two syringings of which effectually cleared them of the aphis. I have also used it with some success for the yellow fungus on other trees.

Amongst my newer varieties, I purchased Maréchal Neil. This is the only Rose I can do nothing with at present. I have tried it on its own roots, on the Briar, on the Manetti, in the border, and against a south wall, and still it eludes my utmost endeavours to make it grow. Tea Roses, as a rule, do very well with me, but Maréchal Neil does not; it loses its foliage, and finally dies. I mention this, as I find others, like myself, have lost their plants. I shall try it once more worked on the Gloire de Dijon as a stock. This is my last hope.

As a white—a clear good white, I am much pleased with Boule de Neige, the habit is good, the petals thick, and it is of good form, though small, and with me it has been much admired. Xavier Olibo, Victor Verdier, Alfred Colomb, Duke of

Wellington, John Hopper, Rushton Radclyffe, Charles Lefebvre, and the old but not to be despised Baronne Prévost, have been grand this year.—HARRISON WEIR, *Weirleigh.*

ORCHARD-HOUSE FAILURES.

I THINK it redounds to the credit of orchard-house cultivators that they have given vent to so few jeremiads such a confessedly disastrous season as this. The absence of complaints argues a considerable amount of patience, and this is just as it should be. "The husbandman waiteth for the precious fruit of the earth, and hath great patience for it." But how much more patience is requisite when we have to wait two whole years instead of one! How largely have orchard-house growers had occasion to draw upon their stock of "sufferance"—the badge of all their tribe—during a season which, to the majority of them, has proved barren of all fruitful results! They may truly say with Mark Tapley, that there is some credit in being jolly under such depressing circumstances. Should, however, the disappointment have proved too keen to any brother amateur when surveying his fruitless boughs, to admit that he has escaped what he may deem a very pardonable amount of chagrin, I would hope to administer balm to his spirit by the suggestion of two considerations. The first is, others are rowing in the same boat. Disappointment has attended human endeavour time out of mind. If even Solomon, after having made him gardens and orchards, and planted trees in them of all kinds of fruits (and oh, what gardens, what orchards must his have been!), yet acknowledged when he looked on these, that behold all was vanity and vexation of spirit, surely we, who cannot boast of his wisdom, who live in a colder climate than he enjoyed, and who, even in glass houses, have tenfold more chances against success than he had, should not be surprised at a failure for once in our lives, or suffer ourselves to be too much cast down by unavoidable misfortune. The second consideration is one that applies to young cultivators rather than those who have possessed orchard houses for several years. Depend upon it, Nature has done the best thing that could have possibly happened to you. You know you never would have had the heart to have stripped your young trees of their embryo fruits. But they will bear all the better another year. Remember how honest Will Shakespeare represents John of Gaunt as saying—

> "Teach thy necessity to reason thus—
> There is no virtue like necessity:
> Think not the king did banish thee,
> But thou the king."

Which I parody thus—

> Think not that Nature haulks thy fond pursuit,
> But thou thyself hast wisely thinned thy fruit.

Would any one of us surpass Solomon in wisdom? Then let him meet reverses without sharing his vexation of spirit.

Honour, all honour, to those who, in spite of sullen skies, have retained their own serenity of spirit—who, in the face of a dearth of Peaches and Nectarines this year (but not of Apricots; with me they have been plentiful), have themselves brought forth the precious fruits of longsuffering and of patience—who have prosecuted their daily routine of orchard-house labour, pinching, root-pruning, syringing, and watering, just the same as though their trees were well laden with fruit, in anticipation of better luck next year. And honour to those also who, in a manly spirit, have candidly owned to a failure this year, yet fully assured that the well-established principles of orchard-house culture are not in fault, but that the general failure is to be attributed to circumstances beyond control, and so exceptional as to be likely to occur only once in a lifetime. My friends come to me and say, "Well, Mr. So-and-so, how does your orchard house answer this year?" I reply, "Fishermen sometimes come home with empty creels, and I confess to a failure this year." "Indeed!" say they, somewhat superciliously, "but we thought that glass insured a remunerative crop." "As a general rule," I rejoin, "it does. But there is an exception to every general rule. Have you considered," I ask, "what we have had to contend against? Last summer our trees fainted under a long continuance of tropical heat, very prejudicial to the proper ripening of the wood, and causing likewise a scarcity of water." And then (remembering how old Socrates used to floor opponents by asking embarrassing questions—questions the obvious answers to which proved the case against them), I proceed to inquire, "How would you like, after a long day's grouse-shooting in this August temperature, to get no sleep? or, just as you were comfortably snoozing off, to be awakened by an alarum in your ears, or some other horrid sound, and after such a night as that to have to renew your sport for another sultry day, as though nothing had happened to mar your rest?" "Not at all," responds my friend. "Well, then," say I, "that is just what our poor trees have had to do. Not only had they to endure last summer's baking, but root action was kept up to a late period in the autumn—in other words, they could not go to sleep. They had no rest all last winter; or, whenever they did get a ghost of a nap, some fine genial sunny morning, when it ought to have been snowing, woke them up again. Then, poor things! they did all they could. They put forth a rich profusion of bude and blossoms, and I fully believe they quite intended keeping the fair promise which those blossoms indicated, even to their own prejudice, but a cold ungenial spring set in, and those smiling blossoms could make no progress. They remained on the trees, looking very pretty, but almost in a dormant condition, for a longer period than usual, during all which time the bleak east wind prevailed; the consequence being, that when they should have set the blossoms fluffed off, as my brother, writing from Horsham, classically expressed it. It was not that the frost penetrated the glass and nipped the blossoms—no fear of that; but the cold depressing weather lasted so long, that the blossoms sank under it, the flower perished, and so the fruit failed."

I believe you invite your correspondents to record their own experience as regards orchard-house culture, and so I will just add a line to say, that although upon the whole I must class myself with those who have failed to bring much fruit to perfection this year, yet I can show some very fine samples of fruit, especially on one or two of my triple cordons, which have been treated according to directions furnished in Mr. Bréhaut's invaluable work on that system, the perusal of which I cannot too strongly recommend. My crop of Grapes is very satisfactory. Many bunches have now coloured. I cover them in muslin bags, which will protect them from wasps, but not from rats. Rats, by-the-by, would make excellent judges of the flavour of Grapes. They always attack the best first; and I cannot blame them, for I know I should do just the same had I been born, as Sam Weller would have said, in that station of life. I have a Peach tree on a west wall outside my house, the fruit of which has in two former years carried away the first prize at a fruit show. It has fifty Peaches on it, which promise to be remarkably fine. I did not give any protection to this tree last spring, but by a thorough fumigation destroyed all the aphides. I am convinced that an early fumigation is one of the chief things to be attended to both in-doors and out, but is very often omitted until too late. Some of my trees, I am sorry to say, are afflicted with mildew, and this is a disease which at present baffles my skill.

In my miniature orchard I have a fair crop of Apples, Pears, and Plums. With regard to the latter, it is quite a sight to see the lady birds preying upon the innumerable aphides. They go at it *con amore*, and I only wish that butchers' meat (at this season when it wo'n't keep), were as tender as those delicate morsels seem to be—I mean the aphides, not the lady birds. Some ignoramus the other day in a newspaper spoke of "the plague" of lady birds. Plague, indeed! How little he knew with what exuberant feelings of joy the Hop-grower welcomes an immigration of those red-jacketed beetles, or with what exquisite delight an orchard-house grower observes them making a raid upon the "varmint" that infest his trees. "They seem jolly hungry," my boy said to me as he viewed them through a microscope. "Yes," I said; "they must have fasted when they came across the sea." I hope they may long continue to enjoy the same hearty appetite, and that they may be troubled with no dyspeptic consequences.—A CONSTANT READER, *Herts.*

LOUISA SMITH TRICOLOR PELARGONIUM.

"AFTER all, is there anything better for a bed amongst the Tricolors than Mrs. Pollock?" is a question often asked in a very triumphant tone by those lovers of old times who always like to disparage novelties. It has been difficult to answer it, inasmuch as the high price at which these Pelargoniums are sold, has prevented persons from trying them in a mass. I am, however, now enabled to assert, that in every respect Mrs. Pollock is distanced by Louisa Smith; the latter is brighter in the yellow margin, smoother in leaf, and twice as good a grower, and I would advise all who wish to have a good Tricolor

bed to plant it. It will beat Lady Cullum, for, brilliant as the latter is, there is too much dark brownish crimson in the leaf to make it as effective; it wants lightiug up.—D., *Deal.*

LANCASHIRE GOOSEBERRIES.

The Gooseberries I sent are not show berries, but are all from the garden of James Matthews, of Hinsted, between Littleborough and Rochdale, and are very fair specimens of the average of fruit in a well-cared-for Gooseberry garden. The grower took a copper kettle with some from Companion, and 9s. with some from Garibaldi, on Saturday, July 31st, at the first Gooseberry show of the season. It was held in a public-house in Milnrow, Tim Bobbin's birthplace. The highest prize given there is a pan, the second a kettle, and so on through a great number of decreasing money prizes. I think I am right in saying that four colours are shown, and eight kinds in each. The winner of the pan can only take six other prizes. The best show of the season, one open to all England, is held at "The Falstaff," a public-house in Market Place, Manchester. The competitors all meet there on August 7th, I believe at noon, and each opening his box, the specimens are measured and weighed before all; they are then topped and tailed, to ensure their not being shown again, and put in open dishes, and the public are admitted. The berries after the show here are the property of the landlord. It seems that all these shows are held at public-houses, and in other places begin at four in the afternoon.

The trees are pruned of their middle branches, and trained so as to allow a free current of air amongst the branches, which are bent or tied, so as to be uniform in growth, all buds near the base of the stem being nipped off. The berries are early thinned according to the fancy and ambition of the owner, some taking almost all off; others, as in the case of the grower of these specimens, merely thinning them sufficiently to prevent the wind knocking the berries against each other. Some grow them in little glass globes with a very small hole, into which the Gooseberry when quite small is introduced, but these are few; some grow them under shades of various sorts; all protect them from the north wind. With some kinds of berries the old tree is chosen for the show fruit, with others the young; in all the shoots of the last year bear the best fruit. Some kinds require stronger manure than others, but all that is used must be well rotted. Some use blood; but as the roots grow wide and not deep, such rich manure as would be used for the Vine or the Plum is to be avoided. Books are written on these shows, which are only to be had by the grower. The real Gooseberry showers do not send their fruit to mixed shows, nor is the prize fruit to be bought.

I could not get the show Gooseberries at the show of August 7th, so send some of the largest of the rejected that I could obtain at the show. I sent old John over to see it, and his account was racy. I asked him if it was a sort of thing I could have gone to. "Yes," he said, "it was as husht as a chapel. A route of folk cowered down on benches all round th' room, and the landlord tappit on the table if onybody stirred, and then he and the judges weighed and measured the berries in things on purpose, and turned them all sei, and if there was a spot, or a mark, or aught it would naw do. One man had brought one weighed 39 pennyweights, and were 7 inches round, but it were just a bit burst. The biggest wiout blemish were 27 pennyweights, and 5 inches. Man as took that had a route more same sort. I said, 'I'm a man as knows a Gooseberry when I sees it, and what's fair for it; win you sell ony?' He says, 'Well, you're a man as I never sot ees on afore. I've friends who'll want all as there is, or I'd have let you have some.' Another chap said, 'You shaw ha all I have for half a sovereign' I said, 'Dun yo think I'm a foo, mon?' But if you could ha seen show berries, missus, you wouldn't have lookit at these." I said, "Did you get any fresh information about the growth? Did that man with the big one tell you how he managed his?" "I'll tell yo what, missus, if you want to get aught out of a gardener, yo win get a mon wi wits and ma him fun wi driuk afore he'll tell yo aught. Biggest I ever had were 6 inches, and weighed 35 pennyweights and a bit over."

That is John's account as truly as I can render it, John's tongue loosened by moderate imbibing.

The year is a bad one for Gooseberries. The largest are grown in Nottinghamshire, the next in Yorkshire and Cheshire, the next in Lancashire, I think, since these last are from Cheshire. The first I sent were from about the coldest Gooseberry garden I know of, the last were not so very much better. I put them by the side of Green Gages and other Plums, and the Gooseberries were the largest. John adds, "Landlord had a room o' purpose, boards as white yo mit a eaten on them, and glass cases for berries. He would ha let yo have some wi ā' pleasure in the world, he said, but they mon hide there for volk to see, till Tuesday or so," by which time I think they would not be worth much, judging from the specimens at the Horticultural Society's Fruit Committee.—V.

BEGONIA WELTONIENSIS.

Those who examined the new and rare plants at the last Regent's Park Show could not fail to notice this hybrid Begonia in the collection exhibited by Messrs. A. Henderson and Co., of the Pine Apple Nurseries, and which was awarded a first-class certificate of merit. I had previously purchased the plant under the name of Begonia Clarkei; and I now wish to call attention to it as being one of the most useful, if not the most lovely, of the varieties that I am acquainted with. Its foliage is a bright glossy green, while contrasting favourably with this is the almost blood-red colour of the stem and veins of the leaves. The bloom is in trossee of four or five bright rose-coloured flowers, coming freely from every shoot. The plant bears stopping well, and produces vigorous shoots at every joint; but without this stopping it has a dwarf compact habit of growth, its foliage is very attractive, and the plant thrives as well in small as in large pots.

The decorative qualities of this plant, which can be brought to perfection in a warm greenhouse temperature, make it a most valuable addition to the stock of a large class of cultivators; for many of these have been prevented, through the amount of heat required, from enjoying the beauty of Begonias. I tried a few plants for winter flowering in the conservatory last season, and was so much pleased with it as to be induced to grow it largely for that purpose during the coming winter. It would be difficult to find a more suitable one as a dinner-table or drawing-room plant. It is easily kept through the winter, and my plan is to throw away all but half a dozen plants, which may be taken out of the pots and stored away, like Dahlia roots, in dry earth on a damp bottom until wanted in spring. They should then have all the old soil shaken from them, be potted, and placed in any structure affording an intermediate temperature, when the stools soon put forth shoots.

If a stock of plants be wanted, make cuttings of these, and strike them in sandy peat soil, sifted fine, in a gentle heat. After they are rooted pot them singly in 4-inch pots, using for a compost two-thirds turfy loam, the remainder peat, silver sand, and dried cow dung; this dung must be sifted through a fine-meshed sieve. Of course if larger plants are wanted potting and stopping must be attended to, but they will grow into very fair-sized and useful specimens in 6-inch pots. When growing, they like a good share of moisture both at the roots and branches.

I have not been without a number of this useful plant in bloom for more than twelve months, and its beautiful foliage and flowers have performed no unimportant part in the decoration of flower-stands, vases, and épergnes. From its usefulness and easy culture I expect it to become a general favourite. It is very cheap, being catalogued at 5s. per plant.

I have an idea that Begonia weltoniensis will be useful in the subtropical department of the flower garden, and for outdoor vases or rustic baskets. Should anyone be trying it in this way, I hope to hear more about it at the end of the bedding season.—Thomas Record, *Hawkhurst, Kent.*

SUPPLY FROM A KITCHEN GARDEN.

I can fully sympathise with "A Perseverino Gardener's" complaint in page 125 respecting the limited space of ground from which he is expected to supply a family of eleven persons, for I am placed under similar circumstances.

My garden is 103 yards in length and 28 yards in width, running north and south, and its numerous disadvantages are death to many crops. On the east side and two ends are walls, on the west side a fence. Within the boundary there is a walk 5 feet wide which takes up a large extent of ground. The soil, too, is a light sandy loam, very shallow, and resting on chalk and gravel. On the east side, 35 feet from the wall, is a wood of some hundreds of acres. On the west side, at 30 feet from the fence which divides the kitchen garden from the pleasure grounds, stand on the lawn several huge Elm trees, thrusting

their roots into the kitchen garden, and especially into the Asparagus bed. The family and servants whom I have to supply are ten in number, and with company the average number supplied with fruit and vegetables through the summer has been eighteen persons. How is it possible for a gardener with so many disadvantages to give satisfaction to employers, who expect the same delicacies in small gardens as in those of much greater extent, with position and soil good, and every means favourable to securing abundant crops? This is a point I should like to see urged with proprietors, and possibly if an improvement could be effected gentlemen would not hesitate. These improvements would generally be enlarging the garden according to the wants of the family, making the soil good where required, and if practicable, felling all huge trees that are too near the garden.—A GARDENER.

VEGETABLE MARROWS, MARROW PEAS, AND APHIDES.

[THE following is in answer to "CONSTANT READER, *Croydon*," who complains that his Vegetable Marrows turn yellow and die off when 2 inches in length, and that his Marrow Peas are destroyed by aphides.]

I WOULD undertake to grow Marrow Peas and Vegetable Marrows to perfection at Croydon, as I know the place, and the texture of its soil. As to the myriads of aphides, for this exceptional season they must be left to the lady birds, which by the time this appears in print will most likely have devoured them all. The lady birds have done so here, in concert with another more gay and lively set, the horizontal-winged Syrphidæ, and most thankful am I for their appearance. I remember in the autumn, some few years ago, just such a flight of the black aphis—a neighbour told me he could scarcely see to drive along the road for them—and in this garden they settled more especially upon the Convolvuluses, and the Peach and Nectarine trees. I could now point out Peach and Nectarine trees in my neighbours' gardens, where the aphides were allowed to remain undisturbed, and which are still mere skeletons. I syringed my own trees, and the Convolvuluses, with house sewage heated to 120°; that settled the aphis, and saved my trees, and I think I can now say without boasting, that I can gather very fine fruit. Heated sewage is my remedy for aphis, red spider, and mildew. Its smell is unsavoury, and as something less objectionable, though effectual for destroying aphis, Pooley's tobacco powder could scarcely fail to be acceptable.

Now, with regard to the Marrow Peas not coming to perfection, and the Vegetable Marrows casting their fruit, these disappointments may be avoided by adopting the following system of cultivation:—Depth of soil is the first requisite for both crops; therefore, bastard or half-trench the ground. If for Peas, make a mark or line up the middle of the piece of ground; then at one end of the line to one side of the half of the ground, measure for a trench 1 yard wide, and cast out the soil opposite the end on the other half of the ground, taking out the soil one spit or spade deep, also the shovellings, or loose soil. With a Foster's patent fork break up the bottom spit or subsoil thoroughly, and allow it to remain at the bottom. Before we dig any further, wheel a part of the large heap of manure or compost, which in all well-regulated gardens is being constantly collected, and further enriched by the addition of house-slops, soapsuds, &c., and place as much of it as one can afford—a wheelbarrow load to a square yard may be considered quite sufficient—over as much of the ground as is likely to be trenched in one day. Spread evenly over the surface of the soil sufficient for a trench at a time; to spread at once the whole bulk over the surface would be to allow the sun and air to dry the manure, and to half-spoil it by driving off the ammonia. Attention should be paid to this point in applying all manures. Now shake enough of the roughest of the manure into the trench, measure another trench, and fork the top spit on to the bottom one previously broken up, and the shovellings on to that, taking care in so doing that the manure is well apportioned throughout the mass; fork up the bottom again, and so on till the work is completed to opposite the trench that was first made, where the top spit first thrown out is found quite ready to fill up the last trench. If fruit trees have been planted in the centre of garden quarters, do not dig within the drip of their branches, and as their roots are cut off up to that boundary, smooth the wounds with a knife; this will make the roots throw out young fibres and do good rather than harm. Always reserve the emptyings of the dry-earth-closets to be used on these special trenching occasions.

Having thoroughly prepared the ground, you may sow your Peas thinly, and anticipate grand results, especially if in dry weather thorough soakings of sewage from the house tank be occasionally given to the rows. There will not be the slightest chance of stunted growth, aphis, or mildew, where the above mode of proceeding is adopted.

Next with regard to the Vegetable Marrows. Of course, the proportion of ground for them would be very small in comparison to that required for the Peas. I shall suppose a warm corner sloping to the south, measuring, say 12 feet by 6 feet; or if in the open what matter? Trench and thoroughly manure the allotted space as for the Peas, and this alone will generally be satisfactory for their cultivation; but if in addition some or all of the following ingredients can be had (especially the rotted turf and charred refuse), and laid so as to form a slope 2 feet high at back, and 1 foot high in front, so as to catch the sunshine, doubtless greater results will be obtained. My last surfacing for the purpose was formed in the proportion of a cart-load of rotted turf, two bushels of charred and coarse wood ashes, three barrowloads of leaf mould, three barrowloads of thoroughly rotted horse manure, and half a dozen shovelsful of soot, the whole thoroughly mixed. We were surfeited with Vegetable Marrows. At the end of May, form two small hillocks at 2 feet from each end, and midway between the sides of the bed, as I shall call it, and place in the crown of each two young plants, either raised in a cool frame, or obtained in any other way; but if plants are not to be had, sow three or four seeds on the top of each hill. Shade the plants from the sun, and protect them from cold winds, and both for plants and seeds keep the ground sufficiently moistened with warm soft water, if it be necessary. If seed be sown, the young plants will come up in a few days. If three seedlings germinate in each hillock, thin them out to two, and by a little management and shading, their rough leaves will soon be of no further use, as young shoots will begin to start from the hearts of the plants. As soon as they can be taken hold of, tenderly pinch the hearts from out of two of the plants, one on each hill, and allow the others to grow without stopping. The plants will now be showing a length of bare stem which is not good for them, so place a little reserved soil round them, and press the stems gently outwards, and in so doing away from each other. This will not only encourage them to emit fresh rootlets, but will prevent their being too close together. Young roots will soon appear at the circumference of each mound; cover them with a few inches thick of the reserved soil, and so on till the bed is quite levelled.

As the runners of the unstopped plants advance, fix them to the soil with hooked pegs, or train them to a fence, if such is intended to be covered for ornament. The plants which were stopped will soon show a disposition to fruit upon the laterals, which spring from the bases of the leafstalks; with small hooked pegs fasten down the laterals on the top of the soil, and they will generally produce roots at their joints. The blossoms, male first, and then the female, will next claim notice, and the setting of the fruit would be rendered more certain if the female flowers were artificially fertilised. This is especially worthy of "CONSTANT READER'S" attention.

As the plants continue growing, do not let their shoots become too crowded. A young shoot will appear at the base of every leafstalk, and if all were allowed to grow they would weaken the plants at the expense of the fruit, which would to a large extent fall off prematurely. Two feet of space should be allowed between the main stems, and the superfluous laterals springing from these should be completely pinched out from the bases of their leaves to a foot distance from each other. Do not interfere with the large leaves, except to carefully pinch off a few now and then where too crowded for the free access of light and air to the soil; or, in the case of their acquiring a yellow tinge, when the plant's bearing powers are becoming exhausted. When a fruit is fairly set on a lateral, pinch off the head of the lateral, and in a few days the fruit will arrive at perfection, and the shoot will push again, and bear more, or, according to judgment, may be cut away. Thus the juices of the plant and the action of the leaves are devoted to fruit-producing, but the case is different with plants which are allowed to grow unchecked for ornament, and upon which very few fruit may be anticipated.

If dry weather prevail, water the plants thoroughly every evening with water which has been allowed to stand all day in a tub exposed to the sun, for they require a large amount of

moisture, and hard cold water stunts or kills them. Use soapsuds or sewage water sometimes, and let both be mixed with an equal quantity of clear water; but do not wet the leaves with the mixture more than is unavoidable. Water the soil between them equally and steadily from the long spout of the watering-pot, and not very near the places where the main stems start from the soil, as gangrene and canker very often follow that bad practice.

The above system may also be adopted for ridge or any other Cucumbers.—Upwards and Onwards.

ADULTERATION OF SEEDS BILL.

It is well known that a practice has been in use for many years past of mixing good seeds with seeds the vitality of which has been destroyed for the purpose of adulteration and profit. So general and extensive had this become, that even the seed trade itself regarded it as a scandal, and honourable men connected with the trade shrunk from a system which through custom and competition they were compelled in self-defence to follow. It mattered not how desirous a few individuals may have been to escape from this dishonourable course and to sell genuine seeds; it was practically impossible for them to do so, so long as others with whom they were brought into competition could undersell them with seeds which were to a large extent adulterated. The public, ignorant of these matters, naturally buy where they can do so cheapest, regardless of the maxim, that "the cheapest is not always the best," and acting on that principle of buying in the cheapest market, the public have themselves been active accessories in encouraging this system of "doctoring seeds." To such a pass had this practice reached, that some of the active members of the seed trade bestirred themselves with a determination to rid themselves of the reproach of systematically deceiving the public, and the result has been the passing of a bill in the last session of Parliament (32 and 33 Vic., chap. 112), rendering it penal after the 1st of May next, to infringe the clauses of the Act, which is as follows:—

AN ACT TO PREVENT THE ADULTERATION OF SEEDS.

Whereas the practice of adulterating seeds, in fraud of Her Majesty's subjects, and to the great detriment of agriculture, requires to be repressed by more effectual laws than those which are now in force for that purpose:

Be it therefore enacted by the Queen's most Excellent Majesty, by and with the advice and consent of the Lord Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows:—

1. This Act may be cited as "The Adulteration of Seeds Act, 1869."

2. In this Act—

The term "to kill seeds" means to destroy by artificial means the vitality or germinating power of such seeds:

The term "to dye seeds" means to give to seeds by any process of colouring, dyeing, sulphur-smoking, or other artificial means the appearance of seeds of another kind.

3. Every person who, with intent to defraud or to enable another person to defraud, does any of the following things—that is to say,

(1.) Kills or causes to be killed any seeds; or,

(2.) Dyes or causes to be dyed any seeds; or,

(3.) Sells or causes to be sold any killed or dyed seeds, shall be punished as follows—that is to say,

(1.) For the first offence he shall be liable to a penalty not exceeding £5:

(2.) For the second and any subsequent offence he shall be liable to pay a penalty not exceeding £50.

Moreover, in every case of a second or any subsequent offence against this Act, it shall be lawful for the court, besides inflicting upon the person guilty of such offence the punishment directed by this Act, to order the offender's name, occupation, place of abode, and place of business, and particulars of his punishment under this Act, to be published, at the expense of such offender, in such newspaper or newspapers, or in such other manner as the court may think fit to prescribe.

4. Any forfeiture or penalty under this Act may be recovered, enforced, and applied as follows:—

In England, before two justices of the peace in manner directed by the Act of the session of the eleventh and twelfth years of the reign of Her present Majesty, chapter 43, intituled "An Act to facilitate the performance of the duties of justices of the peace out of sessions within England and Wales with respect to summary convictions and orders," and any Act amending the same.

In Scotland, in manner directed by the Summary Procedure Act, 1864, and any Act amending the same, or by any police or other Act for the time being in force in any place, and providing for the recovery of forfeitures and penalties.

In Ireland, in manner directed by the Petty Sessions (Ireland) Act 1851, and any Act amending the same; and in Dublin by the Acts regulating the powers of justices of the peace, or of the police of Dublin metropolis.

Any jurisdiction by this section authorised to be exercised by two justices may be exercised by any of the following magistrates within their respective jurisdictions—that is to say,

As to England, by any metropolitan police magistrate sitting alone at a police court or other appointed place, or by the Lord Mayor or any alderman of the city of London, sitting alone or with others within the said city.

As to Scotland, by the sheriff or sheriff substitute, or by any police magistrate of a burgh.

As to Ireland, by any one or more divisional magistrate of police in the police district of Dublin, and elsewhere by one or more justice or justices of the peace in petty sessions.

The term "court" shall include the justices, magistrate, or other person or persons before whom proceedings may be had for the recovery of any forfeiture or penalty.

5. In any proceeding for any offence against this Act, it shall be sufficient to allege that the party accused did the act charged with intent to defraud or to enable some other person to defraud, without alleging an intent to defraud any particular person or an intent to enable any particular person to defraud any particular person; and on the trial of any such offence it shall not be necessary to prove an intent to defraud any particular person, or an intent to enable any particular person to defraud any particular person, but it shall be sufficient to prove that the party accused did the act charged with an intent to defraud, or with intent to enable some other person to defraud, or with the intent that any other person might be enabled to defraud.

6. In England, where the person who is convicted under this Act thinks himself aggrieved by the conviction, such person may appeal to the next court of general or quarter sessions, held not less than twelve days after the day of such conviction for the county or place where the conviction is had, in manner and upon the conditions in and upon which a person aggrieved by a summary conviction under the Act of the session of the twenty-fourth and twenty-fifth years of the reign of Her present Majesty, chapter 96, may appeal in pursuance of the 110th section of the said Act.

In Scotland and Ireland, in like cases as in England, an appeal shall lie in manner in that behalf provided by the law of Scotland and of Ireland respectively.

A summary conviction under this Act in England shall not be quashed for want of form, or be removed by certiorari; and a warrant of commitment on any such conviction shall not be held void by reason of any defect therein, if it is therein alleged that the person therein named has been convicted, and there is a good conviction to sustain the same.

7. Every complaint under this Act against any person in respect of selling or causing to be sold any killed or dyed seeds shall be commenced within twenty-one days from the time of the commission of the offence complained of.

8. Whenever any complaint is preferred against any person under this Act, and the court upon the hearing thereof determines that it is not *bonâ fide* made upon reasonable and probable cause, it shall be lawful for the court in its discretion to direct and order that the prosecutor or other person by whom or at whose instance such complaint has been preferred, shall pay unto the accused person the just and reasonable costs, charges, and expenses, to be settled by the court, of such accused person and his witnesses, occasioned by or consequent upon the preferring of such complaint; and upon nonpayment of such costs, charges, and expenses within fourteen days after the date of such direction and order, it shall be lawful for the court to enforce payment of the same in the same manner as if such costs were a penalty incurred by the person liable to pay the same.

9. Nothing in this Act contained shall prejudice or affect the power of proceeding by indictment or libel in respect of any offence herein provided for, nor shall any proceeding, conviction, or judgment to be had or taken under the provisions hereof against any person prevent, lessen, or impeach any remedy by civil process at law or in equity which any party aggrieved by any offence against this Act might have had if this Act had not been passed.

10. This Act shall commence and take effect on the 1st day of May, 1870.

A bulky blue book has been published with the whole of the evidence taken before a committee of the House of Commons on the subject;* but as this alludes merely to Clover and other agricultural seeds, we confine our extract to that part which refers more immediately to garden seeds. The following is the evidence of Mr. Burnell, of Waite, Burnell, and Co., and next week we shall give that of Mr. D. Nash, of Minier, Nash, & Nash.

Evidence of Mr. John Thompson Burnell.

Chairman.—You are a member of the firm of Waite, Burnell, Haggins, & Company, of Southwark Street?—Yes.

* The members of the Committee were—Mr. W. Earle Welby (Chairman), Mr. Henry Brand, Sir Michael Hicks Beach, Bart, Mr. Shaw Lefevre, Mr. Collins, Mr. Cross, Mr. Norwood, Mr. M'Lagan, Sir Henry Selwin-Ibbetson, Bart., Mr. Morrison, Mr. Cogan, Mr. Backhouse, Mr. O'Neill, Dr. Playfair, and Mr. Pelt.

Are you the senior partner in that firm?—I am the active partner in the firm.

May I ask how long you have been in the business?—Our firm has been in business about five years. I have been in business about twenty years: fifteen years, with my step-father, the late Mr. Waite, and five years as the active partner and manager of the present firm.

You do, I think a very large trade?—Yes.

Probably one of the largest in London?—About one of the largest.

Is your trade confined to the United Kingdom?—No; our trade is in England, Ireland, Scotland, Wales, America, and in various parts of the world.

I think, also, that your business is not confined to any one description of seeds?—We are not largely engaged in the Clover seed trade. I do not profess to be an authority on the Clover seed; our trade is principally confined to Turnip seed, Mangold Wurtzel, and garden seeds generally; Clover seed, Flax seed, bird seed, and seeds of those kinds, we do little or nothing in.

Have you for some time past set your face against these practices of adulteration?—As far as I have been able to do so, I have.

Are you able generally to confirm what Mr. Sharpe and Mr. Kennedy have told us as to the practice of killing and colouring seeds?—Generally, I think that I can confirm all that was said by these gentlemen.

Particularly as far as regards Turnip seed?—Yes.

And that that has been the practice for many years past?—It has.

In fact, as long as you have been acquainted with the trade?—Yes.

Should you say, generally, that the large wholesale houses are anxious to get rid of the practice, but have it forced upon them by the competition that they have been subjected to?—I should say that they are very anxious to get rid of it.

I think that you are one of the gentlemen who signed a memorial on the 22nd of June to the President of the Board of Trade?—I did sign it with great reluctance.

Will you just look at that, and see if it is a correct copy (*handing a paper to the Witness*)?—I should say that this is a copy of it; I was the last to sign it; and my reason for signing it was, simply, that there should be unanimity among the Loudon seedsmen. Although I signed it, I certainly had a strong opinion that the memorial, so far as the bill is concerned, would be of very little good indeed.

Will you read that memorial?—"To the Right Honourable John Bright, M.P. Adulteration of Seeds Bill. London, 22nd June, 1869. Sir,—We, the undersigned seed merchants, beg respectfully to suggest that from the difficulty of proof that genuine seeds have been mixed with killed or dyed seeds, and that deficiency of growth may arise from unfavourable seasons for maturing seeds, bad harvests, or heating in the stack. It would simplify the bill and render it much more effective by expunging the clauses 4 and 5; this would afford protection to the merchant against being charged by any unprincipled party 'who could not pay his account, or the market had gone against him,' with having sold adulterated seed. That in clause 7, for whosoever shall be convicted 'of any offence against this Act,' substitute 'of killing or dyeing seed, or knowingly shall import killed or dyed seed.' Thus altered the clause would read, 'Whosoever shall be convicted of killing or dyeing seed, or knowingly shall import killed or dyed seed, shall, for every such offence,' &c. This would, in the opinion of the undersigned, effectually put an end to the manufacture of killed and dyed seed, as no party would like to subject himself to being informed against by any person who is or may have been in his employ. We have the honour to remain, your very obedient servants, Minier, Nash, & Nash, 60, Strand, London; Rutley & Silverlock, 412, Strand; Fraser, Goad, and Ratford, 82, Bishopsgate Street Within; James Carter & Co., 237, and 238, High Holborn; Hurst & Son, 6, Leadenhall Street; Charlwood & Cummins, 14, Tavistock Row, Covent Garden; Henry Clarke & Sons, 39, King Street, Covent Garden; Robert Cooper, 152, Fleet Street; Beck, Henderson, & Child, 221, and 222, Upper Thames Street; Waite, Burnell, & Co., Southwark Street, S.E.; Nutting and Sons, 60, Barbican, E.C." Will you allow me to say that Messrs. Nutting & Son were not present, but they signed the memorial after the meeting?

Are you still of the same opinion as is expressed in that memorial, as to the difficulty of detecting killed seeds?—No, I am of a contrary opinion.

In fact, then, you agree rather with the evidence that has been given to this Committee that the presence of killed seed can be detected with great facility and certainty?—Yes.

And do you still hold the opinions expressed in that memorial, that the bill would, with the clauses 4 and 5 expunged, be effective for all the purposes for which it is desired?—I did not agree with that memorial at all. I signed it merely that there should be unanimity amongst the London seedsmen; but I do not agree that the omission of those clauses would be effective.

If the bill was confined to the third clause simply, the killing and dyeing of the seed, it would virtually result merely in a transfer of the scene of adulteration?—Yes, it would amount to this, that once get killed seed by any means, and let it pass through two or three dealers' hands, it would then come into the hands of the mixer, the person who would mix the seed, and I take it that you could not then convict that man for selling mixed seeds.

With regard to including dead seed in the provisions of the bill, did you hear the evidence that was given by Mr. Murray?—Yes; but I could not follow it exactly.

Perhaps you have not had an opportunity of seeing that evidence since?—I have not.

To put it shortly, are you of opinion that it would be possible to compel the seller to give a guarantee that his seed should germinate a certain per-centage, and to make him liable to a penalty if it did not come up to that per-centage?—I think that it would be utterly impossible, because some seeds in the autumn may produce a good growth, say 90 per cent., or 80 per cent., or any given per-centage, and in the spring the same seeds very likely would fall off in growth; so that if we were to give a guarantee with each parcel, we should have to try our seeds every week, and even then one could not be quite sure.

In fact, you would say that that was not the suggestion of a practical man?—It is quite impracticable.

We have had a great deal of evidence about Turnip seed and Clover seed; but I should like to ask you whether there are any other vegetable seeds in which this practice of adulteration exists to any extent?—Yes; Cabbage seed, Broccoli, Cauliflower, Kale, and all round seeds, the killed seeds of which could be easily detected, as in Turnip seeds.

And do you think that the injury to the consumer by the adulteration of them is as large in proportion to the extent of the seed used as it is in the branches of which we have heard so much?—I should say more so, because take, for instance, Cabbage and Cauliflower; the seeds are sown in beds for plants, and all those plants are wanted, either for transplanting where they are to become vegetables, or to sell as plants, and, of course, the fewer the seeds which grew the fewer the plants; consequently, the loss to the gardener would be greater in proportion than in the case of Turnip seed.

You mean that in the case of a field sown with Turnip seed, if 70 or 80 per cent. comes up, it is probably sufficient for the farmer for practical purposes?—Yes.

But that in the case of a market gardener he requires 100 per cent.? He requires all the plants he can get from the seed.

Mangold Wurtzel is an important seed in agriculture; is that adulterated within your knowledge?—It is adulterated.

By what means?—Common kinds, of Sugar Beet, for instance, may be killed and mixed with Mangold seeds, or a bad stock of Mangold Wurtzel may be killed and mixed with a better kind. I think that is about all I know of it.

Should you say that Mangold Wurtzel seed is regularly adulterated every year, or does it vary according to the season?—It would vary according to the season, because some Mangold Wurtzel in a bad autumn is of a very inferior quality indeed, and, in fact, we have known Mangold Wurtzel seed in some seasons to be of such quality as to be scarcely saleable by a merchant, and then one or two-year-old seed would be preferable.

An honourable member spoke the other day about Onion seed being killed occasionally; can you tell me whether that can be discovered?—It can.

By the same test?—No; the only means I think that we should have would be by tasting the flavour of the seed, besides of course testing it in soil; the flavour of new Onion seed is very strong indeed. The killed Onion seed has not the Onion seed flavour at all, but a burnt flavour.

As to the flower seeds, seeds used in flower gardens, is there much killing in regard to them?—Not much.

And you would not consider it of the same importance to include them in the bill?—I should not; I should consider them of very little importance.

And perhaps the practice will be not so easily detected, even where it is carried on?—Well, I should say it would scarcely be detected; it is of such little moment that I do not think much attention has been paid to the adulteration of flower seeds.

Can you recall any other sorts of seeds besides those which you have mentioned, in which adulteration is carried on to any extent?—To a limited extent Radish may be adulterated; but it is easily detected, even though it is adulterated to a very small extent.

The list you have given me comprises, virtually, all the seeds in which adulteration is carried on extensively?—Yes.

Mr. Shaw-Lefevre.—You come here, principally, with the purpose of withdrawing your name from this memorial, which has been presented to the Board of Trade, against certain portions of the bill?—I am not aware of that.

I understood you to say that you no longer agree with that memorial?—Decidedly so.

You signed your name to it on the 22nd of June, not agreeing with the terms of it?—Yes. Allow me to say that there were two other firms who likewise signed that memorial, but who protested against it as being weak and ineffectual; those firms are Hurst & Son, and Carter and Company.

At all events you yourself signed it without agreeing with its terms?—Yes.

And you now come for the purpose of saying that you do not agree with its terms, and that you are in favour of the bill as it stands?—I am in favour of the bill as it stands.

You stated that your reason for signing the memorial was that there might be a unanimity in the trade?—Yes.

You signed one of the last with that view?—Yes.

Then you had found that at that time there was something like

unanimity in the trade?—I was pleased to find there was, and I did not wish to stand alone.

At that time there was something like a unanimous feeling on the part of the trade against certain clauses of the bill, is that so?—No, I do not know that there was.

What I understood you to say was this; that you signed the memorial because you wished there to be unanimity on the part of the trade?—Yes.

But you did not agree with it?—I did not.

I ask you whether at that time you had found that there was something like unanimity?—There was not a very strong unanimity, because, as I have already told you, there were two firms who protested against it, although they did sign it, and the majority of the trade wanted a bill of some kind, and wanted it to be as effectual as possible.

But they did not wish those clauses which imposed penalties very specially in the event of their having killed seed in their possession?—Just so.

They thought that would be an interference with their trade?—Yes.

That it might render them liable to prosecution from farmers, who thought that the seeds had been improperly doctored, when they had not?—Yes; I presume that was the feeling.

You said that you had done your best to set your face against adulteration?—Yes.

Have you sold any samples of adulterated seed?—Oh, yes.

Then you have not gone against it to the extent of abstaining yourself altogether?—Certainly not; I could not afford to do it.

What measures did you take?—I have instructed my travellers, where practicable to sell net genuine seeds to do so; and I have taken the earliest opportunity that presented itself since I have been master of my own actions to combine to put it down if possible.

But for many years you continued to sell these adulterated samples? For five years. I have been master of my own actions, and for fifteen years I was with my step father, Mr. Waite.

Since you have been master of your own actions, have you sold any adulterated seeds of this kind?—I have.

Mr. Cross.—You say you have instructed your travellers to sell net seeds, if possible?—Yes.

Were they to tell the customers that you have two kinds of seeds, one adulterated and one not?—Where the question of net seed was named, then it would be understood that if they bought net seed they would have net seed, but that if they did not buy net seed they would have seed used according to the custom of the trade.

Are the customers that you are speaking of those retail shopkeepers? Some of them.

Any farmers?—No.

No actual consumers of the seeds?—No; what trade we do direct with the consumer is all done with net genuine seed.

You never have ventured to sell adulterated seed direct to the consumer?—Well, I should not do that, because competition does not demand it.

I say have you ever ventured to sell adulterated seed to the consumer?—I should say not.

Do all the country dealers know perfectly well that the seeds they buy of you are adulterated?—A great many of them would; I had one case only last season: my traveller had booked a very large order, amounting probably to £1200 or £1300, and the order was submitted to me by my traveller to decline or accept at the prices. There were some items of Turnip seed, at very low prices indeed, so low, in fact, that there was no profit attached to them; but the order, taken as a whole, I could execute at the prices. On these Turnip seeds I wished to get an advance in the price of 1s. a-bushel, merely to pay common interest of money; to my surprise, I heard from the people that as I had not accepted the order as it stood, they were very sorry, but they had given it to somebody else. I have subsequently heard that that order was given to another firm, because that firm agreed to reduce the seed to a growth of something about 60 per cent. So that it was a question of growth that lost me the order.

It was not that you stuck up for selling net seed that lost you the order?—I did not offer net seed; the seed offered by my traveller was seed understood to grow about 70 to 75 per cent.

How much of the profit of the adulteration goes into the seed merchant's pocket?—Very little; I should say nothing.

Do you mean that all the profit of the adulteration goes into the consumer's pocket?—I should say that there is no profit attached to it, either to the merchant or the retailer, or the consumer. The reduction in the quality has brought about such an amount of competition that the consumer must suffer; he must be the only person, I should say, who would suffer.

Dr. Playfair.—You spoke of the test of a certain per-centage growing not being a good one for seed; how old was the seed you spoke of when you said that a test made in the autumn might be a very different test if tried in the spring?—I only gave that as an instance; I did not apply it to any special kind of seed.

Take the case of a seed a year old, would there be any great difference between a young seed in the autumn and that same seed in the spring?—We will take the case of a wet autumn. The seed would not be in so good a condition as in a fine autumn. That seed would be longer about in the harvest and maturing, and probably would be of a weak growth when it came in. The chances are that that seed would fall off in its vitality in the spring of the year.

Considerably?—Sometimes considerably.

Even the seed of the last autumn?—Yes, even the seed of the last autumn; that applies, of course, to a bad harvest.

And the more rapidly, I suppose, the older the seed was, if you had a three-years-old seed for instance?—I have known a three-years-old seed to grow as well almost the third year as when harvested, if it is good seed.

You are not afraid, then, of the three-years-old seed falling off much more rapidly in the test between the autumn and the spring?—In some cases it might, but thoroughly good harvest seeds of some kinds would do well for two or three years and even longer sometimes.

Then it would be the exceptional cases where there was such a speedy falling off as you spoke of?—It would be the effect of a bad harvest, or of a bad harvesting.

Mr. M'Lagan.—You said it might arise from bad harvesting or bad crops, but might it not arise more from bad keeping than anything else?—It might arise from bad keeping.

In many cases it does arise from bad keeping, does it not?—Well not in the hands of a merchant who has the facilities for keeping seeds, who has good stores.

Have you been present during the few days we have been taking evidence?—I have, every day.

The question has been frequently put as to what time should be allowed for information to be brought against the merchant for selling adulterated seed, now what time would you allow?—That is a very important question, but so far as it is one affecting myself as a merchant it is not so important as it is considered as affecting the commission agents, the factors, where short credit is taken; and I think that more important evidence might be given on that point than I should be able to give. So far as I am concerned, I should say that my customers would be able to test their seeds and should make complaints, if they have any cause to make any complaints, within twenty-one days. I should consider that that would be allowing them ample time.

The time that has been said, generally, is thirty days or a month?—I think you will find that that would be a serious matter as regards the factors.

Even a month?—Yes.

Take twenty-one days; does it matter at all to the factor, or the wholesale merchant, if the time is to be twenty-one days, whether there is any deterioration in the growing quality of the seed from autumn till spring; there surely will be no great difference, at all events, in the germinating power of the seed in twenty-one days?—I should say none.

Therefore it is of little consequence whether the seed does become deteriorated in its germinating power from autumn to spring? So far as adulteration is concerned, I should say that it is of very little importance.

But so far as mixing with old seed is concerned?—I do not exactly understand the question in that form.

I understood you to say to the honourable Member for the University of Edinburgh that seeds often lose in their germinating power from autumn to spring?—Yes.

Unmixed seed I understood you to mean?—Yes, unmixed seed; we will take an instance of that kind. If we had seed of a weak growth in the autumn we should make allowances for its going off in the spring; at least I should.

I want to know will it make any difference if you limit the time for laying an information to three weeks, whether the seed has deteriorated in its growing quality from autumn to spring?—I should say not.

And therefore do you think that there would be any difficulty in you guaranteeing to the purchaser a proportion of germinating power in the seed which you may sell?—What proportion would you wish guaranteed?

I merely ask a general question. You said it would be impossible to do it, I think, in the answer you gave just now?—Yes; that is, taking the extreme growth, which probably might be demanded of us. I would guarantee seed with safety to grow 50 per cent., but if a seedsman demanded of me whether that seed should grow 90 or 95 per cent., I should not venture to give a guarantee as to growth.

You are quite prepared, however, to guarantee a certain proportion of germinating power in the seed?—If guarantees were introduced in that way into the seed trade, I have no hesitation in saying that there would be very few seedsmen.

But I understood you to say that you lost a particular transaction from another merchant coming in and selling seed which he guaranteed?—I do not know that he guaranteed it. It would be merely a representation; there would be an understanding.

But I understand that you gentlemen are all men of honour, and an understanding is quite equal to a guarantee?—Decidedly.

He guaranteed it in that case to have a germinating power of 60 per cent.?—He so represented.

Therefore there is, at the present time, an understanding that the seed you sell has a certain germinating power?—Yes, it is tacitly understood in the trade.

And that is quite equivalent to a guarantee amongst the merchants themselves?—I do not know that it is equivalent to a guarantee.

You could not sue upon it, but as an honourable transaction it would be?—As an honourable transaction it would be.

If it is a point of honour, why not make it a point of law?—I am not competent to answer that question.

You deal extensively in Mangold Wurtzel, do not you?—Yes.

And I think you stated that it is considerably adulterated also?—It

is not adulterated, so far as my own experience is concerned, to the extent that other seeds are.

It is, however, mixed sometimes with the seed of the Sugar Beet?—Yes, sometimes.

And is that seed killed?—Yes.

Can you easily distinguish Mangold Wurtzel adulterated with Beetroot?—You cannot.

Not even an expert?—No, I would not profess to judge Mangold Wurtzel.

I have a sample here, and I was going to ask if you could tell the difference?—No.

What is the difference in the price of Beet seed and Mangold Wurtzel seed?—It all depends upon the season; sometimes we have Mangold Wurtzel seed as cheap as Beet seed.

Take the average?—Well, I suppose £20 a-ton for Sugar Beet, and for Mangold Wurtzel £30 to £33.

Therefore there is a difference of about 50 per cent. in the price?—About that.

And you say that the seed merchant who mixes these two kinds of seeds derives no profit from that mixture?—Well, the profit I should say is very little on account of competition: there is as much profit out of genuine seed as there is out of adulterated seed, generally speaking.

That is to say if all the merchants sold genuine seed there would be as much profit as if they all sold adulterated seed?—Yes.

Therefore the only loser in this trade of mixing is the poor farmer? I should say he is the loser, from my own observation in the matter.

But he is a loser?—I should say so.

It has been given in evidence that he is not, in as far as he gets his seeds cheaper; what have you to say to that?—That is another matter altogether; so far as he gets his seed cheaper he may not be a loser; but the question is whether adulterated seeds are as cheap as good seeds.

If you look to the ultimate produce of the crops there is no doubt that he is a very great loser by buying adulterated instead of unadulterated seed?—Yes, in that light he is.

Mr. Brand.—I understand you to say that you have been about twenty years in the seed trade?—Yes.

Has that practice of adulteration increased within your experience?—I should say it has.

Has it extended to different classes of seeds?—Yes, all classes.

That is to say, that seed which, when you began business, were not adulterated, are adulterated now?—No, I should say that all kinds of seeds that were adulterated when I first had a knowledge of the trade are still adulterated, and I do not know that they have increased in sorts, though they may have done so; but I should say that in general the practice has increased.

And the demand for these seeds, especially Turnip and Mangold, and Clover, has increased very largely in your recollection?—Yes, very largely; more particularly in Ireland.

Chairman.—I think you said that you considered that the Bill would be operative in the form, or nearly in the form, in which it now stands?—I think so; at least, I have very little doubt about it.

Do you think that the seedsmen themselves would take any steps to assist its operation by forming themselves into an association?—There is no doubt that there will be an association of some kind formed.

With the object of assisting the operation of the Bill?—Yes.

Under which the seedsmen would constitute themselves, as members of their own bodies, inspectors to report cases to the trade, and lay information where they discovered practices of adulteration to be carried on?—Yes.

Now I should just like to ask you what you think would be the effect of all this inquiry, supposing that this Bill was not passed into law; do you think the publicity given to the matter will have the effect of discouraging the practice, or, on the contrary, do you think that the adulteration would increase from the greater knowledge of the practice that would be obtained?—While it is fresh in the mind of the public it may probably deter the practice to a limited extent; but we shall soon forget it again, and more particularly when we have a scarcity of seeds. If Parliament does not interfere with it, I believe that in a very short time it will be even more on the increase; I believe that it will be carried on by inexperienced persons, and consequently a great deal more injury will be done in the use of the killed seeds than under the present system, as it is now carried on by experienced persons.

You have said that you think the number of sorts of seeds to which the practice of adulteration is applied has not increased, do you think that the number of districts in which it prevails has increased?—Well, I cannot exactly answer that question. I think that the head-quarters for colouring and for killing seeds would be in London. There may be other places which have not come to my knowledge; in fact, I have no doubt that there are other places.

But, speaking generally, you think that the practice is rather on the increase than on the decrease?—I should say so.

Mr. Shaw-Lefevre.—Do you test your seeds before sending them out?—As soon as we receive them from our growers we test them.

So that you know their germinating power before you send them out?—Yes, that is, we test them when they come in in the autumn, and if there is a weakness of growth, we note it. In fact, we note all the growths, but we take special notice of a weak growth.

You agree, then, with Mr. Sharpe and other witnesses, that in adulterating samples with killed seeds, the practice has been to adulterate them down to a certain per-centage of germinating power?—I do not quite agree with what has been said about that, because I believe that generally the seeds are made up on an average; that is, in Turnip seed, three of the genuine seeds to one killed seed.

But what has been your own practice in mixing killed seeds with genuine seeds?—Upon that rule.

Then your endeavour has been to reduce the germinating power of the sample to 75 per cent., or about that?—Well, it comes below that; about 70 per cent., I should say.

But supposing that in testing your seed you have found it to be not up to the average, you have mixed somewhat less of killed seed?—When it is a bad growth, much below an average, then of course we should not reduce it to such an extent.

Your endeavour has been to keep the standard at the same level year by year?—Sometimes we deviate from the rule.

As a general rule, that has been your endeavour?—As a general rule it has.

What do you consider that standard to be; between 70 and 75 per cent.?—About 70 per cent.; to get 75 per cent. when the proportion is three and one, every genuine seed must grow.

Dr. Playfair.—Do you agree with Mr. Sharpe in desiring that there shall not be included in clause 3 any prohibition against oiling seeds to improve their appearance?—I think that oiling seeds being part of the preparation for cleaning seeds, would be beneficial to the seeds.

What makes you think so?—From my own experience; for instance, it cleans them from dust and mites (a very small insect). It would congeal the seed sometimes, unless we had a process of cleaning the seed from those little insects, to say nothing of dust; I think it would be wrong, therefore, to prohibit oiling the seeds.

Did you ever try any experiment as to the germinating power of oiled seeds and seeds not so treated?—Oiling seeds would not affect the growth of them.

Have you tried any positive experiments on them?—I have general experience; but I have not tried positive experiments.

You do not know whether it affects their germinating power?—I do not hesitate to say that it does not affect the growth or the germinating power.

And therefore you would not wish it included in this clause?—No; I think it would be wrong to include it, and to consider it as an adulteration.

Mr. M'Lagan.—Though it may not destroy the germinating power of the seed, would it not retard the germinating power?—No, not at all.

Will the oil on the outside of the husk of the seed not prevent that seed being properly moistened with water before it can germinate?—I should say not at all.

We had in evidence that the seeds with which Turnip seed is adulterated are sold as warranted not to grow; are you aware whether that killed Beetroot seed, which you have alluded to as used to adulterate Mangold Wurtzel, is sometimes sold, too, as warranted not to grow?—I should say that it is sold with the understanding that it will not grow.

But not with a warrant not to grow?—No; but it is generally understood it will not.

Are you aware of the lowest price at which that Beetroot is sometimes sold?—I do not know; I have had so very little to do with that.

I thought you dealt extensively in Mangold Wurtzel?—Yes; but I have not had much to do with Beetroot; Mangold Wurtzel is not adulterated to the extent that other seeds are.

Have you known Mangold Wurtzel seed to sell for £120 a-ton?—Yes.

Of course, in that year there would be extensive mixing with Beetroot at £10 a-ton?—Yes.

Would there not be a great profit in that case to the salesman?—I daresay there would be in many transactions.

And a great loss to the farmer?—Yes.

Are there any other seeds with which Turnip seeds are adulterated, excepting Rubsen seed?—None except Rubsen seed, and the seed sometimes called Indian Rape; it is very much like Rubsen seed. And then there is the black Rape for Swede Turnip.

There is a small seed very often found as a weed amongst our crops, in Scotland and Ireland, is that ever riddled out?—I presume you are alluding to Charlock seed. Any merchant knowing his business would not use that, because it is so utterly distinct from anything else.

Though an expert might distinguish it, do you think a farmer could distinguish it?—Probably he might not; he would if he had once given himself the trouble to think about it.

PREVENTING AND DESTROYING MILDEW.

Feeling myself to be largely indebted to "the Journal," for the varied information which I have from time to time gathered from its most instructive columns, and regarding it, as I do, in the light of the most efficient aid accessible to amateurs like myself, who in all their numerous difficulties turn to it for counsel and assistance, I venture to offer a few observations for the consideration of such of your readers as have suffered from this most insidious enemy, and unfortunately their name is legion.

I have been in the habit of keeping pot Roses in an orchard house, and somehow, notwithstanding plenty of air being regularly admitted, my Roses were frequently and periodically

attacked by mildew in a most aggravated form. I tried Mr. Radclyffe's remedy of blue vitriol and water, but with very little effect. I afterwards used regularly a dredging of flowers of sulphur, and by this means I could cure it; but the cure was slow, and therefore unsatisfactory. I was one day in the orchard house with my medical man, and he, noticing the Roses covered with their yellow sprinkling, inquired the cause. Upon being informed, he proceeded to enlarge upon the particular effect produced upon vegetation by flowers of sulphur, and in checking the mildew, and at the same time went on to observe, that if the heated fumes of the flowers of sulphur, accompanied with considerable moisture, could be brought directly to bear upon the plants, the effect would be much more speedy and complete than that produced by the mere contact of the sulphur when sprinkled over the foliage.

I took the hint, and proceeded to endeavour to improve upon it, and the result has been most satisfactory. I can now cure the very worst cases of mildew, or, at all events, effectually check them in about two days.

The *modus operandi* is as follows:—Place the plants on a common greenhouse stage in a small greenhouse or summer house, or any other place where the fumes of the sulphur will be well confined. Under the stage place a large flat milk dish or other vessel, and having heated three or four common bricks nearly red hot (firebricks would be better, as the common ones are rather apt to fly with the heat), place them in the bottom of the vessel; then fill it up nearly even with the upper surface of the bricks with boiling water, and on the bricks lay flowers of sulphur; scatter some over the surface of the hot water, and renew the sprinkling from time to time, as long as the bricks and water keep sufficiently hot. The fumes pass among the foliage of the plants ranged in tiers on the stage above. The following day syringe the plants well with cold water, and you will have no more trouble with them for some time.—A. Dumbell, *Ramsey, Isle of Man.*

[We have seen this season the mildew on Roses effectually cured at Sawbridgeworth, by the application of soot dusted over the plants in pots. This not only destroys the mildew, but improves the colour of the Roses.—Eds.]

HARDY CLIMBERS AND OTHER PLANTS FOR WALLS.—No. 2.

It may be well to distinguish between the climbing and other plants suitable for covering walls. "Climbers," states the "Cottage Gardeners' Dictionary," "are plants which attach themselves to supporters by their natural appendages, as by their tendrils, by their hooks, or by other modes of attachment." This will be sufficient to distinguish them from other plants.

CLIMBERS.

Akebia quinata.—Evergreen twiner. Flowers lilac pink, in spring and early in summer. Propagated by division of the root, and cuttings of the half-ripened shoots in sand on a gentle hotbed. It requires a south wall, and peat and sandy loam.

Ampelopsis hederacea (Virginian Creeper).—The most vigorous of all climbers, succeeding on any aspect, and excellent for covering trellises and rustic work, thriving where many other climbers will not do so, especially on a north aspect. The flowers are inconspicuous, but the foliage is a full compensation for any deficiency of flowering. It gives a close mantling to any building or object, the leaves dying-off a bright purplish red. It will grow in any kind of soil, but succeeds best when encouraged with good, rich, well-stirred loam. It is deciduous, and increased by layers and cuttings of the ripened shoots. Being of vigorous growth it is very suitable for covering high walls and buildings with unfavourable aspects. *A. quinquefolia* does not differ from A. hederacea.

A. japonica.—A new Virginian Creeper, of a compact shrubby habit, the leaves being broad, ovate-oblong, and in autumn assuming a bright red tint, in this respect surpassing A. hederacea. It will doubtless prove as hardy as the preceding.

A. Veitchii.—Foliage smaller than that of A. hederacea; the leaves are sometimes entire and occasionally thrice-divided, and are very close and dense; colour green, shaded with purple. Very fine for walls with north aspects, and rustic work of all kinds, being very hardy; and on account of its peculiar-coloured foliage and young shoots, which are quite purple, it is worthy of greater attention than it has yet received. It is the best climber for planting against walls where nailing cannot be practised, as it needs no training, but clings to any building with the greatest tenacity. The leaves turn red in autumn before falling.

Aristolochia Sipho.—Foliage bold, not unlike Rægner's Ivy; flowers yellow and brown, produced in July. It is suitable for walls with east or west aspects, and for verandahs and summer-houses, but in warm situations only. Sandy loam is the most suitable soil. Deciduous. Propagated by division of the roots or layers, either in spring or autumn. 30 feet.

Atragene americana.—Deciduous, succeeding in any common soil. Fine for rustic work. Flowers purple, in July. 15 feet. A. austriaca.—Flowers brown and yellow. July. 8 to 10 feet. A. sibirica.—Whitish-yellow flowers. July. 12 feet. Increased by seeds sown in sandy soil in a frame, the seedlings being pricked off when large enough, and gradually hardened off; also by layers in autumn, or by cuttings under a hand-glass or in gentle heat, either in spring or summer.

Berberidopsis corallina.—Evergreen, not exactly a climber, being only sub-scandent. Flowers fine deep red, in clusters of two or three, on long pedicels. It is but little known, and appears very hardy.

Bignonia grandiflora.—Free-growing climber with orange-red flowers produced in summer, but it requires a south wall. The foliage is bold and handsome. As the flowers are produced on the short shoots which proceed from the wood of the previous year, care must be taken to have the latter well ripened by thorough exposure, keeping the shoots moderately thin and rather closely nailed or tied-up.

Bignonia radicans.—Flowers orange, in July. Vigorous, and similar to the preceding, but not so good, though it is hardier. There is a better-coloured variety called superba. This and the preceding are deciduous, and only suitable for trellises against walls, verandahs, and other warm situations. They are increased by cuttings of the shoots, and by pieces of the roots in gentle heat.

Bignonia capreolata.—Flowers red. In warm situations, against a south or west wall, it is very ornamental.

The Bignonias succeed best in a compost of equal parts of peat and loam. Protection should be given this in severe weather.

Billardiera longiflora.—Red flowers in July. B. mutabilis.—Red, August. B. scandens.—Purple, August. All evergreens requiring a south aspect, and peat and loam compost. Propagation by seeds sown in a hotbed in spring, and from cuttings in June in a hotbed, covering them with a bell-glass.

Caprifolium flavum.—Yellow. 10 feet. Deciduous. Trellises in warm situations. C. Douglasii.—Orange. 20 feet. Deciduous. Pillars, arbours, and rustic work. C. Periclymenum.—Yellow; 20 feet; the Woodbine so fine for covering rustic trellises, arbours, or trunks of trees. June. It and the varieties are deciduous. Periclymenum belgicum, or Dutch, larger and earlier-flowering, June, 20 feet; Periclymenum serotinum (late Dutch), yellow and red, 20 feet, June; Periclymenum quercifolium, yellow and red flowers, June. There is a variegated variety of this. Except the first all are fine for pillars, arches, and covering all kinds of rustic work, but they should have open situations, for though they may grow, they do not flower freely on north aspects or in the shade. Against walls they are smothered with aphis.

C. sempervirens.—Evergreen, also its varieties Brownii, floribunda, and Youngii, all with scarlet flowers. Fine for trellises, verandahs, and poles, the flowers being long and trumpet-shaped. Rather light soil is most suitable.

The Caprifoliums are increased by cuttings of the ripened shoots in autumn, in a shady border, covering them with a hand-glass or inserting them under a frame. Layering in autumn when the leaves are falling is the most certain method of propagation.

Celastrus scandens.—Deciduous. Flowers yellow, in May or June. 15 feet. Seeds in a hotbed in spring.

Clematises.—Cærulea grandiflora, pale azure blue, 10 feet; flamula, white, 20 feet, sweet-scented; florida, white, 10 feet; and its double variety, white, tinged with green; bicolor (Sieboldi), straw, puce and green centre; Fortunei, large, double, white; hybrida splendida, deep violet, stamens green; Jackmanni, violet purple, centre veined, stamens light green; lanuginosa, lavender, large; lanuginosa candida, large, white; lanuginosa pallida, pale lavender; montana, white, stamens green; montana grandiflora, larger than the species, flowers white; Helena, large, semi-double, white; Louisa, white, with purple-tipped stamens; Sophia, mauve, centre of petals straw-coloured, stamens tipped with chocolate; there is a double variety of this similar in colour; rubro-violacea, maroon, shaded reddish violet, stamens pale green; Standishii, deep bluish violet; Viticella, purplish violet; and its variety multiplex with double flowers of the same colour; Viticella atrorubens, deep purplish red; venosa, reddish purple, veined crimson, light centre, stamens chocolate; Vitalba, or Traveller's Joy, white. This is the most hardy, and quickly covers any surface.

All the Clematises are fast-growing and free-blooming, indispensable for covering trellises, walls, rustic, and all kinds of ornamental wirework. Their rich and varied-coloured flowers, many of them large and sweet-scented, render them particularly desirable. All are deciduous. Propagation is effected by cuttings of the firm side shoots in summer, inserted in sand under a hand-glass or frame, keeping them shaded and close; or by layers in September. A light, rich, well-drained soil is most suitable.

Hedera algeriensis, fine large leaves, requires a warm situation; algeriensis variegata, a fine silver-variegated Ivy; canariensis (Irish

Ivy), free, close-growing, large handsome foliage; canariensis variegata, slightly variegated, free growth, close habit; canariensis aureomaculata, golden variegation in blotches, not very constant; canariensis latifolia maculata (marmorata), gold-clouded, but often green; Helix (English Ivy), fine, large, green leaves; Helix aureo-maculata, golden variegation, but not constant; Helix chrysocarpa, yellow-berried; Helix variegata (foliis argenteis), silver variegation, and very fine for buildings required to appear antique; digitata, fine for rustic work of all kinds; taurica, small, much-divided leaves, neat and distinct; Rægneriana, large, deep-green, heart-shaped leaves, forming a beautiful covering for a wall.

All the Ivies are evergreen, and invaluable for covering walls with north or east aspects, old and dead trees, &c., and to form a green carpet beneath trees, and in shady places where nothing else will grow. Ivy may also be employed to give architectural effect. Light, well-drained soil is the most suitable, but it will succeed almost in any soil and situation. Propagation is best effected by cuttings or slips put in at the end of summer in a north border, and kept moist. When quick growth is wanted, rich light soil and liberal waterings in dry weather should be afforded. To have Ivies in their greatest perfection, they require east or north aspects.

Holbollia (Stauntonia) latifolia.—Evergreen, having fragrant green flowers in spring. It requires a south wall, with protection in severe weather, and peat and sandy loam. Increased by cuttings of the half-ripened young shoots in sand under a bell-glass, in a gentle heat.

Jasminum officinale (White Sweet Jasmine).—Deciduous; valued on account of its white sweet-scented flowers. The variety grandiflorum only differs from it in having larger flowers. Jasminum officinale foliis aureis has golden-variegated leaves. There is a kind with white variation, but very scarce, and a double variety, which I believe is not in cultivation. It is remarkable that a bud of the variegated Jasmine taking on the common or green, will frequently cause the whole of the plant to become variegated. To thrive well, these varieties require south-east, south, or south-west aspects, not succeeding on trellises in the open ground. The flowers are produced in July.

J. fruticans.—Deciduous. Flowers yellow; only suitable for low walls. July.

J. nudiflorum.—Deciduous. Yellow flowers, produced in mid-winter. It is so hardy, that in Yorkshire, 500 feet above the sea level, it grows vigorously, and blooms most profusely on a north wall in January. It attains a height of 15 feet, perhaps more, and is a rapid grower. It is very well adapted for forcing or the greenhouse, and succeeds on any aspect out of doors. The flowers are produced before the leaves. It ought to have a place in every garden.

J. revolutum.—Evergreen. Flowers yellow, in June. It is only suitable for south aspects and warm situations, and should have protection in severe weather.

The Jasmines are propagated by cuttings of the shoots after these become firm, inserted under a hand-glass in sandy soil; also by suckers and layers in autumn. Good, rich, light soil, with a little leaf mould or peat, is the most suitable.

Lardizabala biternata.—Evergreen, of rapid growth, and having purple flowers. It requires a south wall, or warm situation. It flowers in winter, and in severe weather needs protection. Soil, sandy loam and peat. Propagated by cuttings of the half-ripened young shoots under a bell-glass in gentle heat.

Lycium barbarum.—Deciduous. Flowers violet, in June. 12 feet.
L. europæum.—Deciduous. Flowers lilac, in June, followed by yellow fruit.
L. afrum.—Deciduous. Violet flowers, in June, succeeded by pretty fruit, of which birds are very fond.

The Lyciums are suitable for walls, trellises, or arbours, being of a free, rambling, half-shrubby nature. They are propagated by cuttings of the ripened shoots in autumn or spring, in a frame or under a hand-glass.

Menispermum canadense.—Deciduous twiner. Flowers green and yellow. June. Suitable for trellises. Cuttings in spring under a hand-glass, division of the roots, and seeds sown in spring. Sandy rich loam.

Mutisia decurrens.—Deep orange-coloured flowers, in autumn. Hardy, but of its other qualities I have no experience, though I think it will prove one of the finest hardy climbers, and an evergreen, being so in a young state.

Passiflora cærulea.—The only hardy Passion-flower, and it requires a south wall, and in cold localities protection in severe weather. Flowers blue and white. Cuttings of the young wood a little ripened, inserted in sand under a bell-glass in gentle heat. Peat and loam form the most suitable soil.

Periploca græca.—A deciduous twiner of rapid growth, and quickly covering an arbour or wall. The flowers are brown, and appear in July. Cuttings in summer under a hand-glass, or layers in autumn.

Vitis vinifera aphylla.—Leaves crumpled or Parsley-like; its only merit.

Vitis heterophylla variegata.—White and red variegation on a green ground, pretty. The Vitises are suitable for south walls or trellises in warm situations. Light rich soil. Cuttings of the ripe wood, or eyes, in a mild hotbed early in spring.

Wistaria (Glycine) sinensis.—Deciduous, and of free growth; foliage light brownish green; flowers light purplish blue, in clusters not unlike bunches of Grapes. A south aspect is most suitable, though it will succeed on east and west walls and other warm situations. It is increased by cuttings of the young shoots when their wood is becoming firm, inserted in sand under a hand-glass or in a frame. Layers, however, form the best mode of propagation. If a young well-ripened shoot, the longer the better, layered its full length in autumn, almost every eye will form a plant or shoot, which will be well ripened and rooted by the following autumn. The variety alba has white flowers.

All climbers should be so trained whilst young that the lower part of the wall or trellis will first be covered, training the shoots out straight and with regularity, and stopping or cutting back, so as to furnish shoots to cover the wall regularly and closely. The shoots, as they advance, must be tied or nailed-up, not so thickly as to crowd and cross each other, but so that each may have a proper share of light, air, and room to grow in. They must, therefore, be thinned-out where too close together, and in tying or nailing allow space for the further thickening of the shoot.

Pruning should be performed at two seasons—namely, in summer and in winter. The summer pruning will in most cases be confined to the regulation of the shoots, thinning them out where too close together, and shortening them where too long. While shoots of some length should be laid-in, there will be far too many for such a purpose, and if they are cut off, the main shoots or branches will be rendered bare; if not required for extension, all but the flowering shoots may be shortened to within a few leaves of their base. The flowering shoots, of course, should be preserved. Wistarias and the like may be closely spurred-in; but the Bignonias, as they produce their flowers on the long shoots, should not be pinched back at the summer pruning, though they may be closely pruned before growth commences in spring. The best method is to secure the covering of the wall, then train-in the shoots where practicable, and if not, to shorten them so as to form an even surface. The winter pruning may be performed early in autumn in the case of the deciduous and hardier kinds, when the leaves have fallen; or, if the climbers are tender, defer pruning until spring. It must be limited to cutting out the old wood, training young in its place, and cutting back the other shoots to within an inch of their base—that is, those not required for extension or covering the wall.

Evergreens will be best pruned in spring before they begin to grow, if much pruning be needed, so that fresh shoots may be produced early, and become well ripened before autumn, or pruning may be performed after flowering. Ivy is, perhaps, the only climber that can be pruned with the shears. The best time to clip it is April; the surface will then be quite green again in a few weeks, and any irregular growths may be trimmed off in August with a knife.—G. Abney.

SUDDEN CHANGE OF TEMPERATURE.

There has been a change of temperature at Blantyre, N.B., from 83° on Saturday, August 28th, at midday in the shade, to 23° on the morning of Monday, August 30th, turning Potatoes black, and giving the gardens an appearance of approaching winter. "Wiltshire Rector," writing from near Chippenham, quotes the temperatures on the same days as 85° and 55°.

Mr. Quintin Read, Pleasley Vale, Mansfield, states that on the morning of August 31st the temperature "was 4° below freezing. In the kitchen garden Vegetable Marrows, Gourds, Kidney Beans, and Potatoes have been destroyed, and in the flower garden Perilla nankinensis, Coleus Verschaffelti, Heliotropes, Dahlias, and Salvias. The Cloth of Gold Pelargonium and Golden Feather Pyrethrum have been much disfigured. Zonal Pelargoniums (except Maid of Kent and Excellent), and other bedding plants, appear to have withstood the frost without being much injured."

Mr. Kerr, writing from Netherby, Cumberland, says, "After a week of very warm weather, the thermometer standing at 80° in the shade on Friday and Saturday, the wind veered to north by east, and on the morning of August 30th the thermometer registered 3° of frost. Dahlias, Perilla, Dwarf Kidney Beans, Vegetable Marrows, &c., have suffered considerably. On the

morning of August 31st the thermometer registered the same temperature—viz., 3° below freezing."

NOTES AND GLEANINGS.

The total number of visitors to the Royal Horticultural Society's Gardens on August 26th, the anniversary of the late Prince Consort's birthday, was 60,870. This year, had it not been for the efficient services of the metropolitan police, the gardens would have become the rendezvous of the costermonger and cheap jack. The "dodges" tried on by these at the gates were surprising, and a great many passed through, but were soon turned out by the police. It is the mischievous boys that the Royal Horticultural Society want to keep out. We regret to say that another of those beautiful vases on the majolica fountain came to grief by these urchins. The class of people for whom the day was intended keep away, although a few respectable people are to be seen, and the gardens become for the time the property of the roughs. If it were not for the services of the police, who deserve all credit, considerable injury would be done to the Society's property.

—— We received last autumn from America a small parcel of Early Rose Potato which we planted the same day with Ashleaved Kidney, Ten-weeks, Gloucestershire Kidney, and Coldstream Early. As regards earliness, it is not to be compared with either of these, being hardly even a second early. The produce was on an average six good-sized and eight small tubers to a stock. When cooked they boiled beautifully white, and were mealy outside; but inside they were close and watery (not even waxy), and the flavour rather disagreeable than otherwise.

WORK FOR THE WEEK.

KITCHEN GARDEN.

The advancing crops of winter *Broccoli* and *Borecole* should be kept frequently hoed, and vacant ground may yet be filled up with the later kinds. The autumn *Cauliflowers* and *Broccoli* planted in shallow trenches should have these filled up, for except in very dry situations the natural rains will afford sufficient moisture. In earthing-up *Celery*, the greatest care is necessary to prevent any portion of the earth from falling into the heart of the plant, which would prevent the upright growth of the inside leaves, and spoil its appearance for the table; nor should the earth be pressed too closely round the upper part of the plant, as frequently, when this is done, it bulges out below. The best practice is to tie each plant loosely with matting, after removing the suckers and small leaves, and then a little earth can be added every week as the plant grows taller. Another common error, is earthing-up Celery too soon. It should be allowed to grow to a considerable size before earthing-up is attempted, and the ground should be frequently soaked with water, as but little rain will reach the roots after earthing-up. The plants should never be touched when at all damp. *Cardoons* will require similar treatment. *Leeks* in drills may have earth drawn to them with the hoe. *Onions* must be stored in a dry state, or they will not keep. As time permits, the *Potato* crops may be taken up, beginning with the earliest kinds first. Late *Peas* and *Beans* will require close attention to prevent mildew; well supply the former with liquid manure. *Tomatoes* are likely to be late, and the leaves shading the fruit should be removed; prevent the plants making any further growth, by constant stopping. On dry days, when the ground is in working order, take up and store roots, stacking them in sand in a cool place, whence they can be conveniently taken when wanted for use.

FRUIT GARDEN.

For the last time go over Peaches and Nectarines, and nail or tie-in further growths, at the same time removing any very weak or excessively strong shoots not wanted for fruiting next season. The remaining shoots, being thinner, will derive greater benefit from the sun's rays increasing the temperature of the wall. Remove leaves where they prevent the fruit from properly colouring. The best kinds of Plums and Nectarines should be protected from wasps and flies by some kind of hexagonal netting. Continue to tie-in and stop Fig trees and Vines on walls, and protect the fruit as above. Look frequently over Pears and Apples ripening, and gather those fit for storing. Where Currants are closely netted up, the trees should be uncovered occasionally on fine dry days, so as to expose the fruit thoroughly to air, in order to prevent injury from damp. Trim and dress Strawberry plantations.

FLOWER GARDEN.

Unless some precautions be taken to keep the taller plants in the beds of geometric flower gardens within proper limits, they will be likely, towards the end of the season, to become too high, and will destroy the uniform appearance essential to this style of gardening. Plants likely to exceed the standard height should, therefore, be constantly watched; and by frequently pinching back or pegging-down, endeavour to keep beds of the same pattern at the same height. At this season beds of flowering plants require frequent cutting back and trimming, to prevent a straggling habit in free-growing plants, a tendency which the late rains will also increase. Allow no dead flowers or seed-pods to remain on the plants. By careful attention to these matters, the season of blooming may be prolonged till the plants are destroyed by frost. Lawns should be well swept in dry weather to remove wormcasts, and should afterwards be well rolled. Where worms are very troublesome, water with clear lime water of full strength, this will bring them to the surface, when they may be destroyed. Cuttings of various evergreens should now be planted to keep up the stock in the reserve garden. It will soon be time to house tender plants from which cuttings are to be taken next spring, or which are to be used again next season. Variegated Pelargoniums will not bear much frost, and where plants have to be wintered in situations which are not very suitable for them, they should be taken up before they are at all injured, as they will be more liable to damp, and to die back in winter, if the wood be at all touched by frost. Except where there is a sufficient stock of the variegated sorts, they should not be cut back, as is usually done with the old scarlets, but should be kept over the winter just as they are lifted from the beds, and cut back early in spring after starting them into growth. The cuttings will then root very freely in heat, and in the case of Flower of the Day, or other free-growing varieties, will make plants of a useful size by turning-out time, and even the strongest growers of these do not cover a bed very quickly unless planted thickly. The plants should, therefore, be wintered in as large a state as the accommodation will permit. Rooted cuttings of Verbenas, and other plants, must be well attended to, keeping them perfectly clear of green fly, and exposing them freely to air on every favourable opportunity, so as to prevent growth after this season, and keep the plants hardy, in which state they will be much less liable to die off under a week or two of confinement in winter, than if they were kept in a growing soft state until overtaken by severe weather. Cuttings which are not sufficiently established must, however, be treated somewhat more tenderly, and should have a gentle bottom heat to encourage roots, but do not keep the atmosphere close or moist.

GREENHOUSE AND CONSERVATORY.

In arranging plants in their winter quarters, on no account allow them to be placed too closely together. It should be remembered that but very few plants have as yet perfectly matured their wood, and, consequently, as that process is still going on, they will require air to play freely around them. Plants, too, are expected to bear examination on all sides, and it is impossible to obtain bushy, compact plants, if they are allowed to touch each other. On flat stages a few may here and there be elevated on inverted pots, to give a little relief to the mass of green. As from placing the plants further apart, possibly room may not be found for all, the oldest and worst-formed should be set aside to make way for the more choice; and as cut flowers are always in request, the above may be found useful to keep for that purpose, and may be wintered in vineries, pits, or other houses, where they will not interfere with the arrangements. Unless the weather continue dry, Orange trees, if at all large, will soon require to be housed, as if heavy rains occur the soil in which they are growing will be saturated with wet, and the leaves will turn to a sickly yellow, which frequently remains throughout the winter. Before removing them to their winter quarters any that require additional room should have fresh pots or tubs, the present time being the most favourable for the operation. As a compost for the Citrus tribe, French gardeners use a mixture of loam, peat, and rotten dung in a state of black mould; but the whole will thrive in yellow turfy loam, and thoroughly rotten cow dung, mixing a portion of broken charcoal with the mass. Imperfect drainage will soon cause disastrous results. The plants thrive all the better if a little under rather than over-potted. Those not requiring a complete shift should have their drainage examined, and the dryness of the soil noted, in order to regulate the winter treatment accordingly. As soon as Japan Lilies, Gladioluses, and plants of similar habit have ceased

blooming, remove them to the foot of a south wall to ripen their growth, water them moderately till their tops show signs of decay, and the pots may then be laid on their sides till potting time.—W. Keane.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

Onions.—Ours are still too firm to take up, though the leaves are changing colour and drooping. As long as the foliage remains green and the roots firm, it is a pity to sacrifice size of bulb to mere quickness of pulling. Our sample will be very fair, though the Onions will not be so large as if we had had a little rain earlier. In all stiff soils, when large Onions are required, as soon as the winter-stored ones are over, it is well to sow a piece of Tripoli and White or Brown Spanish without delay. Our autumn-sown ones were very large without transplanting this season, but in general we have the best bulbs from those transplanted about March. The great secret of success in doing this well, after the ground is properly prepared, and trodden rather firmly before transplanting, is to take up the roots as carefully, and preserving them of as great a length as possible. Make the hole deep enough with the dibble to let the whole length of the roots easily in, fasten with one stroke of the dibble in the usual way, but only put the roots in the ground, leaving the base of the Onion, if covered at all, covered not more than one-eighth of an inch. Plant deeper, and you have every chance of obtaining huge thick-necks instead of fine bulbs.

In such tropical weather as we had at the end of the week, with not a single cloud to give us a little relief, we advise all who must take up their spring-sown Onions not to leave them fully exposed to the sun any longer than is sufficient to wither the roots, as these are exposed upwards. What further drying the Onions require should be given them in a comparatively shaded place. We have times out of number found fine Onions decaying in winter and spring, from the roasting they had from the sun in the open air after being taken up. Pieces of the Onion thus become blistered, and then the bulb decays, especially when kept at all warm. Many lessen the time of the Onions' keeping from being too careful of them. If the bulbs are kept dry, no frost that we have ever had will harm them. They never do better than when plaited in a string in the old-fashioned way, either plaiting them with their own tops alone, or using a few straws or a bit of string along with them to make them more secure. These strings may be of any length, but they are most useful when the Onions are all sized, and are from twenty to thirty in number. There is no better way of keeping them than suspended from nails in the wall under the projecting eaves of an old-fashioned thatched cottage, where little snow or rain can reach them. The back wall of a shed, open in front, is also a good place for keeping them long and well. Those who are short of close structures from which frost can be excluded, may thus find some rather open dry place in which to store their Onions. Provided there was dryness, we have never known the most severe frost hurt an Onion. Though a great necessary for the kitchen, there is nothing particularly savoury in it to some people; but an easy mode of keeping the Onion long sound is a matter of importance to many labourers, who could not get on as they do without their large raw Onion as a help to their dinner when too far removed from their own cottages. In many cases their carefully harvested Onions shoot prematurely in spring, from being kept too warm in winter. Bear in mind that the openest and coolest place will be the best if it be but moderately dry.

We must take up a part ere long to make room for our first Cabbages for spring. Meantime we have turned out three successions of Coleworts, the first about ready to succeed the Cabbages. Our main Cabbage plantations of last autumn, besides giving some good second-crop Cabbages, are now densely covered with fine young sprouts, and would be greatly benefited by manure-watering as soon as we can give it to them. We never found the strongest sewage do them much harm, as it requires some time to reach the roots, and is most effective when applied to the ground before a good rain or heavy shower. The decayed large leaves act very well as a mulching, if better cannot be had. We have been obliged to mulch Cauliflowers, Peas, Beans, &c., as the heat was so excessive. Watering in such weather was out of the question, unless it could be applied so effectually as to reach all the fibres of the plants.

Watering.—Several cases have been brought to our notice, in which plants have fairly succumbed in this broiling weather, owing to a mistaken kindness. "A" has only a limited allowance of water, but the leaves of his plants flag, and he runs along the rows, giving a little to-day and a little to-morrow, and the following day the plants look worse than ever, and ultimately succumb, after all the attention paid to them. "B," after pursuing a similar course, is perfectly astonished on taking up the plants to find the roots of most of them thoroughly dry. If all these waterings had been given in one soaking, and the surface stirred or mulched directly afterwards, the plants might have withstood the scorching, and never been injured. Wetting the surface merely encouraged surface-rooting, and the roots there formed were shrivelled up by the next day's sun. The bulk of the roots was never reached, and what is worse, whilst evaporation was carrying off moisture in vapour from the foliage, the roots, as a whole, were rendered powerless to absorb moisture from beneath, as the surface-watering had paralysed for a time their full action, and until the surface soil becomes dry again, the roots deep down derive no advantage, or but little, from the reservoirs of moisture stored up beneath them. Our Wheat fields always yield best after a dry summer; yet the Wheat plant cannot perfect itself in mere dry soil, but the roots go down a long way after moisture, and the free radiation of heat from the surface enables them to appropriate it as it passes the fibres. A few very slight showers, though at first seemingly refreshing, do no more real good, except from the cloudy atmosphere, than mere surface-watering. Many and many a time we have looked on quarters of Cauliflower, and fields of Turnips, withstanding a fierce sun, and the soil at the surface dry enough, and there has come a gentle refreshing shower that has cleaned the foliage, though doing little more than laying the dust; and often on the following day, when the bright sun came out, we have noticed that the leaves would flag for a time, though they stood up boldly before. The slight shower, like our mere surface-waterings, had arrested for a time the rise of vapour from beneath. In our fields and gardens, it is not always true policy to water when a plant shows a little distress. A little flagging of the foliage will often take place when there is abundance of moisture at the roots. The flagging may merely be the result of a sudden change of weather from dull to bright, in other words, from a very languid evaporation to an extremely active evaporation of moisture from the foliage. The foliage at once responds to the sunbeam, but it requires a little time before the roots, previously in a comparatively inert state, can be aroused into such activity as to absorb sufficient to meet the demands on the expanded leaves. Hence, as respects tender plants, it is often better to arrest the rapid evaporation or perspiration, instead of giving deluges of water where the roots are moist enough already. In the case of many hardy plants, say a quarter of Cauliflower, if satisfied there is moisture at the roots, the little flagging and drooping under such circumstances is of no consequence. When the sun declines in power and sets, the leaves will recover, and will resist a second and a third day's sun much better than the first. It is quite as possible to kill plants by ill-timed, injudicious, frequent watering, as by giving them no water at all. Plants when well established out of doors, would often do better afterwards if they never had any artificial watering.

Mushrooms.—As the material came in so useful for mulching and other purposes, we have been glad to clear out all our beds in the Mushroom house, with the exception of one piece which has continued in bearing, but we shall remove it shortly, as we have been gathering some time from the shallow beds in the open shed in a shady place. Our Mushroom house is a very common affair, made of wood, which often needs repairing, and harbours more enemies than slate would do. As soon as it is cleared out we shall smoke the house with sulphur and a little turpentine, and then whitewash the walls. The lean-to shed has a sloping ceiled roof of the same slope as the ontside roof, and we generally, every two or three years, paint the former thinly with boiled oil, instead of whitewashing it. Our reasons for this are chiefly two. If in making fresh beds, whilst others are bearing, there should be any moisture from the manure condensed against the roof, it trickles down to the front wall, and does not fall or drop on the beds. However well the lath and plastering of such a roof may be done, the steam and vapour from the manure will in time penetrate the best plaster, and when that is the case, the lath and woodwork will soon decay and fall down, most likely when least expected. If the roof were coated with Roman or with Portland cement, probably no moisture would penetrate; but we have found that

a mixture of the cement and mortar will not keep it out. The oil—and when heated it does not take much—has saved us from such casualties for many years. We may mention that the roof is closely boarded for the slates, and the space between the lath and boards is stuffed with clean wheaten straw, and after many years the straw seems as dry and clean as when it was put in.

So much for a very common Mushroom house. We may have a little prejudice for shelves in such a house on the Oldaker system, and there is at times an advantage in having a raised bed in a house, as being more under command than one made on the level. The chief advantage of all raised shelf beds is having so many beds in so small a space, but at a great waste of labour in carrying and lifting the material. Our correspondent, "Forward," does not like the idea of wood always rotting and going to pieces for beds, and wants to know what we should think of iron. We prefer slate or flagstone for constant wear, and permitting always of cleanliness and neatness. Iron, however treated, will be sure to rust. If we had our choice, and were making a Mushroom house, we would have a low house, such as one in which we could merely pass along to carry in the materials with a barrow, &c., without the trouble of lifting or carrying, and we would have the beds entirely on the floor, with or without a slate, stone, or brick-and-cement siding, or edging. Be the roof lean-to or span—in the latter case the pathway under the ridge could be sunk, so as to have the house low—we could have piece after piece on the ground, and have no trouble or expense with shelves, which are always costly, of whatever they are made.

We spawned our third piece in the open shed. These beds were formed chiefly of rather long litter, with 4 or 5 inches on the surface in which droppings predominated. We have a heap of rather long litter fermenting now, which when turned once or twice will form the basis of some of our beds in the Mushroom house, and then that will be covered with a layer chiefly of droppings mixed with rough fibrous soil. We should like quite as well if for shallow beds we had more droppings, but in general our gatherings are regular and abundant. One of the best beds we ever had in the open air was formed chiefly of stubble, litter, and a few tree leaves thrown together, and watered so as to ferment, but on the whole it was dryish rather than very wet. This was surfaced with 2 or 3 inches of droppings, and bore long and abundantly. The great point is to avoid too much heat for the spawn. The next is not to starve the spawn with dryness, nor destroy it with moisture. Where there is room and time, we prefer the droppings to be moderately dried without heating much before being used, but we have scarcely been able to see the difference in results when we have thrown them in a heap to dry themselves by fermentation, and even when very damp, and mixed with cut dry straw to cause them to heat and dry themselves sooner. We know we thus lost much of the most nutritive part of the manure, but so we do when we spread it out thinly to be dried by the atmosphere. In fact, we have known material for Mushroom beds turned, and dried, and turned again out of doors, until there was scarcely any nutritive matter left in it; and thus the Mushrooms, when produced, were little better than if the spawn had been inserted in the open soil, if that was at all good. Though the material should not be wet, neither should it be dust dry; many beds are starved by the dryness of the material. When fleshy Mushrooms are wanted, a slight casing before earthing-up, with sweet moist cow dung will be of great assistance; but too much will make them so thick that it will be difficult to cook them thoroughly without cutting or slicing them, which militates against their appearance at table. It matters little how thick the Mushrooms are when chopped up for flavouring, and Mushrooms are thus often largely used when their presence, except for flavour, would not be detected.

Mushroom Spawn.—It is now a good time for making spawn in dry weather. We have more than once given detailed instructions. Thin cakes are more easily managed than thick ones, as they become dry enough much sooner. Where only a little, or even a few bushels are wanted, it is in every way best and cheapest to purchase from a nurseryman. We know of nothing that has made greater progress than the making of Mushroom spawn, nothing that shows more thoroughly the advantage to be derived from the division of labour. Once in our younger days there was a great inducement to make Mushroom spawn at home. We have had hampers sent from long distances, and it was only worth its weight as a second-rate manure. Now we rarely see a bad cake or brick of spawn turned out. We say this all the more readily because, though we know many firms that would not send out what was not good, we do not know one of the large makers from whom these nurserymen and seedsmen receive the spawn, for very few of these, we believe, make their own. If any try to make it for themselves, by attending to the details previously given, they will find out that the same close attention will be required for a few bushels as if they made some thousands of bushels. It is in this way that the large maker, on the mere principle of the division of labour, will ever be able to make and sell more cheaply than the small maker can. Still, it is well to be able to make Mushroom spawn.

FRUIT GARDEN.

We should have liked to have watered some dwarf Apple and Pear trees in the open air, but we found it beyond our reach. We have no doubt that these trees will be equally fruitful and more healthy next season. This year they have dropped their fruit, in some cases rather beyond the thinning point, and the foliage still shows traces of the awful scorching the trees had last season. Though the buds are looking healthy, the foliage has not the fine deep green it used to have. Besides watering our houses, and syringing walls, as a relief after these hot days, our chief work has been planting-out and potting Strawberry plants for forcing. At the end of the week we slightly shaded orchard houses and the Fig house with whitened water, merely throwing it on slightly with the syringe. This greatly moderated the heat, and rendered watering less necessary. Sprinkling the paths and floors did much to keep an agreeable coolness.

ORNAMENTAL DEPARTMENT.

We have been potting, and cutting-making for the flower garden. We have put in our first batch of Verbenas, &c., are following fast with Variegated Pelargoniums, and will proceed next with the zonal and plain-leaved kinds, using chiefly shallow boxes—say 2½ feet long, 1 foot wide, and 4 inches deep. We become every year fonder of simple methods. We seldom use anything for these boxes except sandy loam riddled, the riddlings to go at the bottom, and a sprinkling of sand on the surface. For the sake of economy, we find pots and boxes better than inserting the cuttings in a border, as we thus save the trouble of lifting, and either potting or boxing. We have put some hundreds of Centaurea in small pots singly, or two in a 3-inch pot, with a piece of slate between them. We shall find a frame or cold pit warm enough for all such cuttings, Verbenas, &c.; and the open air will do for Pelargoniums of all kinds, only if a little shaded and protected they will not flag, though that with good strong cuttings is of little consequence.

In the pleasure grounds, in using the mowing machine, we passed over the grass lightly, as we were afraid to cut too closely, in case this weather should continue; this day (August 28th) being excessively trying, but a falling barometer leads us to hope for a change. People continue telling us, Give us general principles, if you like, but give us the details of your own practice. To-day we have watered nothing in the flower garden, except some lines of Salvia fulgens, and some edgings, very pretty ones, of the purple-leaved Oxalis. Calceolarias are still very fine without watering. Scarlet Pelargoniums have long prevented any ground being seen. We knew they were very dry at the surface, but then the roots were going down after moisture, and, except in the hottest part of the day, showed no signs of distress. A surface-watering would have done no good, and especially in such cloudless days. If the weather, as we expect, prove cloudy next week, or even if a few passing gentle showers should come, we shall most likely water Calceolarias. We attribute the plants' standing the heat and drought so well chiefly to mulching when we thought the soil had become warm enough. Some visitors who have discarded Calceolarias, begin to see that a garden is tame without the yellow, and we have reason as yet to be satisfied with ours. Last season was very trying, because after our hottest and driest days we had no dew at night. Moisture seemed to have bid us good-bye; but after the hottest days of this week the clear sky at night was accompanied, as we generally expect it to be, with a heavy deposition of dew, which filled out the tissues of the stems and leaves. The wise laws of compensation often come in to our aid. In a hot, sunny day there is more vapour generally in our atmosphere, and then how grateful is the gentle refreshing dew in a clear, calm night. To end almost as we began, we have heard of some flower gardens that are not what they used to be, and yet the water has been abundant, and used most unsparingly as respects frequency, and often in large quantity. We believe if the plants had

been watered much more seldom that they would have thriven better. In dusty, exposed places a slight syringing overhead is different from always drenching the roots.—R. F.

COVENT GARDEN MARKET.—September 1.

Large quantities of the coarser descriptions of vegetables and fruits are supplied and exchange hands freely. The supply of good Plums, with the exception of Victoria, is unusually short; and owing to the heavy importations of foreign varieties, high prices cannot be obtained. Apricots seem to have gone altogether for this season. Potato trade dull.

TRADE CATALOGUES RECEIVED.

Downie, Laird, & Laing, Stanstead Park, Forest Hill, London, S.E., and 17, South Frederick Street, Edinburgh.—*Descriptive Catalogue of Dutch Flower Roots.*

George John Child, 49, Darley Street, Bradford, and Bradford Nurseries, Shipley.—*Catalogue of Dutch Bulbs, &c.*

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely to The Editors of the Journal of Horticulture, &c.*, 171, *Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

Seedling Plum and Apple (*W. Champion*).—Neither your Plum nor Apple is good enough to be introduced as new and desirable.

Williams's Bon Chrétien Pear (*Old Subscriber*). — It should be gathered before it becomes yellow. If allowed to ripen fully before gathering, it turns mealy and decays at the core.

Fungus on Plum Leaves (*Clericus*).—The fungus on your Plum leaves is Puccinia prunorum, *Lk.* The yellow base is the early Uredo form of the same species. It occurs, we believe, wherever Plums are cultivated. —M. J. B.

Gooseberry and Currant Trees after Fruiting (*Amateur*).—You need not do anything to your Gooseberry and Currant trees for the present. Let them ripen their wood, and prune them in winter in the way we intend shortly to explain at full length.

Pruning Bush and Pyramid Fruit Trees (*Idem*).—If your trees have been properly attended to in respect to the summer pinching, they should require but little pruning. You may, however, shorten some of the shoots any time after the fall of the leaf; then pinch the points of the growing shoots as they appear, in the same way as we continually recommend in these columns. Before transplanting, give your tenacious soil a liberal dressing of unslaked lime and burnt soil, so to render it a little more friable.

Peach Leaves Injured (*Vicar*).—We incline to think that earwigs and woodlice are attacking the leaves of your Peach trees, and Beanstalks, &c., would be good traps. We discovered a few red spider; and plenty of the syringe, and weak, clear, soft-soap water would be the quickest cure, unless you used Gishurst, after making it and allowing it to settle in a pail before putting it into the engine or syringe-pail. The curl and blister at the points of the shoots show there is a want of reciprocal action between roots and shoots; these blistered parts should be removed, nothing will make them healthy again. So much for the first look at the leaves. On examining them more minutely, we fear that fungus will be found at the roots, and if so nothing will cure it but a little sulphur in the soil, which should be removed from the roots when these are at rest, replacing it with fresh sandy loam.

Grapes Colouring Without Swelling (*An Old Subscriber*).—Your case of usually productive Vines, now refusing to swell their berries before colouring, is one of those apparent mysteries which it is most difficult to account for. Perhaps the tendency to shrivel and shank in the earlier house may form some clue as to the cause, and as the Vines are so healthy, it is not likely that the same result would be repeated. We throw out the idea that the crops of previous years may have somewhat exhausted the fruitfulness of the Vines, and as the later houses chiefly suffer, we should be inclined to think that the wood had become overindurated in the excessive heat of last summer, with, perhaps, an insufficient amount of moisture at the roots. We have suffered a little in a late vinery, and more particularly in a late orchard house, and we think from the latter causes, as the early houses had more attention as to moisture, &c., than the late ones could have, when we could scarcely keep them alive in the excessive heat.

Cultivating Mushrooms in the Open Air (*Vicar*).—What are your resources, the position of the place, or the circumstances in which you propose to cultivate? for without knowing these we might specify many modes, and yet not one of them suit you. For instance: we have inserted spawn in a piece of ground, much as we would Potatoes, 2 inches deep from the surface, beat the ground rather firm, and covered it with a little litter to keep the place in a medium condition of heat and moisture. We have done the same, drawn out a ridge as for dwarf Peas or Beans, put in from 3 inches to 6 inches of horse droppings, in these inserted the spawn, and covered up as above. Again, we have used a deeper furrow or trench, treated it in the same way, and 18 inches on each side sowed with Altrincham Carrots, and by the time the Mushrooms appeared, the Carrots kept them sufficiently shaded to render it unnecessary to have any litter. We have also had good produce in beds in the open air intended for Vegetable Marrows and pickling Cucumbers. In all cases, however, where large continuous gatherings were wanted, we would make regular beds in the open air, say of litter and horse droppings; if on the flat, from 12 to 18 inches deep; if in the ridge form, from 30 to 36 inches wide at the base, and almost as high to the apex. In both kinds of beds the Mushrooms must be protected from the changes of the weather, as too much dryness, too much moisture, and too much heat are equally prejudicial to the Mushroom. In the hottest days in summer and autumn, with the thermometer ranging from 85° to 90° in the shade, we have had the surface of these ridged beds, and in an open space too, not more than 62°, owing to the rough litter keeping off the heat, assisted, too, in this respect at times by a sprinkling of water over the litter, which tended to cool the bed and produce a moist close atmosphere close to the surface where the Mushrooms were. The advantage of a shed open on all sides, or on one side, or even closed all round, is chiefly this, that you have your bed so far protected from heavy rain, snow, &c.

Lucern (*T.*).—By all means plough it up and sow again; or if you would rather not, give a dressing of superphosphate of lime or wood ashes.

Basket Plants for a Greenhouse (*W. E.*).—Convolvulus mauritanicus, Saxifraga sarmentosa and S. Fortunei, Sedum carneum variegatum, Campanula garganica, and Tradescantia zebrina.

Sedum carneum (*T.*).—It is hardy in light, sandy, dry soils, especially in soils which are gravelly; but in heavy, wet ground it is liable to injury from frost, and sometimes perishes. The variegated form ought to be wintered in a cold pit or greenhouse, hardened-off, and planted out in spring, but it survives the winter in open, well-drained soils. It forms a fine edging to a flower bed. We winter it in a cool, dry pit, where it needs no water all winter. It is readily propagated by cuttings in sand during the summer. To winter the plants thus obtained, they ought to be well rooted by September, potted in poor sandy soil, and well exposed before severe weather sets in.

Spring Gardening (*P.*).—With the common Primrose, white and red Daisies, common and variegated Arabis, you will be able to make a tolerably good display, if you have Crocuses, Hepaticas, Winter Aconite, and Snowdrops, all of which will flower some time before those you name, and the Tulips and the plants first mentioned will succeed them. We would add Alyssum saxatile, Aubrietia deltoides, and the Aucuba-leaved Daisy. Of annuals you may now sow Silene pendula, Limnanthes Douglasii; Candytuft, purple, crimson, and white; Erysimum Peroffskianum, Virginian Stock, Saponaria calabrica, and Eschscholtzia californica; and if the winter be not unusually severe they will be very useful for blooming next spring and early in summer. We have found them withstand the winter farther north than you, and in a more smoky town than Manchester.

Propagating Stachys lanata (*Idem*).—You may sow the seed now in sandy soil in a warm situation, and keep the ground moist but not very wet. The plants would then, perhaps, gain sufficient strength to stand the winter, and might be planted out next May. The best mode of propagation is by cuttings, or by slips which in most cases have roots partially formed. All that is required is to pare the end smooth below a joint, trim off a few of the lower leaves, and insert the cutting in sandy soil in a shady place now, early in April where the plants are to remain, and throughout the summer. Plants from cuttings are better than those from seed. They do not grow so vigorously, are of more prostrate habit, and of far better colour. Stachys lanata is an excellent plant for carpeting, edgings, and broad lines, especially in shady positions. Plants are not expensive. In some places cuttings could be had by the cartload.

Pelargoniums Stanstead Rival and Lady Hawley.—In the Floral Committee report, page 144, the colour of Stanstead Rival should have been stated as dark crimson, that of Lady Hawley as light orange scarlet

Wintering Pelargoniums (*R. S.*)—In your case, when you have a heated conservatory, all you have to do is about the beginning of October to take up your Pelargoniums and put them in pots suited to their size, and store them in the conservatory. They will bloom all the winter. The cuttings, which should be taken off now, will serve for bedding-out next season.

Lynmouth and Ilfracombe (*An Old Subscriber*).—They are the most beautiful English sea-coast towns we know. You will have no difficulty in obtaining admission to the gardens near. They are open to the public on certain days weekly. You will see some notes in our Journal on the combes there shortly. Lynton and Lynmouth just now are overflowing with visitors.

Cacti and Mesembryanthemums for Window Culture (*Salopian*).—Of succulents for the window, we would select of Cacti, incurva, tenuifolia, and aristata; Cereus speciosa, Malkisonii, flagelliformis; Cactus Melocactus; Sedum Sieboldii; Sempervivum arboreum and tectorum; Echeveria gibbiflora Crassula coccinea; and the following Mesembryanthemums or similar ones—viz.:—Mesembryanthemum calycinum, densum, crassifolium, filamentosum, floribundum, glauce-cens, lævigatum, rubro-cinctum, sarmentosum, serrulatum, subulatum, and virgatum. These trail less or more, all will be easily managed, and will need to rely entirely on the dew they may be grown in sandy loam with a little brick rubbish and leaf mould. They should have good drainage, and be potted firmly.

Management of Blandfordia flammea (*J. B.*).—The Blandfordias are Liliaceous plants like the Hemerocallis, with evergreen foliage. B. flammea is a strong-growing bulbous plant, from Australia, and should, like the Hyacinth, receive but little moisture after the leaves fall until growth again commence.

Flowering Æschynanthus grandiflorus (*Idem*).—Give a little sweet rotten cow dung, and some loam and heath soil, in addition to your sphagnum and crocks. In winter give little water, and in spring and summer you may expect free-flowering. Either the soil is too poor, or you have kept the plant growing constantly without any resting period. If the rest can be conveniently given in a bright autumn so much the better. The rest then would be as much sun as possible, and as little water as would keep the plant from flagging.

Carnation (*A Lady in Cheshire*).—It is no novelty. We cannot name the varieties of florists' flowers.

Gardening Arithmetic (*J. T. B.*).—Since you do not consider the problem solved, we presume you already know the solution. However willing we are to give information on all gardening subjects, you must not ask us to occupy our time in working sums in simple arithmetic.

Nurserymen's Hours (*G. B.*).—Some of the nurseries about London close at five on Saturdays; but we know of no rule to that effect. It much depends on the nature of the business of the establishment.

Rendle's Plant Protectors (*C. A. R.*).—See last number. Further particulars are the province of an advertisement.

Riddell's Slow Combustion Boiler (*G. Brown*).—It is good, but all boilers may be made slow-combustion if suitably treated.

Heating a Small Greenhouse (*An Amateur*).—As we know nothing of the dimensions or other circumstances, we can only give a general answer. On the score of economy, we would prefer a flue to a boiler, and one of the best modes of having the flue would be to have it below the floor, so that the tile covering would form part of the flue. For cleanliness, however, the hot water would be best, and a saddle boiler of a small size—say 20 inches by 14 by 14, costing about 50s. would suit you.

Names of Fruits (*Pomona*).—Williams's Bon Chrétien. (*H. Foy*).—*Apples*: 1, Keswick Codlin; 2, Hawthorden. *Pears*: 1, Beurré d'Aremberg; 3, Glou Morceau; 5, Dunmore.

Names of Plants (*Ah*).—We cannot undertake to name plants from their leaves only. (*M. C.*).—*Empetrum nigrum*. (*Old Subscriber*).—*Clethra alnifolia*. (*T. H. C. D.*)—No. 1, Atropa Belladonna; 3, Medicago sativa; 2, Impossible to name from the scrap sent. Forward a more complete and further-developed specimen. (*Carofine*.—Impossible to name from a single leaf. (*W. E.*).—1, Too young to determine; perhaps Pteris excelsa; 2, Polystichum aculeare; 3, Not a Fern.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the week ending August 31st.

Date.	Barometer.		Thermometer.				Wind.	Rain in inches.	General Remarks.
			Air.		Earth.				
	Max.	Min.	Max.	Min.	1 ft. dp.	2 ft. dp.			
Wed... 25	30.175	30.151	84	50	63	60	S.E.	.01	Foggy; very fine; clear and fine at night.

POULTRY, BEE, AND PIGEON CHRONICLE.

LIGHT BRAHMAS, AND CROSSING THEM WITH DORKINGS.

In a recent number of your Journal Mr. Warren, the obliging and active Honorary Secretary of the Southampton Show, was good enough to refer to my efforts to get justice done to the Light Brahmas by obtaining a separate class for them at the leading shows, and also by getting up cups to be freely competed for by all breeders of that variety. As one who has stood by them all along, and who recognised their beauty and usefulness when they had few friends, it is very gratifying to me to see how popular and numerous the Light birds have become. Mr. Warren calls attention to the fact, that at Southampton little short of £20 has been raised for extra prizes by the Light Brahma-breeders; and, as another fact, I may mention that at Birmingham, in the last three years, the Light Brahma-breeders have contributed no less than five pieces of plate, amounting in money value to about £30. The Light Brahma-breeders felt that, having done so much, besides paying heavy entrance fees, they had some claim on the Birmingham authorities, and it was proposed this year again to raise a cup by subscription if the authorities would contribute another from their funds. Although the Birmingham Council have given cups out of the show funds for other breeds of poultry, the supporters of which breeds had not themselves contributed any cups at all. I regret to say that the proposal of the Light Brahma-breeders has not been accepted, and I am afraid we shall not see a Light Brahma cup at Birmingham this year.

In other quarters the prospect is more cheering. We have a new and potent ally in Mr. Rodbard, who is getting up cups for the Light Brahmas at Bristol, and Mr. Crowley is doing the same good work at Southampton.

As a proof of the increased and increasing popularity of the Light Brahmas, I may add that at several recent shows they have formed the most numerous classes. At the Bath and West of England Show at Southampton, with equal prizes offered, there were sixteen pens of Light Brahmas to eight of Dark, or exactly two to one. At Reading the Light Brahmas outnumbered every other class in the show. At Ipswich twelve Light cocks were exhibited against eight Dark. In these cases, also, the prizes offered were equal.

Allow me, before concluding, to confirm the remark of your correspondent, "E. M. B. A.," as to the value of the cross between the Dorking and Light Brahma for table purposes, and this I can best do by an instance within my own knowledge. I well remember sending my famous old cock, "Sampson," which some of your readers remember, and whose victories at so many shows were duly recorded by you at the time, to a run at a neighbouring farmer's, who kept Dorkings. When the London higgler appeared to buy the farmer's chickens, he said at once, "Your chickens are finer, and worth more money, than they were in former years." The farmer obtained a better price, and to the day of his death borrowed one of my Light Brahma cocks to run with his Dorkings.—John Parks.

COMPOUND FOOD FOR FOWLS.

As far as I can understand "E. M. B. A.," the great and only objection he has to the food is, that once used it becomes to the bird a necessity of existence. I hardly think the comparison which "E. M. B. A." institutes between the effects produced by my food on chickens, and that of brandy on the human frame, will hold good. What would be the consequence of daily administering stimulants to an infant? Should we find rapid growth and development, perfection of form, the various functions of the body healthy, and vigorous offspring? or should we not rather find debility, stunted frame, premature maturity, early decay, and a total inability to perpetuate the species? Yet the first are the effects of my food, and "E. M. B. A." does me the justice to say, "unquestionably it is good for chickens," and the only objection he can take to it is that, once used, fowls will not, or rather cannot do without it. This

ought not to be an objection, provided economy is not neglected and success ensured. I need hardly point out more than one fact to you to entirely disprove this theory of "E. M. B. A." At the present moment there are thousands of Pheasants which have been reared on the food till fit to go into the covers, and are then turned out in great part to forage for themselves. What difference can exist between the Pheasant and the fowl? If any, it is simply this, that whilst the Pheasant, used to the soft lap of luxury, and turned out to roam and forage for its existence, is, to a certain extent, exposed to the variations of temperature and season by day and night, the fowl, on the contrary, is provided with nutritious food at stated times, warm shelter, and has every care and attention paid to it on the slightest appearance of ailment. That chickens reared on the food go back when it is omitted in their daily diet is unquestionable, and I think it one of the strongest arguments in its favour.

"E. M. B A." kindly cautions his readers against purchasing fowls which have been fed on my food, as in all probability they will lose them when it is discontinued. I am a large breeder of Game fowl exclusively, and send away some hundreds during the season to parties who never have, and perhaps never will use the food. Every bird of these has been reared on it from the day it was hatched till sent away, and yet is there a purchaser of any of my fowls (and amongst your readers there must be many) who can come forward and say he has lost a single mature bird when deprived of it? or, to go even further, will any fancier who, after a bird has come into his possession as a fresh purchase, say he has found his acquisition droop and die?

Here is the clue to the whole. I can gather from the letter of "E. M. B. A." that he deputes the attention of his "yards" to other people, for does he not say, "I found that Dear's food had been omitted for a week?"—*ergo*, he was unaware of what was taking place for a week. Mr. Wragg, Mr. Loe and myself, are practical men, who personally superintend our yards, see that every order given is rigidly carried out, and that the most minute details of daily occurrences in connection with them are instantly communicated to us. Here is where nine out of ten fail to rear their chickens, or show a winning pen of birds. —H. C. Dear, *North Stoneham Park, Southampton.*

[We have been obliged to omit much from this communication, and must decline inserting any more on the subject.—Eds.]

FEEDING POULTRY.

Of the circumstances under which I have observed fowls healthy and unhealthy, I shall first describe those in which they were in the former condition. This was where they had a free run, plenty of light food—such as mashed potatoes with a little grain, so that the crop was kept well distended, and the contents easily digested—plenty of water, abundance of buttermilk, the latter being beneficial to an irritable constitution, and lastly, the house so ventilated that a candle would burn brightly in it without flickering. Under such treatment poultry lay well, are firm in flesh, and I have scarcely ever found them otherwise than healthy.

I now come to fowls which are shut up part of the day. When partly confined, more green vegetable matter should be given, and less strong food, with an abundance of drink mixed with gelatinous matter. They ought to have their liberty early in the morning, as then is their natural time to seek dainty morsels—in fact, it is the only time they can find them; so that poultry not let out until the after part of the day might as well be not let out at all. Poultry wholly in confinement ought to be fed in the morning with light food partly consisting of green vegetables, plenty of milk and water, and grain, which ought to be crushed, and given only at night as their last meal. When let out in the morning, attended to properly, and much irritating food is not given, fowls are generally healthy. With those wholly in confinement I have found more difficulty; but whenever abundance of milk, vegetables, and clean sand were given, they were healthy. It is vain to expect the same number of eggs from fowls kept in as from those at liberty. Encouragement to lay only brings on disease and shortens life. Such has been my experience.—A Lanarkshire Bee-keeper.

THE HEN FEVER.

Why should not people have the "hen fever?" The hens are happily free from it. From Christmas time to near spring, fresh-laid eggs are worth from 3 to 6 cents a-piece, 40 to 60 cents a-dozen, and rarely less than 3 dollars a-hundred. From May to September, "broilers,"—that is, full-fledged chickens weighing 1 to 2 lbs. each, and usually 3 lbs. to the pair, will sell at from 1 to 2 dollars a-pair, alive.

The demand for eggs is insatiable. The "transactions" in New York alone are estimated to amount to some 3,000,000 dollars or 4,000,000 dollars a-month; and during the cool weather from September to April, the sales in the dead-fowl market, not exclusively chickens, however, probably exceed these figures. The value of poultry-yard products in the whole country is said to be not less than 100 000,000 dollars a year. The best breeds for eggs are not the best as winter layers. The best for flesh are not the best for eggs, nor are those which quickly attain marketable size the best for fattening for the fall and winter market. The most beautiful fowls are found among those famous as layers, yet this class includes also the homeliest. Every breed has its uses, each has its fanciers; some are in fashion now, others will be two years hence.—(*Boston Cultivator.*)

DORKINGS AT THE WHITWORTH AND ROCHDALE POULTRY SHOW.

An observation in the account of this Show in last week's number, to the effect that "the Dorking classes were scantily filled," has led me to look at the catalogue, from which I find that the chicken entries were more numerous than in any other class, with the exception of the selling class. There were, in fact, twelve pens entered, three of which were highly commended, in addition to the two prize-winners. Your correspondent's observation must, I think, refer to the adult class, for which there were four entries only. I question, indeed, whether committees are wise in offering prizes for Dorkings over one year old during the moulting season. Few breeders, unless their yards are very large, can make up a good pen of adult birds from July to October, and the small entry of this class at Rochdale points to the same conclusion.—An Exhibitor.

THE UTTOXETER POULTRY SHOW

This Show was held on August 27th, in a very large tent well adapted for the purpose. The ventilation was excellent, and the shade afforded to the really oppressed poultry was most acceptable. The day was excessively hot, and we regret to say several very valuable fowls died during transit by rail to Uttoxeter; consequently, apart from the money value of the fowls, the pens of which they formed part were rendered incapable of prize-taking. As our pages may be read by some of the railway officials, we would draw attention to the want of judgment shown in stowing as many baskets as possible of the most valuable of exhibition poultry in a van, without ventilation, and exposed to the burning rays of the sun. This, beyond question, is the cause of the serious losses we have named. A proper admission of air to highly-fed poultry, more especially when closely packed, is indispensable, otherwise serious injury, and often death, will be the consequence. Railway managers cannot be too careful on such occasions. We cannot speak more highly than they deserve of the strenuous efforts of Messrs. Banting, Dams, and others of the Committee, in doing all they could, on the arrival of the birds, to counteract the influences just named. The birds being placed in large open pens without delay, and supplied with abundance of spring water, we believe not a single death took place after arrival; though many when they arrived looked faint and almost hopeless. Those found dead on opening the baskets were carefully returned to the owners for their inspection.

The Show was admirable, the Dark *Brahmas* taking a strong lead as public favourites. The *Hamburghs* and Grey *Dorkings* were not less commendable. In a good class for *French* Fowls, Crève-Cœurs were first, and Houdans second, no La Flèche being shown. The *Geese*, *Turkeys*, and *Ducks* were first-rate. The general classes were confined to birds of the present year; but earnestly desirous to meet the wishes of every patron, the Committee wisely added a general class for "Any variety of poultry, irrespective of age." A valuable pen of *Spanish* received the first prize, and unquestionably the very best pen of Golden-spangled *Hamburghs* shown at Uttoxeter the second. The Exhibition was exceedingly well filled, a Horticultural Show being united to it, and the satisfaction of the visitors was freely expressed.

Dorkings (Any variety).—1 and 2, Mrs. Arkwright, Etwall Hall, Derby. *hc*, G. A. Crewe, Etwall, Derby; Miss E. Williams, Heullys Berriew, Montgomeryshire (White Rose-combed); E. Leech, Rochdale. *c*, Rev. E. Bartrum, Great Berkhampstead (Coloured); Lady Bagot, Blithfield Hall (Grey).

Cochin-China (Any variety).—1. T. Rogers, Walsall. 2, J. Robinson, Garstang (Buff). *hc*, G. A. Crewe (Buff).

Game (Black or Brown-breasted Reds).—1, Rev. T. O'Grady, Hognaston Vicarage, Ashbourne (Black-breasted Red). 2, G. Bagnall, Draycott, Cheadle. *hc*, J. Platt, Swanlow, Winsford (Red); G. Bentley, Stone,

Staffordshire (Black-breasted); C. Minors, Sudbury, Derby (Brown-breasted Red); G. Batthew, Uttoxeter (Black-breasted).

Game (Any other variety).—1, Withheld. 2, W. H. Mitchell, Moseley, Birmingham. Extra 2, T. Rogers.

Hamburghs.—*Golden or Silver-pencilled.*—1, Duke of Sutherland, Trentham Hall. 2, Col. Fitzherbert, Somershall Hall. *Golden or Silver-spangled.*—1, T. Bolton, Handford, Stoke-upon-Trent (Golden). 2, Ashton and Booth, Broadbottom, Mottram. *hc*, T. May, Wolverhampton; Duke of Sutherland.

Brahma Pootra (Any variety).—1, Rev. E. Alder, Etwall Vicarage, Derby. 2, C. Layland, Morrisbrook Villa, Warrington. *hc*, A. O. Worthington, Burton-on-Trent (Light); Rev. E. Alder (Dark); E. Leech. *c*, J. Holmes, M.D., Chesterfield (Dark).

French Fowls (Any variety).—1, Miss E. Williams (Crève-Cœur). 2, R. B. Wood, Uttoxeter (Houdans). *hc*, W. O. Quibell, Newark (Houdans); W. Dring, Faversham (Houdans).

Ducks.—*Aylesbury.*—1, E. Leech. 2, Lady C. Sheppard, Crakemarsh Hall. *Rouen.*—1, E. Leech. 2, G. Bagnall. *hc*, J. H. Lasbrey, Uttoxeter.

Geese (Any colour).—1, E. Leech. 2, G. Bagnall (Toulouse). *hc*, G. A. Crewe, Etwall, Derby; G. Bagnall. *c*, F. E. Richardson, Bramshall, Uttoxeter (Toulouse).

Turkeys (Any variety).—1, E. Leech. 2 and *hc*, F. E. Richardson (Cambridge).

Extra Class (Any variety).—1, J. Mansell (Spanish). 2, T. Bolton, Handford, near Stoke-upon-Trent. *hc*, J. Mansell, Longton (Polands); H. Bagshaw, Uttoxeter (Black Hamburgh); G. A. Crewe (Grey Dorkings); A. O. Worthington (Partridge Cochins); C. Layland (Dark Brahma); R. B. Wood, Uttoxeter (Houdans); Mrs. Dring, Faversham (Houdans); W. O. Quibell (Houdans); G. Bagnall (Game); Duke of Sutherland. *c*, J. Bakewell, jun., Uttoxeter (Coloured Dorkings); Rev. T. O'Grady, Ashbourne (Silver-Grey Dorking); S. Bagshaw (Partridge Cochins); Duke of Sutherland.

The Judge was Edward Hewitt, Esq., of Sparkbrook, Birmingham.

BURNLEY POULTRY SHOW.

This Show, which forms a part of the North Lancashire Agricultural Society's Meeting, took place on the 26th ult., and a liberal prize schedule was productive of a good competition. It was held in an open field, and the intense heat of the midday sun was so insupportable that not only were the Judges compelled to rest at intervals, but some of the most ailing of the birds had to be taken from the pens and placed in their baskets in the shade, to prevent sunstroke. A slight protection of some kind from both sun and rain would be a great improvement.

The Grey *Dorkings*, *Cochins*, and *Brahmas* were decidedly the best classes, though the *Geese*, *Ducks*, and Ornamental *Water Fowl* were very good. Mr. Brierley's cup *Game* cock was splendidly shown, but the Game fowls generally were deficient in quality.

Dorkings (Grey).—1, J. Stott, Healey, Rochdale. 2 and *hc*, D. Parsons, Cuerden, Preston.

Dorkings (White).—1, G. and C. Furness, Accrington. 2, D. Parsons.

Brahma Pootra.—1, J. H. Pickles, Birkdale, Southport (Dark). 2, E. Leach, Rochdale (Dark). *hc*, J. Heap, Todmorden. *c*, W. Hargreaves, Bacup (Dark).

Spanish.—1, C. W. Brierley, Middleton. 2, H. Wilkinson, Earby, Skipton. *hc*, H. Beldon, Goitstock, Bingley.

Game (Any colour).—1, C. W. Brierley. 2, T. Wareing, Preston.

Cochin-China.—1, T. Stretch, Ormskirk. 2, C. Sidgwick, Ryddlesden Hall, Keighley. *hc*, Mrs. Wilkin, Bootle, Holborn Hill, Cumberland (Buff); C. W. Brierley.

Hamburghs (Golden-pencilled).—1 and 2, H. Beldon. *hc*, H. Pickles, jun.

Hamburghs (Silver-pencilled).—1 and 2, H. Beldon. *c*, J. Robinson, Garstang.

Hamburghs (Golden-spangled).—1, H. Beldon. 2, S. & R. Ashton, Roe Cross, Mottram, Cheshire. *hc*, J. Newton, Silsden, Leeds. *c*, H. Pickles, jun.

Hamburghs (Silver-spangled).—1, H. Beldon. 2, J. Robinson. *hc*, H. Beldon; J. Robinson.

Poland.—1 and 2, H. Beldon.

Bantams (Any colour).—1, H. Beldon. 2, C. W. Brierley. *hc*, E. L. Waddington, Heasandford, Burnley. *c*, D. Parsons; W. F. Entwisle, Leeds; B. Bee, Goosnargh, near Preston (Game, Black-breasted Red).

Crève Cœur.—1, C. Layland, Warrington. 2, H. Wyndham, Beverley, Yorkshire.

Houdans.—1, W. O. Quibell, Newark, Notts. 2, Mrs. Wilkin.

Single Cocks.—Dorking.—1, W. H. Butcher, Preston. 2, T. Briden, Earby, Skipton. *hc*, D. Parsons, Cuerden, Preston (Grey). Game (Any colour).—1 and Cup, C. W. Brierley. 2, R. Payne. *hc*, E. L. Waddington, Heasandford, Burnley.

Geese.—1, E. Leech, Rochdale. 2, T. Houlker, Revidge, Blackburn. *hc*, Rev. G. Hustler, Stillingfleet, York; S. H. Stott, Rochdale.

Ducks (Aylesbury).—1, M. Seamons, Hartwell, Aylesbury, Bucks. 2, J. Robinson.

Ducks (Rouen).—1, E. Leech; 2, T. Wareing, Preston. *hc*, T. Houlker, Revidge, Blackburn; J. Newton; J. Robinson.

Ducks (Any other variety).—1, C. W. Brierley. 2, A. & T. Trickett, Waterfoot, near Manchester. *hc*, C. W. Brierley.

Turkeys.—1, E. Leech. 2, S. H. Stott.

YOUNG POULTRY.

Dorkings (Grey).—1, Stott, Healey, near Rochdale. 2, T. Briden, Earby, Skipton. *hc*, J. Robinson. *c*, W. H. King, Rochdale.

Dorkings (White).—1, J. Robinson. 2, D. Parsons. *hc*, Mrs. M. Fairhurst, Woodlands, Ormskirk.

Spanish.—1, H. Beldon. 2, H. Wilkinson.

Game (Any colour).—1, J. Farrer, Thorneyholme, Burnley (Brown-breasted). 2, R. Payne, Brierfield, near Burnley (Brown Red). *hc*, H. Martin, Ulverston (Duckwing); J. Farrer (Brown-breasted); J. Carlisle, Earby, near Skipton (Brown Red).

Cochin-China.—1 and 2, C. Sidgwick, Ryddlesden Hall, Keighley. *hc*, J. Robinson.

Hamburgh (Golden-pencilled).—1, H. Beldon. 2, W. Carr, Patricroft, Manchester. *hc*, H. Pickles, jun., Earby, Skipton.

Hamburghs (Silver-pencilled).—1, H. Beldon. 2, H. Pickles.

Hamburghs (Golden-spangled).—1, H. Beldon. 2, No competition.

Hamburghs (Silver-spangled).—1, W. Bairstow, Ferncliff, Bingley, Yorkshire. 2, H. Beldon. *hc*, W. Bairstow; J. Robinson.

Polands.—1 and 2, H. Beldon.

Bantams.—1, G. Anderton, Accrington. 2, W. F. Entwisle, Leeds. *hc*, H. Beldon; E. L. Waddington, Heasandford, Burnley. *c*, W. F. Entwisle.

Geese.—1, E. Leech. Equal 1, Mrs. M. Seamons. 2, Rev. G. Hustler, *hc*, J. Lancaster, Burnley.

Ducks (Aylesbury).—1 and *hc*, Mrs. M. Seamons. 2, E. Leech. *c*, S. H. Stott.

Ducks (Rouen).—1, E. Leech. 2, C. Sidgwick. *hc*, W. Bleazard, Brierfield, Burnley; J. Robinson.

Ducks (Any other variety).—1, A. & T. Trickett. 2, C. W. Brierley.

Turkeys.—1, T. Houlker, Revidge, Blackburn. 2, E. Leech.

Extra Stock.—*hc*, — Wilkin (Paduo Chamois); D. Lord, Stacksteads, near Manchester (Black Hamburghs). *c*, W. Moore, Burnley (Blue Dragon Pigeons); C. W. Brierley (Spanish Geese).

Messrs. Hewitt and Teebay were the Judges.

BIRKENHEAD POULTRY SHOW.

This was held on August 25th and 26th, in Birkenhead Park. The following are the awards made by the Judges, Mr. R. Teebay, Mr. Cox, and Mr. Hindson:—

Dorkings.—1, Viscount Turnour, Shillinglee. 2, E. Leech, Greave House, Rochdale. 3, T. Briden, Earby, Skipton. *hc*, E. Shaw; W. Ravenshaw.

Cochin-China.—1 and 3, W. A. Taylor, Manchester. 2, T. Stretch, Ormskirk. *hc*, J. K. Fowler, Aylesbury.

Brahma Pootra.—1, C. Leyland, Warrington. 2, E. Leech. 3, J. K. Fowler. *hc*, F. C. Haworth, Newfield, Haslingden.

Spanish.—1 and 2, F. & C. Haworth. 3, T. & E. Comber, Warrington. *hc*, R. Davies.

Game.—1, C. Chaloner, Whitwell, Chesterfield. 2, W. Boulton, Dalton-in-Furness. 3, Master J. R. Fletcher, Stoneclough, Manchester. *hc*, Duke of Sutherland, Trentham.

Bantams.—1, T. Sharples, Forest Bank, Rawtenstall. 2, J. Meardle, Liverpool. 3, J. L. Bromfield.

Hamburghs.—1, T. Bolton, Hawford, Stoke-on-Trent. 2, Duke of Sutherland. 3, T. Edwards, jun., Barnton, Northwich. *hc*, A. Hason.

Any other Breed.—1, Hon. H. W. Fitzwilliam, Wentworth Woodhouse. 2 and 3, W. Gamon, Chester (Polish). *hc*, J. K. Fowler (Crève-Cœur).

Game Cock.—1, C. Chaloner. 2, Master J. R. Fletcher. 3, W. Boyes, Beverley. *hc*, J. Statter.

Ducks.—*Rouen.*—1, W. Gamon. 2, S. H. Stott, Rochdale. 3, E. Leech. *Any other Breed.*—1, Mrs. M. Seamons, Aylesbury. 2, E. Leech. *c*, R. M. Townsend.

Geese.—1, Mrs. M. Seamons. 2, J. K. Fowler. 3, E. Leech. *hc*, H. Turner.

Turkeys.—1, E. Leech.

Any Breed.—1, W. Dale.

Pigeons.—*Carriers.*—1, J. Hawley, Bingley, Yorkshire. 2, H. Yardley, Birmingham. *hc*, W. Woolley. *Pouters.*—1 and 2, W. Gamon. *Tumblers* (Almond).—1, F. Dixon. 2, J. Fielding, jun., Rochdale. *hc*, J. Hawley. *Tumblers* (Any other variety).—1 and 2, F. Dixon. *hc*, J. Fielding. *Owls.*—1, Cup, and 2, J. Fielding. *Jacobins.*—1, J. Hawley. 2, H. Yardley. *hc*, J. Hawley; W. Gamon. *Turbits.*—1, J. Fielding, jun. 2, J. Hawley. *hc*, F. Dixon; H. Yardley. *Fantails.*—1, J. Hawley. 2, T. H. Frean, Liverpool. *hc*, F. Dixon; J. Hawley; W. Gamon. *Any other variety.*—1, J. Fielding, jun. 2, H. Yardley. *hc*, G. S. Coombe; F. Dixon; T. Furnival; J. Hawley; J. H. Ivimy. *c*, F. Dixon.

GREEN-HAMMERTON POULTRY SHOW.

This Show, held on the 31st of August, was much larger than any previous one, and the quality of the fowls better. The *Spanish*, *Dorkings*, and *Hamburghs*, were very good.

Spanish.—1, W. & F. Pickard, Thorner. 2, W. Bearpark, Ainderby Steeple. *c*, Miss York, Wighill Park; O. A. Young, Driffield. *Chickens.*—1 and 2, W. & F. Pickard. *c*, H. S. Thompson.

Dorkings.—1, J. & R. Potter, Whixley. 2, W. Bearpark. *c*, Miss Thompson, Kirk-Hammerton Hall; D. W. Brook, Driffield; C. Triffitt, Cattal. *Hens.*—1, D. W. Brook. 2, W. Bearpark. *c*, H. S. Thompson. *Chickens.*—1, W. Bearpark. 2, O. A. Young. Equal 2, C. Triffitt. *c*, T. Seymour, Green-Hammerton.

Game.—1, J. Watson, Knaresborough. 2, W. Bearpark. *c*, J. Watson; O. A. Young; Miss Hawkes, Hunsingore. *Chickens.*—1, W. Bearpark. 2, Miss Hawkes.

Cochin-China.—1, W. & H. Pickard. 2, Miss York. *c*, T. H. Readman, Whitby; J. Walker.

Hamburghs (Golden-spangled).—1, J. Walker. 2, W. Bearpark. *c*, B. Marshall, Knaresborough. *Chickens.*—1 and 2, J. Walker.

Hamburghs (Golden-pencilled).—1, J. Walker. 2, H. S. Thompson. *Chickens.*—1, J. Walker. 2, W. Bearpark.

Hamburghs (Silver-spangled).—1, J. Walker. 2, Miss A. L. Farrer. *Chickens.*—1 and 2, J. Walker.

Hamburghs (Silver-pencilled).—1, J. Walker. *Chickens.*—1 and 2, J. Walker.

Game Bantams.—1, J. Watson, jun. 2, T. Mason, Green-Hammerton. *c*, H. S. Thompson.

Bantams (Any other variety).—1 and 2, J. Walker. *c*, R. Gamble, Boston Spa.

Barndoor Fowls.—1, Miss Thompson. 2, O. A. Young. *c*, J. Cocker.

Nun Monkton; Mrs. Slingsby; C. Triffitt. *Chickens.*—1, J. Cocker. 2, T. C. Buck, Green-Hammerton.

Geese.—1, Miss Thompson. 2, J. Walker. *Goslings.*—1, T. Buck, Green-Hammerton. 2, Miss Thompson.

Ducks (White Aylesbury).—1, H. S. Thompson. 2, O. A. Young. *Ducklings.*—1, O. A. Young. 2, H. S. Thompson.

Ducks (Rouen).—1, C. Graham, Aldborough. 2, O. A. Young. *c*, Mrs. Slingsby. *Ducklings.*—1, O. A. Young. 2, Mrs. Slingsby.

Ducks (Any cross-breed).—1 and 2, J. Walker. *Ducklings.*—1, O. A. Young. 2, T. Buck.

Turkeys.—Prize, W. Firth, Stourton. *Poults.*—1 and 2, W. Cundall.

Selling Class.—1 and *c*, C. Triffitt. 2, H. S. Thompson.

Pigeons.—*Tumblers.*—1 and 2, G. Sadler, Boroughbridge. *Fantails.*—1 and 2, G. Sadler. *c*, J. Walker. *Pouters.*—1, J. Watson, jun. 2, J. Walker. *Any Distinct Breed.*—1 and 2, G. Sadler.

Selling Class.—1 and 2, G. Sadler.

Rabbits.—1 and 2, Miss A. L. Farrer.

Extra Stock.—1, H. S. Thompson. 2, C. Walker, Boroughbridge.

Judges.—Mr. Hutchinson, and Mr. E. Hutton, Pudsey.

RABBITS AND THEIR JUDGES.

If there is truth in the saying, that a man's knowledge of things in general must keep pace with the times (and the knowledge our grandfathers possessed of things in general, and of poultry, Pigeons, and Rabbits in particular, was vastly inferior to ours), I think the poultry-fancier is placed in an enviable position; for, perhaps, there never was a period in the history of poultry and Pigeon rearing and exhibiting when a greater number of competent judges could be found. Their names always inspire the exhibitor with confidence, and prompt him to forward more entries, feeling assured that the points of excellence of the varieties to be decided upon will be observed by a very critical and experienced eye. The varieties are numerous, compared to what they were in our grandfathers' days, when, if one happened to be the owner of a good Game cock and hens, and perhaps one or two more varieties, he was a fortunate man. "The good time coming," I am sorry to say, is yet the hope of the Rabbit-fancier, and, less fortunate than the poultry and Pigeon-fancier, he does not know which way to look for a competent judge of his pets, and they have to be left to the mercy of anyone chosen to award the prizes in some other department of the show. The Rabbits, too, are treated at times in a sort of "anything-will-do-for-them" manner, very unsatisfactory to the exhibitor in its result, and very injurious to any show. If competent judges of poultry and Pigeons will venture an opinion respecting the merits of Rabbits, in justice to the exhibitor they ought to make themselves acquainted with the points of the varieties, just as they have had to do with those of poultry and Pigeons, and not commit themselves, as frequently happens, and thus lay themselves open to censure in consequence of their inexperience.

I am inclined to think that the judging of Rabbits is too little cared for by committees, and no competent judge is provided. This I consider a great injustice to the exhibitor, as he sends his entries in the belief that his specimens will be in the hands of a judge, not of horses, poultry, and Pigeons, but of Rabbits; and when he finds no judge is provided, he very justly complains of the result. I am of opinion that many who decide upon the merits of Rabbits are almost obliged to do so by the secretary or some other of the "powers that be" for the day. I have heard more than one confirm my opinion, by saying that after their real duties were over they had been asked to "look over" the Rabbits, as a sort of "make-weight" or supplement to the arduous duties they were engaged to perform, and which they could carry out well with the knowledge they possessed; whilst the latter was less pleasurable, because they were in doubt as to what they were doing. I know more than one excellent judge of the feathered tribe who has objected to giving his opinion as to the best Rabbits. I think competent men ought to be provided, and I know more than one fully able for the work. If the expense is the objection, that would soon be more than compensated by the increased number of entries, which would be obtained when it was known that a competent judge was to award the prizes. I think competent men might be found within twenty miles of each large show. I am also of opinion that the large breeders and exhibitors of every variety are the most competent judges, as one who exhibits and sees many specimens is generally a critical observer, and I should attach great importance to his opinion.

I would, in conclusion, hint to committees and officers of shows generally, not to exhibit so many specimens themselves. I remember some time ago a show of Rabbits, at which the secretary took nearly one-half the prizes. I admire the decision of some well-known breeders in reference to a show with which they are connected in the north of England, that being not to allow any of their birds to be sent for competition, thus preventing any remarks. I hope some fanciers will state their views on this Rabbit-right question, and suggest a mode of operation for the future, in order to insure justice being done where Rabbits are exhibited.—Himalayan.

DOES THE OLD QUEEN ALWAYS HEAD THE FIRST SWARM?

The above question is one which I have hitherto deemed it almost a matter of course to answer in the affirmative, until induced to arrive at a contrary conclusion, from an incident which has lately occurred in my apiary, and which I mention in case you may think it worth recording in your columns.

On the 2nd of June last one of my hives swarmed, but the original colony remained strong enough to necessitate keeping on a good-sized super for some time afterwards. The hive was one known as "Neighbour's Cottage," but enlarged by me two years ago, to a depth of about 10 inches. It was not long before the bees seemed to diminish in number, and as this retrogression went on, I attempted to account for it by attributing the fact to the extirpation of the drones; but as week after week the condition of the stock became worse and worse, I began to fear that the young queen, which had, as I took it for granted, succeeded the old one, must have met with a calamity while on her wedding trip.

So matters went on until about a week since, when that unfailing sign of a helpless hive manifested itself in the general and continued attack made upon it by robber bees. Having observed before, that in such a case to narrow the entrance, as a general rule, protracts the struggle of defence against victory, but does not avert the destruction of any hive that cannot, under ordinary circumstances, hold its own against all comers, and with a desire, also, to save the robbers themselves from many of them paying a freebooter's penalty, I shut off all communication between the remnant of the colony and the outside world, and at the earliest opportunity I carefully took out and examined all the comb in the hive. First, let me say, there was not a particle of honey to be seen anywhere, and believing that the hive was queenless, I saw, with some surprise, contrary evidence, although this was of the feeblest kind, consisting only of two small patches, one of drone cells, the other of worker larvæ, both of these in all stages from the egg when hardly visible, to the bee just breaking through its covering, suggesting a rate of increase of but two or three a-day. Upon this I searched for the queen and found her with every mark accompanying old age unmistakeably impressed upon her; the legs bent under and carrying their owner as though the effort was a painful one, while the wings were ragged and battered in an extreme degree—an appearance of things which fully accounted for the diminished strength and ultimate destruction to which I have before referred.

Now, this queen's age could not, with every desire to be as polite as possible on the delicate subject, be reckoned at some two and a half months only, taking it as from the 2nd of June last, the date of the swarm; and as no swarm at all issued from the hive in 1868 (the last previous swarm having been sent out on the 12th of June, 1867), this queen cannot be less than two years old, and I believe her age must considerably exceed that. I would with pleasure send the queen to you if you cared to see her; she is still alive and well attended to; but, deprived of her former attendants, and with only a little honey to console her, I fear her term of life must now be brief indeed. —C. H. H.

[On receipt of the above we wrote for the queen, but unfortunately she had been dead five days when she reached us, and our attempt at a post-mortem examination was therefore wholly abortive. All we can say is, that she looked like a very old queen, and we shall be glad if any of our correspondents can offer a probable solution of a mystery which our own experience fails to explain.]

THE USES OF CARBOLIC ACID.

As a preliminary to an intended relation of my experience of the complaint called "dropsy" during the spring and summer, I shall describe a simple method of rescuing from their assailants weak hives that are being plundered. It is as follows:

—Early in the morning, or as soon as corsair bees are on the raid, dip a feather in carbolic acid and wet the entrance of the assailed hive all round, pouring at the same time a few drops on the landing. Repeat the dose during the day as the odour passes off. If properly managed, the inmates will remain at home ventilating, whilst not a single robber dare cross the threshold. It is even desirable that some of the robber bees should wet their feet in the acid, that on returning to their own hives they may spread consternation at home. On two occasions the process has been tried with great success, rendering altogether unnecessary the removal of the weak and plundered hives to a distance. If robbers are in possession of the hive, lift it up and pour a little of the acid on the middle of the floorboard, and then replace the hive. The robbers will speedily decamp.

I do not know of a more useful auxiliary in the apiary than carbolic acid. It is cheap, costing only 6*d* a-phial, and it is one of the best disinfectants. As ingeniously used by "Apicola" on a piece of sponge inserted in a fumigator, and blown through with the breath or a pair of bellows, it answers nearly all the purposes of smoke. True, that gentleman, when I visited his apiary in June, had some very ferocious hives, that are only amenable to tobacco smoke. Not expecting to see such tigers, I approached them without my usual accompaniment of a pipe or cigar. The consequence was, that with a panoply vulnerable at several points, I was chased over the lawn, and compelled to hide myself in the shrubbery. No Egyptians could be more ferocious. If "Apicola," however, when inspecting them will just let fall a drop or two of carbolic acid on the floorboard and on the upper interior edges of the box, I have no doubt they will quietly succumb to manipulation. Bees have been unusually ferocious this season, no doubt owing to the scarcity of food.

In this locality (Dumfries-shire) we have had a good honey harvest, but collections could not be made after the 26th of July, and up to this date, August 27th, there has been no return from the heather. It is said to be later in flowering than usual, but I suspect it is partly blasted, and that the flowers cannot open in consequence of the dry weather. "Apicola" has only obtained in supers from, I believe, eighteen stocks, 592 lbs.—R. S.

OUR LETTER BOX.

Killing Old Hens (*Brahma*).—If you mean to eat your hens or chickens either roasted or boiled, we are bound to tell you they are too old for such purposes. Your friends will paraphrase Boileau at your expense, and say of your poultry—

"Ma poulette étique, sur la table étalé,
Que du nom de "chicken" se trouve décorée.'

There are other modes of dressing the antiquities of the yard. They are capital in that most neglected but most useful article the "stock-pot." We have many times given the receipt for making old cocks and hens into pies that would tempt an epicure, and at no cost beyond trouble and painstaking. Keep them as long as they will lay, and then kill them. Let them be empty of food and let the weather be cool, that you may be able to keep them with a view to their becoming tender. Some pullets will lay in December or January; some may lay earlier.

Grain for Poultry (*A. L.*).—You may fairly believe that the best food for all poultry is that which is best in quality. No error is so great as to fall into the popular idea that any rubbish will do for that which is conventionally termed "chickens' meat." All refuse is saved in order to form part of it. Now grain is only valuable according to its weight, and those who have had to feed Ducks by hand soon learn an easy method of ascertaining that point. Food is given to Ducks in water. Take heavy oats or barley, and put them in water; they will all sink to the bottom. Take light cheap corn, and it will nearly all float on the top of the water. The necessary weight of food for feeding fowls profitably will be bought for less money laid out in the best and heaviest grain, than in that which is called cheaper because it costs less. Neglect of this truth causes many to be discouraged and to relinquish a pursuit which has been a source of pleasure to them. We feed our poultry on the best barley, the best small Indian corn, and barley or oatmeal. Our mode of feeding is to give meal slaked with water the first thing in the morning, a few handfuls of corn (barley) about ten, a regular meal of barley or Indian corn at one, and slaked meal again in the evening half an hour before dusk. Your food is right for Pigeons, but the Indian corn should be small.

Roup—Rice as Food for Chickens (*J. G.*).—Wash the head daily, or twice daily, with tepid water. Sulphate of copper, one grain daily, mixed in oatmeal mashed with ale, and plenty of green food. Separate the fowl from all others. If not better within a week kill the fowl. Rice is worse than nothing for poultry. It forms no other bone, muscle, nor flesh, and it always causes vermin. The best and cheapest food is that we have described above. You will not be troubled with laying, if you feed on rice. Chicks do not interfere with laying hens. In January four, February six, March eight, and so on increasing till in summer any moderate number; but this assumes proper and nourishing food.

Ducks when Moulting (*A Subscriber*).—The Rouen drake you saw with the brown feathers was merely in deep moult. The males of all the Duck tribe, even the handsomest, are Ducks in feather for a short time before they renew their bright colours.

Turkey Hen Disconsolate (*J. M.*).—It would have assisted us in answering if you had told us whether there was any reason to believe there was a stoppage, and that the crop was distended with food because it found no escape. If you ascertain satisfactorily there is no stoppage, and that the food in the crop is only that recently given, all you have to do will be to empty the crop, and then to feed very sparingly and frequently, allowing neither food nor water, except when given by hand. The crop will empty itself if the bird be held up by the legs with the head hanging down. When the crop is empty a table-spoonful of castor oil may be given. If the evacuations are green and slimy there will be no recovery till they are changed to brown-white and figured. Discontinue the stimulants at present. When you take to them again, give strong beer. Nettle tops should be boiled, onion tops given raw.
